Put any quantity of sea-salt, into a tubulated glass-retort, to which a large receiver is firmly luted, having a quantity of water in it, more or less, as you want your spirit of salt to be more or less strong. Having placed your retort in a sand-bath, take of concentrated oil of vitriol half as much as you put salt into the retort. Through the aperture in the upper part of the retort, pour a small quantity of the vitriolic acid; a violent effervescence will immediately arise, and white vapours will ascend, and come over into the receiver. These vapours are the marine acid in its most concentrated state; and, as they are very greedy of moisture, they will unite with the water in a very short time, unless too much oil of vitriol is put in at once; in which case, part of them will be dissipated through the small hole in the receiver. When you perceive the first fumes condensed, add a little more oil of vitriol, taking care to stop the aperture of the retort as soon as you drop in the vitriolic acid, that the marine acid may not escape. Continue this by intervals, till your acid is all put in; and then make a very gentle fire, that the retort may be no warmer than the hand can bear. This degree of heat must be continued a long time, otherwise very much of the acid will be lost. To perform this operation perfectly, no more acid should be forced over, than what the water in the receiver can take up; and by this means the operator's patience will be rewarded with a vastly larger produce of acid than can be procured by hasty distillation. When the vapours become a little more fixed, a greater heat is necessary, but nothing equal to what the nitrous acid requires.

The marine acid cannot be procured by means of combinations of the vitriolic acid with metallic and earthy bases, as the nitrous is: for though, by means of calcined vitriol, for instance, the marine acid is effectually expelled from its alkaline basis, yet it immediately combines with the calx of iron left by the vitriolic acid, and not only adheres obstinately, but even sublimes the metal; so that what little spirit can be obtained, is never pure. This inconvenience is not so great when uncalcined copperas is made use of: for the marine acid has a very strong attraction to water; which partly dissolves its union with the metalline calx. If gypsum is used, instead of calcined vitriol, not a drop of spirit will be obtained. Alum and sal catharticus amarus answer better.

To procure the Marine Acid by means of the *Nitrous*.

Take equal quantities of sea-salt, and Glauber's spirit of nitre; put the salt into a retort, and pour on it the nitrous acid; let them stand for 10 or 12 hours; then

PRACTICE then distil with a gentle heat; an acid liquor will come over, which is a compound of the nitrous and marine acids, called *aqua regis*. When the distillation is finished, and the vessels cooled, pour back the distilled liquor on the mass which is left on the retort, and distil again; the second produce will be more of the nature of spirit of sea-salt than the former. Continue to do this, pouring the distilled liquor either on the mass left in the retort, or upon fresh sea-salt, till you observe that no nitrous acid arises. No experiments have been made on this spirit of salt, by which we can judge whether it is different from that procured by the vitriolic acid or not.

To procure the Marine Acid, by distilling Salt *per se*.

²³⁰
Spirit of salt
per se. Put into a retort any quantity of common salt which has not been dried, and distil in a sand heat, till nothing more will come over. In the receiver you will have a liquor considerably more acid than vinegar, in weight about the fourth part of the salt employed. On the dry salt left in the retort, pour some water, somewhat less in quantity than the liquor which came over. Let it stand till the salt has thoroughly imbibed the moisture, and then distil again. You will again have an acid, but weaker than the former. Repeat this six or seven times; after which you will obtain no more marine acid in this way. It has been thought that sea-salt was capable of total decomposition by means of moisture alone; but that is found to be a mistake. The reason of any acid being procurable in this way, is the impurity of the common salt, which is always mixed with a quantity of sal catharticus amarus, and of marine acid combined with magnesia, from which last it is separable by moisture. If a pure salt be formed by combining marine acid with salt of soda, no spirit will be obtained.

Marine Acid combined with *Alkaline Salts*.

²³¹
Sal digestivus sylvi. **I. Vegetable fixed alkali.** This combination is accidentally formed after the distillation of volatile salts, by means of salt of tartar. (See *Alkaline Salts*.) It was formerly known by the name of *sal digestivus Sylvi*; and a process for making it was inserted in the dispensaries, under the name of *spiritus salis marini coagulatus*; but as it has been found to possess no virtues superior, or even equal, to common salt, it is fallen into disuse.

The crystals of this kind of salt are not cubical, like those of common salt, but parallelopipeds, and if thrown into the fire crack and leap about with violence. They are soluble in greater quantity by hot water than cold; and therefore are crystallized by evaporating the solution to a pellicle, and then letting it cool.—It is very remarkable, that though by a direct combination of vitriolic acid with vegetable fixed alkali, the salt called *vitriolated tartar* is formed; yet, if this alkali is once saturated with spirit of salt, so as to form a *sal digestivus*, upon the decomposition of this salt by means of oil of vitriol, the residuum of the distillation will not be a vitriolated tartar, but a salt easily soluble in water, and which bears a strong resemblance to Glauber's salt. Whether, by means of spirit of sea-salt, the vegetable alkali could be converted into the

the mineral, or salt of soda, is a question well worthy **PRACTICE** of being solved.

2. Mineral alkali. This combination is the common alimentary salt, and is never made but for experiment's sake; as the marine acid cannot be had but from sea-salt. For the extraction of this salt from seawater, see the article *SALT*.

²³²
3. Volatile alkali. The produce of this combination is the common fal ammoniac, which is used in different arts, and which has the property of making tin unite very readily with iron and copper so much used by coppermiths and in the manufactory of tinned iron.

Sal ammoniac is usually sold in large semi-transparent cakes, which are again capable of being sublimed into masses of the like kind. If they are dissolved in water, the salt very easily shoots into small crystals like feathers. Exposed to a moist air, it deliquesces. It is one of the salts which produces the most cold by its solution; so as to sink the thermometer 18 or 20 degrees, or more, according to the temperature of the atmosphere. According to Mr Gellert, a solution of fal ammoniac has the property of dissolving resins. According to Neuman, the volatility of fal ammoniac is so much diminished by repeated sublimations, that at last it remains half fluid in the bottom of the subliming vessel. In its natural state, it sublimes with a degree of heat necessary to melt lead. Pott says, that a small quantity of fal ammoniac may be produced, by distilling sea-salt with charcoal, or with alum, or by distilling marine acid with Armenian bole. The same author affirms, that the inflammability of sulphur is destroyed by subliming it with twice its quantity of fal ammoniac.

²³³
How made. The method of making this salt was long unknown; and it was imported from Egypt, where it was said to be prepared by sublimation from foot alone, or from a mixture of sea-salt, urine, and foot. That it should be produced from foot alone is very improbable; and the other method, from the known principles of chemistry, is absolutely impossible. The composition of this salt, however, being once known, there remained no other desideratum than a method of procuring those component parts of fal ammoniac sufficiently cheap, so as to afford fal ammoniac made in Britain at a price equally low with what was imported. The volatile alkali is to be procured in plenty from animal substances, or from foot; and the low price of the vitriolic acid made from sulphur, affords an easy method of decomposing sea-salt, and obtaining its acid at a low rate. A fal-ammoniac work has, accordingly, been established for several years past in Edinburgh: the principal material made choice of for procuring the volatile alkali is foot; and though no persons are admitted to see the work, the large quantities of oil of vitriol brought into it, and the quantities of genuine *sal mirabile* which are there made, evidently shew that the process for making fal ammoniac also produces Glauber's salt, by the decomposition of common salt by means of vitriolic acid. The method of conducting the process is unknown; but it is plain that there can be no other difficulty than what arises from the volatility of the vapours of the alkali and of the marine acid. In the common way of distilling those substances,

PRACTICE substances, a great part of both is lost; and if it is attempted to make fal ammoniac by combining these two when distilled by the common apparatus, the produce will not pay the cost: a little ingenuity, however, will easily suggest different forms and materials for distilling-vessels by which the marine acid and volatile alkali may be united without losing a particle of either.

If a solution of vitriolic or Glauber's secret fal ammoniac is mixed with sea-salt, the vitriolic acid seizes the alkaline basis of the sea-salt, and expels the marine acid; which immediately unites with the volatile alkali left by the vitriolic acid, and forms a true fal ammoniac. If this solution is now evaporated to dryness, and the saline mafs sublimed, the fal ammoniac rises, and leaves a combination of vitriolic acid and mineral alkali at the bottom. This fixed mafs being dissolved, filtered, and evaporated, affords Glauber's salts. This has sometimes been thought a preferable method of making fal ammoniac, as the trouble of distilling the marine acid was thereby prevented; but it is found vastly inconvenient on another account, namely, that when fal ammoniac is mixed with any fixed salt, it is always more difficult of sublimation, and a part of it even remains entirely fixed, or is destroyed. The mafs of Glauber's salt also, by reason of the inflammable and oily matter contained in impure volatile alkalies, is partly changed into a sulphureous mafs, so that the solution refuse to crystallize; at least, the operation is attended with intolerable trouble.

Marine Acid combined with Earths.

234
Fixed sal ammoniac. The combinations of this acid with earths of any kind have never been found applicable to any purpose, and therefore they are seldom made or inquired into. The combination with calcareous earth, is indeed pretty frequently made accidentally, in the distillation of volatile alkali from fal ammoniac by means of chalk, or quicklime. When melted in a crucible and cooled, it appears luminous when struck, and has been called *phosphorus scintillans*. See EARTHS.

Marine Acid combined with Metallic Substances.

236
Solution of gold in spirit of salt. 1. *Gold.* The marine acid has no action on gold in its metallic state, in whatever manner the acid be applied; but if the metal is previously attenuated, or reduced to a calx, either by precipitation from aqua regis, or by calcination in mixture with calcinable metals, this acid will then perfectly dissolve, and keep it permanently suspended. Gold, precipitated from aqua regis by fixed alkalies, and edulcorated by repeated ablutions, may be dissolved even in a very weak spirit of salt by moderate digestion. This solution appears of the same yellow colour as that made in aqua regis; gives the same purple stain to the skin, feathers, bones, and other solid parts of animals; the same violet stain to marble; and strikes the same red colour with tin. Even when common aqua regia is made use of for the menstruum, it seems to be chiefly by the marine acid in that compound liquor that the gold is held in solution. In distillation the nitrous acid arises, and the marine acid remains combined with the gold in a blood red mafs, soluble, like most of the combinations of metallic bodies with this acid, in spirit of wine. If, towards the end of the distillation, the fire is hastily

raised, part of the gold distills in a high saffron coloured liquor; and part sublimes into the neck of the retort in clusters of long slender crystals of a deep red colour, fusible in a small heat, deliquescent in the air, and easily soluble in water. By repetitions of this process the whole of the gold may be elevated, except a small quantity of white powder whose nature is not known.—This red sublimate of gold is said to be easily fusible with the heat of one's hand, and to be shown by the Papists for the blood of St Januarius; the sublimate contained in a vial, being warmed by the hands of the priests who hold it, constitutes the miracle of that saint's blood melting on his birth-day.

2. *Silver.* Strong spirit of salt corrodes leaf-silver into a white powder, but has no effect on filings or larger masses of the metal. If applied in the form of vapour, to masses of silver, and strongly heated at the same time, it readily corrodes them. Thus, if filings, grains, or plates, of silver are mixed with about twice their weight of mercury sublimite, and exposed to a moderate fire, in a retort, or other distilling vessel, a part of the marine acid in the sublimate will be separated and unite with the silver, leaving the mercury to arise in the form of mercurius dulcis. Marine acid is commonly supposed to be incapable of dissolving silver into a liquid state; but Henckel relates, that if red silver ore, which consists of silver intimately mixed with red arsenic, be digested in spirit of salt, the silver will be extracted and kept permanently dissolved.

The combination of marine acid with silver is called *Luna cornea*. The most ready way of preparing it is, by dissolving silver in the nitrous acid, and then adding spirit of salt, or a solution of sea-salt; when a precipitation instantly ensues; the marine acid expels the nitrous, and, uniting with the silver, falls to the bottom in form of a white powder. The same precipitation would take place, if a solution of silver was made in the vitriolic acid. See n° 32.

Luna cornea weighs one-fourth more than the silver employed; yet, when perfectly washed, it is quite insipid to the taste. It does not dissolve in water, spirit of wine, aqua fortis, or aqua regis; but is in some small degree acted upon by the vitriolic acid. It melts in the fire as soon as it grows red-hot; and, on cooling, forms a ponderous brownish mafs, which being cast into thin plates, becomes semi-transparent, and somewhat flexible, like horn; whence its name *luna cornea*. A stronger fire does not expel the acid from the metal, the whole concrete either subliming entire, or passing through the crucible. It totally dissolves in volatile alkaline spirits without any separation of the metal. Exposed to the fire in a close copper vessel, it penetrates the copper, and tinges it throughout of a silver colour. Kunckel observes, that when carefully prepared, melted in a glass vessel, and suffered to cool slowly, to prevent its cracking, it proves clear and transparent; and may be turned upon a lathe, and formed into elegant figures. He supposes this to be the preparation which gave rise to the notion of malleable glass.

3. *Copper.* In the marine acid, copper dissolves but slowly. The solution, if made without heat, appears at first brown; but, on standing for some time, deposits a white sediment, and becomes green. On adding fresh

237

238
Silver.

239
Luna cornea.

240
Its properties.

241
Copper.

PRACTICE copper, it becomes brown again, and now recovers its greenness more slowly than before. The white sediment, on being barely melted, proves pure and perfect copper of the same colour as at first. Copper calcined by fire, communicates a reddish colour to this acid.

242
Iron.

4. *Iron.* The marine acid acts upon iron less vehemently than the nitrous, and does not dissolve so much; nevertheless it attacks the metal briskly, so as to raise considerable heat and effervescence, and dissolve it into a yellow liquor. During the solution, an inflammable vapour arises as in the solution of this metal by vitriolic acid. This solution of iron does not crystallize. If it is evaporated, it leaves a greenish saline mass, which is soluble in spirit of wine, and runs in the air into an astringent yellow liquor. If this solution of iron is distilled, some of the acid separates, and towards the end of the distillation the spirit becomes yellow. This is followed by a yellowish, or deep reddish sublimate, which glitters like the scales of fishes; leaving behind a substance which consists of thin, glossy plates, like talc.

243
Iron volatilized.

The solution of iron in spirit of salt, with the addition of some spirit of wine, is used in medicine as a corroborant, under the name of *tinctura martis*. The sublimate of iron is also used for the same purpose, and called *ens veneris*, or *flores martiales*. It is commonly directed to be prepared by subliming iron filings and sal ammoniac together. In the process, the sal ammoniac is partly decomposed, and a caustic alkaline liquor distils. Then the undecomposed sal ammoniac, and the martial sublimate above mentioned, arise together. The sublimate has a deeper or lighter yellow colour, according as it contains more or less sal ammoniac. The name *ens veneris* is improper. It was given by Mr Boyle, who discovered this medicine. He imagined it to be a preparation of copper, having made use of a colcothar of vitriol containing both iron and copper.

244
Tinctura martis.

245
Flores martiales.

5. *Tin.* Though the concentrated marine acid has a greater attraction for tin than any other acid, it does not readily dissolve this metal while the acid is in its liquid state; but may be made to dissolve it perfectly, by the addition of a small quantity of spirit of nitre. Neuman observes, that an ounce of spirit of salt, with only a scruple of spirit of nitre, dissolved tin perfectly: but on inverting the proportions, and taking a scruple of marine acid to an ounce of the nitrous, four scruples, or four and an half, of tin, were dissolved into a thick pap; some more of the marine acid being gradually added, the whole was dissolved into a clear liquor. In making these solutions, a small quantity of black matter usually subsides.

246
Solution of tin.

The solution of tin is sometimes colourless; sometimes of a bluish, or yellow colour, according to different circumstances of the process. It is of the greatest consequence in dyeing, by not only heightening the colours, but making them more durable. (See DYEING.) It shoots into small crystals; and, if inspissated, deliquesces in the air.

247
Smoking liquor of Libavius.

Marine acid in its concentrated state velatizes tin, and forms with it a thick liquor, which, from its inventor, is called *smoking liquor of Libavius*. To make this smoking liquor, an amalgam (See Sect. III.) must be made of four parts of tin and five of mercury. This

amalgam is to be mixed with an equal weight of corrosive mercury, by triturating the whole together in a glass mortar. The mixture is then to be put into a glass retort, and the distillation performed with a fire gradually increased. A very smoking liquor passes into the receiver; and towards the end of the distillation, a thick, and even concrete matter. When the operation is finished, the liquor is to be poured quickly into a crystal glass-bottle, with a glass stopper. When this bottle is opened, a white, copious, thick, and poignant fume issues, which remains long in the air without disappearing.

The acid in this liquor is far from being saturated, and is capable of still dissolving much tin in the ordinary way. From this imperfect saturation, together with its concentration, proceeds partly its property of smoking so considerably: nevertheless, some other cause probably concurs to give it this property; for though it smokes infinitely more than the most concentrated spirit of salt, its vapours are, notwithstanding, much less elastic. It has all the other properties of concentrated marine acid when imperfectly saturated with tin. If it is diluted with much water, most of the metal separates in light white flocks. In dyeing it produces the same effects as solution of tin made in the common way. If the distillation is continued after the smoking liquor of Libavius has come over, the mercury of the corrosive sublimate will then arise in its proper form.

7. *Lead.* Marine acid, whether in its concentrated or diluted state, has little effect upon lead, unless assisted by heat. If spirit of salt is poured on filings of lead, and the heat is increased so as to make the liquor boil and distil, a part of the acid will be retained by the metal, which will be corroded into a saline mass; and this, by a repetition of the process, may be dissolved into a limpid liquor. If lead is dissolved in aqua fortis, and spirit of sea-salt, or sea-salt itself, added, a precipitation of the metal ensues; but if some aqua regia is added, the precipitate is redissolved.

The combination of lead with marine acid, has, when melted, some degree of transparency and flexibility like horn; whence, and from its resemblance to luna cornea, it is called *plumbum corneum*. This substance is used in preparing phosphorus, according to Mr Margraaf's method.

8. *Quicksilver.* Marine acid in its limpid state, whether concentrated or diluted, has no effect upon quicksilver, even when assisted by a boiling heat; but if mercury is dissolved in the vitriolic or nitrous acids, and sea-salt, or its spirit, is added to the solution, it immediately precipitates the quicksilver in the same manner as it does silver or lead. If concentrated marine acid, in the form of vapour, and strongly heated, meets with mercury in the same state, a very intimate union takes place; and the produce is a most violent corrosive and poisonous salt, called *corrosive sublimate mercury*. This salt is soluble, though sparingly, in water; but is far from being perfectly saturated with mercury; for it will readily unite with almost its own weight of fresh quicksilver, and sublime with it into a solid white mass (which, when levigated, assumes a yellowish colour) called *mercurius dulcis*, *aquila alba*, or *calomel*.

PRACTICE

252
Different
methods of
making.

There have been many different ways of preparing corrosive mercury, recommended by different chemists. Neuman mentions no fewer than ten. 1. From mercury, common salt, nitre, and vitriol. 2. From mercury, common salt, and vitriol. 3. Mercury, common salt, and spirit of nitre. 4. Solution of mercury in aqua fortis and salt. 5. Solution of mercury in aqua fortis, and spirit of salt, or the white precipitate. 6. Mercury, common salt, nitre, and oil of vitriol. 7. Edulcorated turbit mineral, and common salt. 8. Red precipitate, common salt, and oil of vitriol. 9. Edulcorated turbit mineral, and spirit of salt. 10. Mercury, fil ammoniac, and oil of vitriol.

From a view of these different methods, it is evident, that the intention of them all is to combine the marine acid with quicksilver; and as this combination can be effected without making use of the nitrous acid, the greatest chemists have imagined that this acid, which is by far the most expensive of the three, might be thrown out of the process altogether, and sublimate be more conveniently made by directly combining marine acid and mercury in a process similar to the distillation of spirit of salt. This method was formerly recommended by Kunckel; then published in the memoirs of the Academy of Sciences for 1730; and has been adopted and recommended by Dr Lewis.

The process consists in dissolving mercury in the vitriolic acid, as directed for making turbit mineral, (see n° 153). The white mass remaining on the effication of this solution is to be triturated with an equal weight of dried salt, and the mixture is then to be fublimed in a sand-heat; gradually increasing the fire till nothing more arises.

253
Differences
of quality.

Neuman observes, that there is a considerable difference in the quality of sublimate made by the different methods he mentions; particularly in those made with, or without nitre. This we have also found to be the case; and that sublimate made without the nitrous acid is never so corrosive, or soluble in water, as that which is made with it: nor will it afterwards take up so large a quantity of crude mercury as it otherwise would, when it is to be formed into calomel. The above process, therefore, tho' very convenient and easy, is to be rejected; and some other, in which the nitrous acid is used, substituted in its stead. This is another instance where a rigid adherence to the established rules of chemistry will lead people into a mistake. See n° 117.

From Tachenius, Neuman gives us the following process, which he says was the method of making sublimate at London, Venice, and Amsterdam. Two hundred and eighty pounds of quicksilver; 400 pounds of calcined vitriol, 200 pounds of nitre, the same quantity of common salt, and 50 pounds of the caput mortuum remaining after a former sublimation, or (in want of it) of the caput mortuum of aqua fortis, making, in all, 1130 pounds, are well ground, and mixed together; then set to sublime in proper glass vessels placed in warm ashes; the fire is increased by degrees, and continued for five days and nights. In the making such large quantities, he says, some precautions are necessary, and which those constantly employed herein are best acquainted with. The principal are, the due mixture of the ingredients, which in

some places is performed in the same manner as that of the ingredients for gun-powder, (see GUN-POWDER): that a head and receiver be adapted to the subliming glass, to save some spirit of nitre which will come over. (Here a bent tube of glass will answer the purpose, as already mentioned, n° 80). The fire must not be raised too hastily. When the sublimate begins to form, the ashes must be removed a little from the sides of the glass, or the glass cautiously raised up a little from the ashes. (This last, we think, is highly imprudent.) Lastly, the laboratory must have a good chimney, capable of carrying off the noxious fumes. The above-mentioned quantities commonly yield 260 pounds of sublimate; the 290 pounds of quicksilver gaining 80 from the 200 pounds of sea-salt. The makers of sublimate in France, he says, employ, in one operation, only 20 pounds of mercury. This they dissolve in aqua fortis, evaporate the solution to dryness, mix the dry matter with 20 pounds of decrepitated sea-salt and 60 of calcined vitriol, and then proceed to sublimation.

The above processes, particularly the last, are unexceptionable as to the production of a sublimate perfectly corrosive; but the operation, it is evident, must be attended with considerable difficulty, by reason of the large quantity of matter put into the glass at once. We must remember, that always on mixing a volatile salt with a quantity of fixed matter, the sublimation of it becomes more difficult than it would have been had no such matter been mixed with it. It is of considerable consequence, therefore, in all sublimate operations, to make the quantity of matter put into the glass as little as possible. It would seem more proper, therefore, instead of the calcined vitriol used in the processes last mentioned, to dissolve the mercury in the vitriolic acid, as directed for turbit mineral, and sublime the dry mass mixed with nitre and sea-salt.

It has been said, that corrosive sublimate mercury was frequently adulterated with arsenic; and means have even been pointed out for detecting this supposed adulteration. These means are, to dissolve a little of the suspected salt in water, and add an alkaline lixivium to precipitate the mercury. If the precipitate was of a black colour, it was said to be a certain sign of arsenic. This, however, shews nothing at all, but that either the alkali contains some inflammable matter, which, joining with the precipitate, makes it appear black; or that the sublimate is not perfectly corrosive; for if a volatile alkali is poured on levigated *mercurius dulcis*, the place it touches is instantly turned black.

Mercurius dulcis, or calomel, is prepared by mixing *Mercurius* equal parts, or, at least, three of quicksilver, with four *dulcis*. of sublimate; after being thoroughly ground together in a glass or stone mortar, they are to be poured through a long funnel into a bolt-head, and then sublimed. The medicine has been thought to be improved by repeated sublimate operations, but this is found to be a mistake.

g. *Zinc*. This semi-metal dissolves readily in the marine acid, into a transparent colourless liquor. It is volatilized, as well as most other metallic substances, by this combination, as appears from the following process delivered by Neuman.

257
Zinc volat-
ilized.

"Equal parts of filings of zinc and powdered fal ammoniac being mixed together, and urged with a gradual fire in a retort; at first arofe, in a very gentle heat, an excessively penetrating volatile spirit, fo strong as to ftrike a man down, who fhould inadvertently receive its vapour freely into the nofe. This came over in fubtile vapours, and was followed by a fpirit of falt in denfe white fumes. In an open fire, white flowers fucceeded; and, at length, a reddifh and a black butter. In the bottom of the retort was found a portion of the zinc, in its metalline form, with a little ponderous and fixed butyraceous matter, which liquified in the air. The lump was far more brittle than zinc ordinarily is; of a reddifh colour on the outfide, and blackifh within. The bottom of the retort was variegated with yellow and red colours, and looked extremely beautiful. The remaining zinc was mixed afresh with equal its weight of fal ammoniac, and the procefs repeated. A volatile alkaline fpirit and marine acid were obtained as at firft; and in the retort was found only a little black matter. When the zinc was taken at firft in twice the quantity of the fal ammoniac, the part that preferved its metallic form proved lefs brittle than in the foregoing experiment; and the retort appeared variegated in the fame manner; on endeavouring to rectify the butter, the retort parted in two, by the time that one half had diftilled." The nature of this combination is unknown.

258

Butter of
antimony.

10. *Regulus of antimony.* This femi-metal cannot be united with the marine acid, unlefs the latter is in its moft concentrated ftate. The produce is an excessively cauftic thick liquid, called *butter of antimony.* The procefs for obtaining this butter, is fimilar to that for diftilling the fuming fpirit of Libavius. (See n^o 247). Either crude antimony, or its regulus, may be ufed; for the fpirit of falt will attack the reguline part of this mineral, without touching the fulphureous. Three parts of corrofive fublimat are to be mixed with one of crude antimony; the mixture to be digefted in a retort fet in a fand heat; the marine acid in the fublimat will unite with the reguline part of the antimony. Upon increafing the fire, the regulus arifes, difolved in the concentrated acid, not into a liquid form, but that of a thick unctuous fubftance like butter, from whence it takes its name. This fubftance liquifies by heat, and requires the cautious application of a live coal to melt it down from the neck of the retort. By rectification, or expofure to the air, it becomes fluid, like oil, but ftill retains the name of butter. If water is added to butter of antimony, either when in a butyraceous form, or when become fluid by rectification, the antimony is precipitated in a white powder called *powder of algaroth*, and improperly *mercurius vitæ*. This powder is a violent and very unfafe emetic. The butter itfelf was formerly ufed as a cauftic; but it feems totally neglected in the prefent practice.

When the mercurius vitæ precipitates, the union between the marine acid and regulus is totally difolved; fo that the powder, by frequent washings, becomes perfectly free from every particle of acid, which unites with the water made ufe of, and is then called, very improperly, *phloftophic fpirit of vitriol*.

11. *Regulus of cobalt.* Pure fpirit of falt difolves this femi-metal into a reddifh yellow liquor, which immediately becomes green from a very gentle warmth. On faturating the folution with urinous fpirits, the precipitate appears at firft white, but afterwards becomes blue, and at length yellow. If the nitrous acid is added to folutions of regulus of cobalt, they affume a deep emerald green when moderately heated, and on cooling become red as at firft. Duly evaporated, they yield rofe-coloured cryftals, which change their colour by heat in the fame manner. This folution makes a curious fymphathetic ink, the invention of which is commonly afcribed to M. Hellot, though he himfelf acknowledges that he received the firft hint of it from a German chemift in 1736. Any thing wrote with this folution is invifible when dry and cold; but affumes a fine green colour when warm, and will again difappear on being cooled; but if the heat has been too violent, the writing ftill appears. Mr Hellot obferves, that if nitre or borax be added to the nitrous folution, the characters wrote with it become rofe-coloured when heated; and if fea-falt is afterwards paffed over them, they become blue; that with alkali fufficient to faturate the acid, they change purple, and red with heat.

Arsenic. This fubftance is foluble in all acids; but the nature of the compounds formed by fuch an union is little known. If half a pound of arfenic is diftilled with one pound of corrofive fublimat, a thin fuming liquor and a butyraceous fubftance will be obtained, as in making the fuming liquor of Libavius, (fee n^o 247). By repeated rectifications, this butter may be almoft all converted into fpirit. If equal parts of the arfenic and fublimat are ufed, a ponderous black oil comes over along with the fpirit, which cannot be mixed with it. By rectification in a clean retort, they will become clear, but ftill will not incorporate. If they are now returned upon the red mafs remaining in the firft retort, and again diftilled, a much more ponderous oil than the former will be obtained.

260
Oil of arse-
nic.

Marine Acid combined with Inflammable Substances.

The acid of fea-falt is very little difpofed to contract any union with the phlogifton, while in a liquid ftate; and much lefs fo, even in its moft concentrated ftate, than either the vitriolic or nitrous. Mr Beaumé, however, has found that a fmall quantity of ether, fimilar to that prepared with the vitriolic and nitrous acids, may be obtained by caufing the fumes of the marine acid unite with thofe of fpirit of wine. Others, and particularly fome German chemifts, attempted to make this liquor, by employing a marine acid previously combined with metallic fubftances, fuch as butter of antimony. The *fuming liquor of Libavius*, (n^o 247), fucceeds beft. If equal parts of this liquor, and highly rectified fpirit of wine are diftilled together, a confiderable quantity of true ether is produced; but which, like the vitriolic and nitrous ether, muft be rectified, in order to its greater purity. The tin contained in the fuming liquor is feparated, and precipitated in white powder. In this procefs, the acid is probably more difpofed to unite with the fpirit of wine, by having already begun to combine with the inflammable principle of the metal.

261
Marine
ether.

PRACTICE

262
Attraction
for phlogi-
ston.

Dr Priestley has observed, that the pure marine acid, when reduced to an invisible ærial state, has a strong affinity with phlogiston, so that it decomposes many substances that contain it, and forms with them an air permanently inflammable. By giving it more time, it will extract phlogiston from dry wood, crusts of bread not burnt, dry flesh; and, what is still more extraordinary, from flints.

Essential oil of mint absorbed the marine acid air pretty fast, and presently became of a deep brown colour. When taken out of this air, it was of the consistency of treacle, and sunk in water, smelling differently from what it did before; but still the smell of the mint was predominant. Oil of turpentine was also much thickened; and became of a deep brown colour, by being saturated with acid air. Ether absorbed the air very fast; and became first of a turbid white, and then of a yellow and brown colour. In one night a considerable quantity of strongly inflammable air was produced.

Having once saturated a quantity of ether with acid air, he admitted bubbles of common air to it, through the quicksilver by which it was confined, (see AIR, n° 49.) and observed that white fumes were made in it, at the entrance of every bubble, for a considerable time. Having, at another time, saturated a small quantity of ether with this kind of air, and the vial which contained it happening to be overturned, the whole room was instantly filled with a white cloud, which had very much the smell of ether, but peculiarly offensive. Opening the door and window of the room, this light cloud filled a long passage, and another room. The ether, in the mean time, was seemingly all vanished; but, some time after, the surface of the quicksilver in which the experiment had been made, was covered with a very acid liquor, arising probably from the moisture in the atmosphere, attracted by the acid vapour with which the ether had been impregnated. This seems to shew, that, however much disposed the marine acid may be to unite with phlogistic matters when in its ærial state, the attraction it has for them is but very slight, and still inferior to what it has for water.

Camphor was presently reduced into a fluid state by imbibing this acid air; but there seemed to be something of a whitish sediment in it. After continuing two days in this situation, water was admitted to it, upon which the camphor immediately resumed its former solid state; and to appearance was the same substance that it had been before.

Strong concentrated oil of vitriol, being put to marine acid air, was not at all affected by it in a day and a night. In order to try whether it would not have more power in a condensed state, it was compressed with an additional atmosphere; but, on taking off this, the air expanded again, and was not in the least diminished. A quantity of strong spirit of nitre was also put to it without any sensible effect. From these last experiments it appears, that the marine acid is not able to dislodge the other acids from their union with water.

IV. OF THE FLUOR ACID.

The discovery of this curious acid we owe to

Mr Scheele, a Swedish chemist, from whom it is often distinguished by the name of the *Swedish acid*. Mr Scheele was of opinion, that this acid is one of the component parts of a sparry substance called *fluor sparatus*. This substance he reckons to be composed of a calcareous earth, and the particular species of acid obtained from it by distillation; and accordingly relates, that he produced the same kind of spar by adding this acid to lime-water. The most remarkable circumstance, however, attending this acid is, that when the vapour of it is mingled with water placed in the receiver for that purpose, a white spot is formed on the surface of the water, which, by degrees, spreads entirely over the surface of it. On agitating the receiver, this crust, being broken into several pieces, was thereby sunk to the bottom. On the contact of the succeeding vapours, a new crust was immediately formed, and the water soon became considerably acid. The white crust, which first appeared on the surface of the water in the receiver, and which afterwards sunk to the bottom, was found by him to possess all the properties of a real *fixe*, or stony substance. It could not be dissolved in any of the acids, nor would it form any paste with water. It dissolved in an alkaline lixivium; suffered no change from fire, when exposed to its single action; but, on the addition of an alkali, melted into glass. This glass, mixed with thrice its own quantity of vegetable fixed alkali, melted into a blue mass; which, being pounded, and put into a damp cellar, very soon ran *per deliquium*, and turned into a gelatinous substance. An acid precipitated a powder from it; and lastly, it was dissolved in borax without the least effervescence.

The inference drawn by the author from these circumstances is, that this *fixe*, or stony crust, thus produced from the sparry fluor, is solely compounded of the acid of spar united with the particles of the water in the receiver. From some other processes he concludes, that the whole of this singular acid may be converted into flint by the addition of water: and that the water is a necessary ingredient in this compound body, he infers from other processes; in which it appears, that when the receiver contained alcohol, oil of olives, or oil of vitriol, no stony crust was formed; and that it appeared only when there was water in the receiver.

His method of operating upon this substance was, to distil it with oil of vitriol in glass vessels; and another very remarkable fact concerning it was, that all those vessels were so corroded, that holes were made through them. This occasioned some doubt with respect to the stony crust formed on the water in the receiver, as it might reasonably enough be imagined that it proceeded from the particles of sand or flint originally existing in the glass, which the acid parted with on its meeting with the water. Mr Scheele, however, fell upon a way to obviate this objection, by exposing a piece of wet charcoal to the vapours of the acid, as they arose from the mixture of oil of vitriol and spar, and found the same stony crust formed upon it as when the vapour was suffered to mingle directly with water in the receiver.

Mr Boulanger, who examined this acid with great care, concludes, that it is the acid of sea-salt, joined with

PRACTICE

263
Whence
procured.

PRACTICE with an earthy substance, but does not pretend to decide this matter with certainty. Mr Scheele himself was of opinion, that the fluor acid was distinct from the marine and all other acids; because he found it dislodged from the spar by the nitrous and marine, as well as by the vitriolic acid: but those who repeated the experiments after him could procure no fluor acid, except by using the vitriolic.

ad 264
Fluor acid
air.

Dr Priestley, who had exhibited other acids in the form of air, was very desirous of making similar experiments on this. Accordingly, having put some pounded spar into a vial, and poured oil of vitriol upon it, he filled it with a tube, and the other apparatus for receiving the air which should be expelled from it; (see AIR, n° 49.) He observed, that when the fluor acid vapour issued out of the tube, and mingled with the external air, a permanent white cloud was formed; which he attributes to the attachment of the acid to the water contained in the air. The moment that water came into contact with this air, the surface of it became white and opaque, by a stony film; which, forming a separation between the air above and the water below, considerably retarded the ascent of the water, till the air insinuating itself through the pores and cracks of the crust, the water necessarily rose as the air diminished; and, breaking the crust, presented a new surface to the air, which immediately was covered with another crust. Thus one stony incrustation was formed after another, till every particle of the air was united to the water, and the different films being collected and dried, formed a white powdery substance, generally a little acid to the taste; but when washed in much pure water, was perfectly insipid. The property of corroding glass he found to belong to this air only when pretty hot.

The Doctor is of opinion, that this acid is only the vitriolic, loaded with plenty of sparry crust, and volatilized by a little phlogiston. What he reckons an experiment sufficient to determine this matter, is, that having pressed out the stony matter with which the acid liquor in the receiver was impregnated, he found it to yield air which formed no crust on the surface of other water, but was imbibed by it in the same manner as the vitriolic acid air he had formerly made experiments on. The proof, however, would have been more convincing to chemists, had he formed a little vitriolated tartar, or Glauber's salt, by uniting it with a fixed alkali.

265
How prepared.

V. Of the SAL SEDATIVUS, or Acid of Borax.

This is a saline substance of a very singular nature, and hitherto found no where but in borax itself. From this it is separable either by sublimation or crystallization. The method by sublimation, is that recommended by Homberg, who first discovered the sedative salt. His process consists in mixing green vitriol with borax, dissolving them in water, filtering the solution, and evaporating till a pellicle appears: the liquor is then to be put into a small glass alembic, and the sublimation promoted till only a dry matter remains in the cucurbit. During this operation, the liquor passes into the receiver; but the internal surface of the capital is covered with a saline matter forming very small, thin, laminated crystals, very shining, and

very light. This is the sedative salt. The capital is then to be unluted, and the adhering salt swept off with a feather; the part of the liquor, which passed last into the receiver, is to be poured on the dry matter in the cucurbit, and a new sublimation is to be promoted as before, by distilling till the matter in the cucurbit is dry. These operations are to be frequently repeated, in the same manner, till no more sedative salt can be obtained.

To obtain the sedative salt by crystallization, borax is to be dissolved in hot water; and to this solution any one of the three mineral acids is to be gradually added, by a little at a time, till the liquor be saturated, and even have an excess of acid, according to Mr Beaumé's process. The liquor is then to be left in a cold place; and a great number of small, shining, laminated crystals will be formed: these must be washed with a little very cold water, and drained upon brown paper. The sedative salt obtained by this process is somewhat denser than that obtained by sublimation; the latter being so light, that 72 grains are sufficient to fill a large vial.

Sedative salt, though thus capable of being once sublimed, is not, however, volatile: for it arises only by means of the water of its crystallization; and when it has once lost its water by drying, it cannot be raised into vapours by the most violent fire, but remains fixed, and melts into a vitreous matter, like borax itself. This glass is soluble in water, and then becomes sedative salt again. A great quantity of water is required to dissolve the sedative salt, and much more of cold than of boiling water; whence it is crystallizable by cold, as it also is by evaporation; a singular property, which scarce belongs to any other known salt.

This substance has not an acid, but a somewhat bitterish taste, accompanied with a slight impression of coolness. It nevertheless unites with alkaline salts as acids do, and forms with them neutral salts. It is soluble in spirit of wine, to which it communicates the property of burning with a green flame. It makes no change on the blue colour of vegetables, as other acids do. It expels the other acids from their basis, when distilled with a strong heat; though these are all capable of expelling it in the cold, the acid of vinegar not excepted.

The composition of sedative salt is very much unknown, as no means sufficient for its decomposition have hitherto been found out. Mr Bourdelin who made many experiments on this salt, found that it was unalterable by treatment with inflammable matters, with sulphur, with mineral acids disengaged, or united with metallic substances, and with spirit of wine. He could only perceive some marks of an inflammable matter, and a little marine acid. The former discovered itself by its communicating a sulphureous smell to the vitriolic acid employed; and the latter by a white precipitate formed, in a solution of mercury in the nitrous acid, by the liquor which came over on distilling the salt with powdered charcoal.

Mr Cadet, in the Memoirs of the Royal Academy of Sciences for 1766, has given an account of some experiments made by him on borax and its acid: from which he infers, (1.) That the acid contained in borax itself is the marine, and not sedative, salt. (2.) That

it

PRACTICE it is the marine, he proves by having made a corrosive sublimate with this acid and *mercurius precipitatus per se*. That sedative salt does not enter the composition of borax itself, he proves, by the impossibility of recomposing borax from uniting the sedative salt with fusible alkali. The salt so produced, he owns, is very like borax, but unfit for the purposes of folding metals as borax is. He therefore thinks, that, in the decomposition of borax, the principles of the salt are somewhat changed, by the addition of that acid which extricates the sedative salt; and that this salt is composed of the marine acid originally existing in the borax, of the vitriolic acid employed in the operation, and of a vitrescible earth. (If this is true, then sedative salt either cannot be procured by any other acid than the vitriolic, or it must have different properties according to the acid which procures it.) The vitrescible earth, he says, is that which separates from borax during its solution in water, and which abounds more in the unrefined than refined borax, and which he thinks consists of a calx of copper, having obtained a regulus of copper from it. As he has never been able, however, to compose borax by the union of these ingredients, his experiments are by no means decisive.

Sedative Salt combined with *Alkalies*.

With the vegetable alkali this salt forms a compound very much resembling borax itself in quality; but in what respects it differs from, or how far it is applicable to the purposes of, borax, hath not yet been determined.

With the mineral alkali, this salt has generally been thought to recompose borax: and, though Mr Cadet has denied this, yet as his experiments are hitherto imperfect and unsupported, we shall here give the history of that salt, as far as it is yet known.

This salt is prepared in the East Indies. It is said, that from certain hills in these countries there runs a green saline liquor, which is received in pits lined with clay, and suffered to evaporate with the sun's heat; that a bluish mud which the liquor brings along with it is frequently stirred up, and a bituminous matter, which floats upon the surface, taken off; that when the whole is reduced to a thick consistence, some melted fat is mixed, the matter covered with vegetable substances and a thin coat of clay; and that when the salt has crystallized, it is separated from the earth by a sieve. In the same countries is found native the mineral alkali in considerable quantity; sometimes tolerably pure, at other times blended with heterogeneous matters of various kinds. This alkali appears to exist in borax, as a Glauber's salt may be formed from a combination of borax with vitriolic acid.

Borax, when imported from the East Indies, consists of small, yellow, and glutinous crystals. It is refined, some say, by dissolving it in lime-water; others, in alkaline lixivium, or in a lixivium of caustic alkali; and, by others, in alum-water. Refined borax consists of large, eight-sided crystals, each of which is composed of small, soft, and bitterish scales. Crystals of this size can by no means be obtained by dissolving unrefined borax in common water. The crystals ob-

tained in this way are extremely small, and differ considerably from the refined borax of the shops; inasmuch that Cramer calls the large crystals, not a purified, but an adulterated borax. When dissolved in lime-water, the borax shoots into larger crystals; and largest of all, when the vessel is covered, and a gentle warmth continued during the crystallization. During the dissolution, borax appears glutinous, and adheres in part to the bottom of the vessel. From this glutinous quality, peculiar to borax among the salts, it is used by dyers for giving a gloss to silks.

All acids dissolve borax slowly, and without effervescence. It precipitates from them most, but not all, metallic substances; along with which a considerable part of the borax is generally deposited. It does not absorb the marine acid of luna cornea, or of mercury sublimate. It melts upon the surface of the fire without uniting, and suffers the latter to rise unchanged; the borax in both cases becomes coloured; in the first, milky with red streaks; in the latter, amethyst or purple. Mixed with sal ammoniac, it extricates the volatile alkali, and retains the acid; but mixed with a combination of the marine acid with calcareous earths, it unites with the earth, and extricates the acid. It extricates the acid of nitre without seeming to unite with the alkaline basis of that salt; nor does it mingle in fusion with the common fixed alkaline salts, the borax flowing distinct upon their surface. A mixture of borax with twice its weight of tartar, dissolves in one sixth of the quantity of water that would be necessary to dissolve them separately: the liquor yields, on inspissation, a viscous, tenacious mass like glue; which refuses to crystallize, and which deliquesces in the air. Borax affords likewise a glutinous compound with the other acids, except the vitriolic; whence this last is generally preferred for making the sedative salt. It proves most glutinous with the vegetable, and least with the marine. With oils both expressed and distilled, it forms a milky, semi-saponaceous compound. It partially dissolves in spirit of wine. In conjunction with any acid, it tinges the flame of burning matters green; the precipitate thrown down by it from metallic solutions has this effect. It does not deflagrate with nitre. Fused with inflammable matters, it yields nothing sulphureous as those salts do which contain vitriolic acid. By repeatedly moistening it when considerably heated, it may be entirely sublimed.

Borax renders all earths and stones fusible by fire, and hence is used for the essaying of ores. It also facilitates the fusion of metals; and is particularly useful when small particles of metal, mixed with dirt and ashes, are to be melted together; as it promotes the fusion of the metal, and the vitrification of the other matters, by which the particles of metal may disengage themselves, and collect into one mass. It is further useful in the fusion of metals, as it defends their surfaces from the combined action of air and fire, by which imperfect metals are calcined. A principal use of borax is in the folding of metals; which it probably does by accelerating the fusion of the surfaces of the metals to be joined, and by clearing them of any calx or other matter by which they might be prevented from being perfectly joined to one another.

272
Its properties.

270
Borax.

271
Refined.

PRACTICE Borax retains a good quantity of water in its crystals; by which it melts and swells up in a heat insufficient to vitrify it. It is then spongy and light, like calcined alum; but, on increasing the fire, it flows like water.

273
How procured.

VI. Of the ACETOUS ACID and its Combinations.

This acid is plentifully obtained from all vinous liquors, by a fermentation of a particular kind, (see **FERMENTATION**, and **VINEGAR**.) It appears first in the form of an acid liquor, more or less deeply coloured, as the vinegar is more or less pure. By distillation in a common copper-still, with a pewter head and worm, this acid may be separated from many of its oily and impure parts. Distilled vinegar is a purer, but not a stronger acid, than the vinegar itself: for the acid is originally less volatile than water, though, by certain operations, it becomes more so. After vinegar has been distilled to about $\frac{1}{5}$ of its original bulk, it is still very acid, but thick and black. This matter continues to yield, by distillation, a strong acid spirit, but tainted with an empyreumatic oil. If the distillation is still continued, a thick black oil continues to come over; and at last some volatile alkali, as in the distillation of animal substances. The caput mortuum left in the distilling vessel, being calcined in an open fire, and afterwards lixiviated, yields some fixed alkaline salt.

271
Sal diuretic.

Acetous Acid combined with Alkaline Salts.

1. **Vegetable Alkali.** The produce of this combination is the *terra foliata tartari*, or sal diuretic of the shops; but to prepare this salt of a fine white flaky appearance, which is necessary for sale, is a matter of some difficulty. The best method of performing this operation is, after having saturated the alkali with the vinegar, which requires about 15 parts of common distilled vinegar to one of alkali, to evaporate the liquor to dryness; then melt the saline mass which remains with a gentle heat; after which it is to be dissolved in water, then filtered, and again evaporated to dryness. If it is now dissolved in spirit of wine, and the liquid abstracted by distillation, the remaining mass being melted a second time, will, on cooling, have the flaky appearance desired.

A good deal of caution is necessary in the first melting; for the acetous acid is easily dissippable, even when combined with fixed alkali, by fire. It is proper, therefore, that, when the salt is melted, a little should be occasionally taken out, and put into water; and, when it readily parts with its blackness to the water, must then be removed from the fire.

275
Acetous acid with fusible alkali.

Fusible Alkali. This alkali combined with the acetous acid, forms a salt whose properties are not well known. Dr Lewis affirms, that it is nearly similar to the *terra foliata tartari*. The author of the Chemical Dictionary, again, maintains it to be quite different: particularly that it crystallizes well, and is not deliquescent in the air; whereas the former cannot be crystallized; and even when obtained in a dry form, unless great care is taken to exclude the air, will pre-

del.

Volatile Alkali. This combination produces a salt so exceedingly deliquescent that it cannot be procured

in a dry form without the greatest difficulty. In a liquid state, it is well known in medicine, as a sudorific, by the name of *spiritus mindereri*. It may, however, be procured in a dry form, by mixing equal parts of vitriolic sal ammoniac and *terra foliata tartari*, and subliming the mixture with a very gentle heat. When the salt is once procured, the utmost care is requisite to preserve it from the air.

Acetous Acid combined with Earths.

Combinations of this kind are but little known. With the calcareous and argillaceous earths compounds of an astringent nature are formed. According to the author of the Chemical Dictionary, the salt resulting from a combination of vinegar with calcareous earth easily crystallizes, and does not deliquesce. With magnesia the acetous acid does not crystallize; but, when inspissated, forms a tough mass, of which two drachms, or two and a half, are a brisk purgative.

Acetous Acid combined with Metallic Bodies.

1. **Copper.** Upon this metal the acid of vinegar does not act briskly, until it is partly at least calcined. If the copper is previously dissolved in a mineral acid, and then precipitated, the calx will be readily dissolved by the acetous acid. The solution is of a green colour, and beautiful green crystals may be obtained from it. The solution, however, is much more easily effected, by employing verdigrise, which is copper already united with a kind of acetous or tartareous acid, and very readily dissolves in vinegar. The crystals obtained by this process are used in painting, under the name of *distilled verdigrise*.

2. **Iron.** Vinegar acts very readily upon iron, and dissolves it into a very brown, and almost black liquor, which does not easily crystallize, but, if inspissated, runs per deliquium. This liquor is employed in the printing of linens, calicoes, &c. being found to strike a finer black with madder, and to injure the cloth less, than solutions of iron in the other acids.

3. **Lead.** The acetous acid dissolves lead in its metallic state very sparingly; but if the metal is calcined, it acts upon it very strongly. Even after lead is melted into glass, the acetous acid will receive a strong impregnation from it, and hence it is dangerous to put vinegar into such earthen vessels as are glazed with lead. In the metallic state, only a drachm of lead can be dissolved in eight ounces of distilled vinegar.

If lead is exposed to the vapours of warm vinegar, it is corroded into a kind of calx, which is used in great quantities in painting, and is known by the name of *cerusi*, or *white lead*. The preparation of this pigment has become a distinct trade, and is practised in some places of this kingdom where lead is procurable at the lowest price. The process for making cerusi is thus given by the author of the Chemical Dictionary.

"To make cerusi, leaden plates rolled spirally, so that the space of an inch shall be left between each circunvolution, must be placed vertically in earthen pots of a proper size, containing some good vinegar. These leaden rolls ought to be so supported in the pots that

PRACTICE

Lead.

281
Cerusi.

PRACTICE that they do not touch the vinegar, but that the acid vapour may circulate freely betwixt the circumvolutions. The pots are to be covered, and placed in a bed of dung, or in a sand-bath, by which a gentle heat may be applied. The acid of vinegar being thus reduced into vapour, easily attaches itself to the surface of these plates, penetrates them, and is impregnated with the metal, which it reduces to a beautiful white powder called *cerufs*. When a sufficient quantity of it is collected on the plates, the rolls are taken out of the pots, and unfolded; the *cerufs* is then taken off, and they are again rolled up, that the operation may be repeated."

"In this operation, the acid being overcharged with lead, this metal is not properly in a saline state; hence *cerufs* is not in crystals, nor is soluble in water: but a saline property would render it unfit for painting, in which it is chiefly employed."

232
Observations on the process for *cerufs*.

Though this process may in general be just, yet there are certainly some particulars necessary to make *cerufs* of a proper colour, which this author has omitted; for though we have carefully treated thin plates of lead in the manner he directs, yet the calx always turned out of a dirty grey colour. It is probable, therefore, that after the lead has been corroded by the steam of vinegar, it may be washed with water slightly impregnated with the vitriolic and nitrous acids.

This preparation is the only white hitherto found fit for painting in oil: but the discovery of another would be very desirable, not only from the faults of *cerufs* as a paint, but also from its injuring the health of persons employed in its manufacture, by affecting them with a severe colic; which lead, and all its preparations, frequently occasion.

283
Sugar of lead.

If distilled vinegar is poured on white lead, it will dissolve it in much greater quantity than either the lead in its metallic form, or any of its calces. This solution, filtered and evaporated, shoots into small crystals, of an austere sweetish taste, called *sugar of lead*. These are used in dyeing, and externally in medicines. They have been even given internally for spitting of blood. This they will very certainly cure; but, at the same time, they as certainly kill the patient by bringing on other diseases. If these crystals are repeatedly dissolved in fresh acids, and the solutions evaporated, an oily kind of substance will at last be obtained, which can scarcely be dried.

284
Inflammable spirit from sugar of lead.

From all the metallic combinations of the acetous acid, it may be recovered in an exceedingly concentrated form, by simple distillation, sugar of lead only excepted. If this substance is distilled in a retort with a strong heat, it hath been said that an inflammable spirit, and not an acid, comes over; but this is denied by Dr Black.

285
Tin.

4. *Tin*. The combination of acetous acid with tin is so little known, that many have doubted whether distilled vinegar is capable of dissolving tin or not. Dr Lewis observes, "That plates of pure tin put into common vinegar begun in a few hours to be corroded, without the application of heat. By degrees a portion of the metal was taken up by the acid, but did not seem to be perfectly dissolved, the liquor appearing quite opaque and turbid, and depositing great part

286
Dr Lewis's experiments concerning the solubility of tin.

of the corroded tin to the bottom, in a whitish powder. **PRACTICE** A part of the tin, if not truly dissolved, is exquisitely divided in the liquor: for, after standing many days, and after passing through a filter, so much remained suspended as to give a whiteness and opacity to the fluid. Acid juices of fruits, substituted to the vinegar, exhibited the same phenomena. These experiments are not fully conclusive for the real solubility of tin in these acids, with regard to the purposes for which chemists have wanted such a solution: but they prove what is more important; that tin, or tinned vessels, however pure the tin be, will give a metallic impregnation to light vegetable acids suffered to stand in them for a few hours."

With regard to other metallic substances, neither the degree of attraction which the acetous acid has for them, nor the nature of the compounds formed by the union of it with such substances, are known; only, that as much of the reguline part of antimony is dissolved in this acid as to give it a violent emetic quality. See *Regulus of Antimony*.

Concentration of the Acetous Acid.

Common vinegar, as any other weak acid, may be advantageously concentrated by frost; as also may its spirit, or the distilled vinegar of the shops: but as the cold, in this country, is seldom or never so intense as to freeze vinegar, this method of concentration cannot be made use of here. If distilled vinegar be set in a water-bath, the most aqueous part will arise, and leave the more concentrated acid behind. This method, however, is tedious, and no great degree of concentration can be produced, even when the operation is carried to its utmost length. A much more concentrated acid may be obtained by distilling in a retort the crystals of copper, mentioned (nº 278) under the name of *disillid verdigresce*. A very strong acid may thus be obtained, which has a very pungent smell, almost as suffocating as volatile sulphureous acid. The count de Lauraguais discovered that this spirit, if heated in a wide-mouthed pan, would take fire on the contact of flaming substances, and burn entirely away, like spirit of wine, without any residuum. The same nobleman also observed, that this spirit, when well concentrated, easily crystallizes without addition.

287
Concentrated vinegar.

This may seem to be the most proper method of obtaining the acetous acid in its greatest degree of strength and purity; but as the process requires a very strong heat to be used towards the end of the operation, it is probable that part of the acetous acid may be by that means entirely decomposed. It would seem preferable, therefore, to decompose pure terra foliata tartari by means of the vitriolic acid, in the same manner as nitre or sea-salt are decomposed for obtaining their acids. In this case, indeed, the acetous acid might be a little mixed with the vitriolic; but that could easily be separated by a second distillation.

Dr Priestley, who gives us several experiments on the vegetable acid when reduced to the form of air, mentions his being easily able to expel it from some exceedingly strong concentrated vinegar, by means of heat alone. This seems somewhat contrary to the count de Lauraguais's observation of the distillation of

289
Dr Priestley's experiments.

PRACTICE the *spirit of verdigrease*, as it is commonly called, to crystallize; but a still greater difference is, that the vegetable acid air extinguished a candle, when, according to the count's observation, it ought to have been inflammable. The most curious property observed by Dr Priestley is, that the vegetable acid air being imbibed by oil olive, the oil was rendered less viscid, and clearer, *almost like an essential oil*. This is an useful hint; and, if pursued, might lead to important discoveries.

Acetous Acid combined with Inflammable Matter.

290
Vegetable
ether.

The only method yet known, of combining acetous acid with the principle of inflammability, is by mixing together equal parts of the strongly concentrated acid called *spirit of verdigrease*, and spirit of wine. The result is, a new kind of ether, similar to the vitriolic, nitrous, and marine. This ether, however, retains some of the acidity and peculiar smell of the vinegar. By rectification with fixed alkali, it may be freed from this acidity, and then smells more like true ether, but still retaining something of the smell, not of the acid, but the inflammable part of the vinegar.

In this process a greater quantity of ether is obtained than by employing the vitriolic acid; which shews that the vegetable acid is essentially fitter to produce ether than the vitriolic. This difference must undoubtedly be attributed to the great quantity of ardent spirit which enters into the composition of the acetous acid, and perhaps already approaches the state of ether.

VII. OF THE ACID OF TARTAR.

291
Tartar.

Tartar is a substance thrown off from wine, after it is put into casks to dehydrate. The more tartar that is separated, the more smooth and palatable the wine is. This substance forms a thick hard crust on the sides of the casks; and, as part of the fine dregs of the wine adhere to it, the tartar of the white wines is of a greyish white colour, called *white tartar*; and that of red wine has a red colour, and is called *red tartar*.

292
Cream of
tartar.

When separated from the casks on which it is formed, tartar is mixed with much heterogeneous matter, from which, for the purposes of medicine and chemistry, it requires to be purified. This purification is performed at Montpellier; and consists first in boiling the tartar in water, filtrating the solution, and allowing the salt to crystallize, which it very soon does; as tartar requires nearly twenty times its weight of water to dissolve it.

The crystals of tartar obtained by this operation are far from being perfectly pure; and therefore they are again boiled in water, with an addition of clay, which absorbs the colouring matter; and thus, on a second crystallization, a very pure and white salt is obtained. The crystals now obtained are called *cream*, or *crystals, of tartar*; and are commonly sold under these names.

To obtain the pure Acid of Tartar.

24 292
Scheele's analysis
of cream of
tartar.

For a long time the cream or crystals of tartar were considered as the purest acid which could be obtained from this substance; but, in the year 1770,

an analysis of tartar was published in the Swedish transactions, by Mr Scheele, a Swedish chemist. His method of decomposing the salt was, to dissolve it in a sufficient quantity of boiling water, then to add chalk in fine powder till the effervescence ceased. A copious precipitation ensued; and the remaining liquor being evaporated, afforded a soluble tartar. This proved, that cream of tartar is not, as was commonly supposed, an acid of a peculiar kind, joined with a great deal of earthy impurities; but really a compound salt, containing an alkali joined with an acid; and that the alkali produced from burnt tartar, is not generated in the fire, but pre-existent in the salt.

The whole sediment obtained in this experiment, is the calcareous earth combined with the acid of tartar, which may justly be called *selelenites tartareus*. (See n° 24). If some diluted vitriolic acid is poured upon this selelenites tartareus, the vitriolic acid expels the acid of tartar, forming a true selelenite with the earth, while the liquor contains the pure acid of tartar. By insipidation this acid may be made stronger, and even formed into small white crystals, which do not deliquesce in the air. A particular species of tartar extracted from sorrel hath been sold for taking spots out of cloths, under the name of *essential salt of lemons*.

293
Essential
salt of lemons.

This experiment was repeated by Dr Black; who farther observed, that if quicklime was used instead of chalk, the whole acid would be absorbed by the lime, and the remaining liquor, instead of being a solution of soluble tartar, would be a caustic lixivium.

Acid of tartar combined with Alkalies.

294
Soluble
tartar.

1. *Vegetable Alkali*. If the pure acid of tartar be combined with this alkali to the point of saturation, a neutral salt is produced, which deliquesces in the air, and is not easily crystallized, unless the liquor be kept warm, and likewise be somewhat alkaline. This salt, called *soluble tartar*, is used in medicine as a purgative; but as its deliquescence does not admit of its being kept in a crystalline form, it is always sold in powder. Hence, those who prepare soluble tartar, take no further trouble than merely to rub one part of fixed alkaline salt with three of cream of tartar, which renders the compound sufficiently neutral, and answers all the purposes of medicine.

295
Regenerated
cream of tartar.

According to Mr Scheele, cream of tartar may be recomposed from the pure acid and alkali, in the following manner: "Upon fixed vegetable alkali pour a solution of the acid of tartar. Continue this till the effervescence is over; the fluid will then be transparent; but if more of the acid is added, it will become turbid, and white, and small crystals like white sand will be formed in it. These crystals are a perfect cream of tartar."

Upon these principles, another method of decomposing cream of tartar might be tried; namely, adding to it as much oil of vitriol as would saturate the alkali, then dissolving and crystallizing the salt: but, by this method, there would be danger of the acid being adulterated with vitriolated tartar.

296
Scheette's
salt.

2. *Fossile Alkali*. The salt produced from an union of cream of tartar with fossile alkali, has been long known under the names of *Seignette's salt*, *sal Rupe*, *lenfis*, or *Roche's salt*; but as the cream of tartar is

now

PRACTICE now discovered to be not a pure acid, but adulterated with a portion of soluble tartar, possibly some differences might be observed if the pure acid was used.

This salt was first invented, and brought into vogue, by one Seignette, an apothecary at Rochelle, who kept the composition a secret as long as he could. Mess. Boulduc and Geoffroy afterwards discovered and published its composition.

To prepare this salt, crystals of mineral alkali are to be dissolved in hot water, and powdered cream of tartar thrown in as long as any effervescence arises. For the better crystallization of the salt, the alkali ought to prevail. The liquor must then be filtered and evaporated, and very fine large crystals may be obtained by cold, each of which is the half of a polygonous prism cut in the direction of its axis. This section, which forms a face much larger than the rest, is, like them, a regular rectangle, distinguishable from the others, not only by its breadth, but also by two distinct diagonal lines which intersect each other in the middle.

3. *Volatile Alkali.* With regard to this combination, all we know as yet, is, that if the alkali is over saturated with acid, a cream of tartar, almost as difficult of solution as that of fixed alkali, will be obtained.

Acid of Tartar combined with *Earths*.

All that is as yet known concerning these combinations, is, that with the calcareous earth a compound not easily soluble in water is formed. The other properties of this substance, and the nature of combinations of tartarous acid with other earths, are entirely unknown.

Acid of Tartar combined with *Metallic Substances*.

1. *Copper.* In its metallic state, cream of tartar acts but weakly on this metal, but dissolves verdigrise much more perfectly than distilled vinegar can. The solution with cream of tartar, being evaporated, does not crystallize, but runs into a gummy kind of matter; which, however, does not attract the moisture of the air. It readily dissolves in water, and makes a beautiful bluish green on paper, which has the property of always shining, as if covered with varnish. The effects of the pure acid on this metal have not yet been tried.

2. *Iron.* The effects of a combination of iron with the pure acid have not hitherto been tried. Cream of tartar dissolves this metal into a green liquor, which being evaporated runs *per deliquium*. It has been attempted to substitute a solution of this kind to the liquor used in printing calicoes formed of iron and four beer; but this gave a very dull brownish colour with madder. Possibly, if the pure acid was used, the colour might be improved. In medicine, a combination of cream of tartar with iron is used, and probably may be an useful chalybeate.

3. *Regulus of Antimony.* See Sect. III.

VIII. OF THE ACID OF SUGAR.

That sugar contains an acid, which on distillation by a strong fire arises in a liquid form, in common with that of most other vegetable substances, has been generally known; but how to obtain this acid in a concrete form, and to appearance as pure and crystal-

lizable as the acid of tartar, we were entirely ignorant, till the appearance of a treatise intitled, *Dijfer-tatio Chemica, de Acido Sacchari*, auctore Johanne Afzelio Arvidsson, 4^{to}, Upsalæ.

Of the method of procuring, and the properties of, this new acid, we have the following account in the Edinburgh Medical Commentaries, vol. iv.

"1. To an ounce of the finest white sugar in powder, in a retort with a neck, add three ounces of strong spirit of nitre.

"2. The solution being finished, and the phlogiston of the spirit of nitre mostly exhaled, let a receiver be properly fitted to the retort and luted, and the liquor then made to boil gently.

"3. When the solution has obtained a brownish colour, add three ounces more of spirit of nitre, and let the ebullition be continued till the fumes of the acid are almost gone.

"4. The liquor being at length emptied into a larger vessel, and exposed to a proper degree of cold, quadrangular prismatic crystals are observed to form; which being collected, and dried on soft paper, are found to weigh about 109 grains.

"5. The remaining liquor being again boiled in the same retort, with two ounces of fresh spirit of nitre, till the red vapours begin to disappear; and being then in the same manner exposed to crystallize, about 43 grains of saline spiculae are obtained.

"6. To the liquid that still remains, about two ounces more of spirit of nitre being added, and afterwards the whole being, both by boiling and evaporation, reduced to a dry mass, a brown, saline, gelatinous kind of substance is produced, which, when thoroughly dry, is found to weigh about half a drachm.

"In the same manner, a similar acid, we are told, may be obtained from different saccharine substances, as *gum-arabic*, *honey*, &c.; but from none in such quantities, or so pure, as from fine sugar."

This salt possesses some very singular properties, of which what appears to us the most remarkable, and which we cannot help reading with some degree of doubt, is, that it produces an effervescence on being added to such *alkaline, earthy, or metallic substances, as contain the vitriolic acid*. From this we should be apt to think, that this acid was capable of dissolving even the vitriolic acid from its basis.

Acid of sugar, being distilled in a retort, gives over about $\frac{1}{3}$ of its weight of water. By an intense heat it melts, and is partly sublimed; leaving in the retort a dark grey mass, of about the fifth part of the weight of the crystals made use of. The sublimed salt easily recovers its crystalline form, and seems to have undergone no further change by sublimation than being rendered more pure. During the distillation a great quantity of elastic vapour rushes out, (about 100 cubic inches from half an ounce of the crystals), which, from the distilled liquor's precipitating lime-water, we may judge to be fixed air. In a second sublimation, white fumes are sent over, which, when cold, appear to be an acid, glassy-coloured liquor, but cannot be again crystallized.

"Such parts of the salts as adhere to the sides and necks of the vessels, do not appear to be in the least changed in the process." (What these parts are, we do not comprehend). On a third sublimation, these

parts produced such elastic vapours as burst the receiver.

This singular salt has a considerable acid power; twenty grains of it giving a very considerable degree of acidity to a large tankard of water. It dissolves in an equal weight of distilled water, but concretes on the liquor's growing cool. It is also soluble in spirit of wine; 100 parts of boiling spirit of wine dissolving 56 of the saccharine crystals, but no more than 40 when cold. The solution in spirit of wine soon becomes turbid; and deposits a mucous sediment, in quantity about $\frac{2}{5}$ of the acid made use of. When cold, irregular scaly crystals are formed, which when dry are perfectly white.

334
Incredible
quantity of
volatile al-
kali saturat-
ed by it.

With vegetable alkali, the acid of sugar can scarcely be formed into crystals, unless either the alkali or acid predominate. With mineral alkali, a salt very difficult of solution is formed. The quantity of volatile alkali saturated by this acid is incredible. "Six parts of a pure volatile alkali (we suppose volatile salts are meant) may be saturated with one of the acid of sugar!" The produce is a quadrangular prismatic salt. With lime this acid unites so strongly, as to be separable by no other means than a strong heat. What kind of a salt results from this combination we are not told; but the author is of opinion, that this shews the use of lime in the purification of sugar, in order to absorb the superfluous acid. Being saturated with some of the *terra ponderosa*, the acid of sugar immediately deposits a quantity of pellucid angular crystals, scarcely soluble in water. With magnesia the salt appears in form of a white powder, soluble neither in water nor spirit of wine, unless the acid prevails. It has a stronger affinity with magnesia, than any of the alkaline salts. With earth of alum, no crystals are obtained; but a yellow pellucid mass, of a sweetish and somewhat astringent taste; which, in a moist air, liquefies, and increases two-thirds in weight.

This acid acts upon all metals, gold, silver, platinum, and quicksilver, not excepted, if they have been previously dissolved in an acid, and then precipitated. Iron in its metallic state is dissolved in very large quantity by the saccharine acid; 45 parts of iron being soluble in 55 of acid. By evaporation, the liquor shoots into yellow prismatic crystals, which are easily soluble in water. With cobalt, a quantity of yellow-coloured crystals are obtained, which being dissolved in water, and sea-salt added to the solution, form a sympathetic ink. The elective attractions of this singular acid are, first, Lime; then the *terra ponderosa*, magnesia, vegetable alkali, mineral alkali, and lastly clays. With spirit of wine an ether was obtained, which cannot easily be set on fire unless previously heated, and burns with a blue instead of a white flame.

335
Saccharine
ether.

336
Whether
this acid is
produced
from the ni-
trous.

Towards the conclusion of his dissertation the author observes, that some may imagine that the acid of nitre, made use of in these experiments, may have a considerable share in the production of what he has termed *acid of sugar*. But, though he acknowledges that this acid cannot in any way be obtained but by the assistance of spirit of nitre, he is thoroughly convinced that it does not, in any degree, enter into its composition.

What occurs to us on this subject is, that if the acid really pre-exists in the sugar, it must give some tokens of its existence by mixing the sugar with other substances besides spirit of nitre. The author himself thinks that lime acts upon the acid part of the sugar: from whence we are apt to conclude, that by mixing lime, in a certain proportion, with sugar, a compound should be obtained somewhat similar to what was formed by a direct combination of lime with the pure acid. In this case, we might conclude that the nitrous acid produces this salt, by combining with the inflammable part of the sugar, becoming thereby volatile, and flying entirely off, so as to leave the acid of the sugar pure. In the distillation of dulcified spirit of nitre, however, we have an instance of the nitrous acid itself being very much altered. This must therefore suggest a doubt, that the acid salt obtained in the present case is only the nitrous acid deprived of its phlogiston, and united with some earthy particles.

IX. OF THE ACID OF PHOSPHORUS.

This acid as yet is but little known. It is obtained in the greatest quantities from human urine, where it is combined with a volatile alkali, forming a singular kind of ammoniacal salts. It is there also found in combination with the vegetable fixed alkali; (see Sect. VI.) It may also be obtained from most vegetable substances, by distillation with a very violent heat; but in small quantity. When obtained in this manner, it combines with the phlogiston of the matter distilled, and assumes the form of phosphorus. As the only method of procuring this acid, without the trouble of a very tedious, and even dangerous, distillation, is by evaporation and crystallization, we shall here give the process for extracting the microcosmic salt from urine.

337
Phospho-
rine acid.

"A large quantity of urine is to be evaporated to the consistence of a thin syrup; which, being set in a cold place, will yield, in three or four weeks, foul brown-coloured crystals, which are the microcosmic salt, mixed with the marine, and other salts of urine. These crystals are to be dissolved in hot water; the solution filtered whilst it continues hot, and set to crystallize again; and the solution, filtration, and crystallization, repeated till the salt becomes pure and white. In all the crystallizations the microcosmic salt shoots first, and is easily distinguished and separated from the others. If the urine which remains after the first crystallization be further evaporated, and again set in the cold, it will yield more crystals; but browner and more impure than the former; and therefore requiring to be purified by themselves. From twenty gallons of urine, may be obtained four ounces of pure salt; a considerable part being still left in the residuum.

338
Microcos-
mic salt,
how procured.
red.

"In these operations the heat ought to be gentle, and the vessels either of glass or compact stone-ware. Urine being evaporated in a copper vessel, afforded only a green solution of that metal."

Concerning the nature of the microcosmic salt obtained by the above process, Mr Margraaff gives the following account in the Berlin Memoirs for 1746.

339
Mr Mar-
graaff's ex-
periments.

"Sixteen ounces of the salt, dissolved in a glass retort, in a heat gradually raised, gave over eight ounces of a volatile urinous spirit, resembling that from

PRACTICE from sal ammoniac by quicklime. The residuum was a porous brittle mass, weighing eight ounces. This, urged with a stronger fire in a crucible, bubbled and frothed much, and at length sunk down into the appearance of glass, without seeming to suffer any further diminution of its weight in the most vehement heat.

The vitreous matter dissolved in twice or thrice its quantity of water, into a clear, transparent, acid liquor, somewhat thick, not ill resembling in consistence concentrated oil of vitriol. This liquor totally corroded zinc into a white powder, which, being diluted with water, appeared in great part to dissolve, fixed alkalies occasioning a plentiful precipitation. It acted powerfully upon iron, with some effervescence; and changed the metal into a kind of muddy substance inclining to bluish, in part soluble in water like the preceding. It dissolved likewise a portion of regulus of antimony, and extracted a red tincture from cobalt. On lead and tin it had very little action. Copper it corroded but slightly. On bismuth, silver, and gold, it had no effect at all, either by strong digestion, or a boiling heat. Nor did the addition of a considerable portion of nitrous acid enable it to act upon gold.

“The vitreous salt in its dry form, melted with metallic bodies with a strong fire, acts upon them more powerfully. In each of the following experiments, two drachms of the salt were taken to two scruples of the metal reduced to small parts. (1.) Gold communicated a purple colour to the vitreous salt; on weighing the metal, however, its diminution was not considerable. (2.) Silver lost four grains, or $\frac{1}{10}$; and rendered the salt yellowish, and moderately opaque. (3.) Copper lost only two grains, or $\frac{1}{20}$, though the salt was tinged of a deep green colour. It seemed as if a portion of the salt had been retained by the metal, which, after the fusion, was found to be whiter and more brittle than before. (4.) During the fusion with iron, flashes like lightning were continually thrown out; a phosphorus being generated from the combination of the acid with the inflammable principle of the iron. Great part of the mixture rises up in froth; which, when cold, appears a vitreous scoria, covered on the surface with a kind of metallic skin, which, on being rubbed, changes its green colour to a yellowish. The rest of the iron remains at the bottom of the crucible, half melted, half vitrified, and spongy. (5.) Tin lost 18 grains, or nearly one-half its weight, and rendered the salt whitish; the remaining metal being at the same time remarkably changed. It was all over leafy and brilliant, very brittle, internally like zinc. Laid on burning coals, it first began to melt, then burnt like zinc, or phosphorus. (6.) Lead lost 16 grains, and gave the same whitish colour to the scoriae that tin does. The remaining lead was in like manner inflammable, but burnt less vehemently than the tin; from which it differed also in retaining its malleability. (7.) Mercury precipitated from aqua fortis, and well edulcorated, being treated with the salt in a glass retort, with a fire raised to the utmost, only 12 grains of mercury sublimed; 28 remaining united with the acid, in a whitish, semi-opaque mass. A solution of this, mixed in distilled water, deposited a quantity of a yellowish powder; which, by distillation

in a glass retort, was in great part revived into running mercury. A part also remained dissolved in the clear liquor; for a drop let fall on polished copper instantly whitened it. (8.) Regulus of antimony melted with the vitreous salt, lost eight or nine grains, (about $\frac{1}{2}$); the regulus assumed a fine, brilliant, striated appearance; the scoriae were somewhat opaque. (9.) Bismuth lost eight grains; the scoriae were like the preceding, but the bismuth itself suffered little change. (10.) Zinc, mixed with the salt, and distilled in a glass retort, yielded a true phosphorus, which arose in a very moderate heat. The residuum was of a grey colour, a little melted at the bottom, in weight not exceeding two drachms, so that two scruples had sublimed. This residuum, urged further in a small Hessian crucible, to perfect fusion, emitted an infinity of phosphoric flashes, with a kind of detonation. The matter, grown cold, looked like the scoriae of melted glass. (11.) White arsenic, mixed with this salt, separated in the fire, the greatest part of it subliming, and only so much remaining behind as increased the weight of the salt eight or nine grains. This compound appeared at first transparent; but, on being exposed to the air, became moist, and of an opaque whiteness, much resembling crystalline arsenic. (12.) Cinnabar totally sublimed; suffering no change itself, and occasioning none in the salt. Sulphur did the same. (13.) One part of the salt, mixed with ten of manganese, and melted in a close vessel, gave a semi-transparent mass, some parts of which were bluish. The crucible was lined with a fine purple glazing, and the edges of the mass itself appeared of the same colour.

“The vitreous salt dissolved also, in fusion, metallic calces, and carths. Chalk, with one third its weight of the salt, formed a semi-transparent vitreous mass: calcined marble, with the same proportion, flowed so thin as to run all through the crucible; gypsum, likewise, ran mostly through the crucible; what remained was semi-transparent. Lapis specularis ran entirely through the vessel. Spanish chalk gave a semi-transparent mass, which sparkled on breaking; and fine white clay, a similar one. Saxon topaz and flint were changed into beautiful opal-coloured masses; the earth of alum into a semi-transparent mass, and quick lime into an opaque white one. The mass with flints imbibed moisture from the air; the others not.

“Oil of vitriol, poured upon one fourth its weight of this salt in a retort, raised an effervescence, acquired a brownish colour, and afterwards became turbid and white. On raising the fire, the oil of vitriol distilled, and the matter in the bottom of the retort melted. In the neck was found a little sublimate, which grew moist in the air; as did likewise the remaining salt, which was opaque and whitish. Concentrated spirit of nitre, distilled with this salt in the above proportion, came over unchanged; no sublimate appeared; the residuum looked like glass of borax. The distilled spirit did not act in the least upon gold, even by coction. Strong spirit of sea-salt being distilled in the same manner, no sensible change was made either in the spirit or the salt.

“Equal parts of the vitrified microcosmic salt and salt of tartar being urged with the strongest fire that a glass retort could bear, nothing sensible came over,

PRACTICE nor did the mixture appear in thin fusion. Dissolved in water, filtered, and duly evaporated, it afforded, very difficultly, oblong crystals, somewhat alkaline; the quantity of alkali having been more than enough to saturate the acid. A whitish matter remained on the filter, amounting to seven or eight grains, from two drachms of the mixture; this, after being washed and dried, melted before a blow-pipe, as did likewise the crystals.

310
Expels the
acids of vi-
triolated
tartar, nitre
and sea-salt.

“ This salt seems to extricate, in part, the acids of vitriolated tartar, nitre, and sea-salt. (1.) On distilling a mixture of it with an equal quantity of vitriolated tartar, there came over some ponderous acid drops, which, saturated with fixed alkali, formed a neutral salt greatly resembling the vitriolated tartar. The residuum readily dissolved in water, and difficultly crystallized. (2.) Nitre, treated with the same proportion of the salt, began to emit red vapours. The residuum was of a peach-blossom colour, appeared to have melted less perfectly than the preceding, and dissolved more difficultly in water. The solution deposited a little earthy matter; and, on being slowly evaporated, shot into crystals, which did not deliquesce in the fire. (3.) Sea-salt, distilled in the same manner, manifestly parted with its acid; the residuum was whitish, readily dissolved in water, and afforded some cubical crystals. (4.) Sal ammoniac suffered no change. (5.) Borax, with an equal quantity of vitreous salt, run all through the crucibles.

“ Solutions of this salt precipitated the earthy part of lime-water, of solution of alum, of flint dissolved in fixed alkali, and the combination of marine acid with chalk or quicklime. The precipitate from this last liquor is tenacious like glue, and does not dissolve even in boiling water; exposed to a strong fire, it froths prodigiously, and at last melts into a thick scoria.

“ Solutions of this salt precipitate also sundry metallic solutions; as butter of antimony, solution of silver, copper, lead, iron, mercury, and bismuth, in the nitrous acid; and of tin in aqua regis. The precipitate of iron from spirit of salt is a tenacious mass; that of silver from aqua fortis, sometimes a white powder, sometimes tenacious. Copper from aqua fortis is sometimes thrown down in form of a white powder, and sometimes in that of a green oil, according to the proportions and diluteness of the liquor. Silver is not precipitated at all by this acid from its solution in vinegar, nor gold from aqua regis.

“ An ounce of the vitreous salt, well mixed with half an ounce of foot, and committed to distillation, yielded a drachm of fine phosphorus. The black residuum, being elixated with boiling water, and the liquor passed through a filter, there remained upon the filter eight scruples of a black matter; and, on evaporating and crystallizing the liquor, about seven drachms were obtained of oblong crystals, which did not deliquesce in a moist air, but became powdery in a warm one. These crystals, treated afresh with inflammable matter, yielded no phosphorus. Before a blow-pipe they melted into a transparent globular mass, which, on cooling, became turbid and opaque. Dissolved in water, they precipitated solutions of silver, mercury, copper, and of chalk; though they did not act upon the latter so powerfully, nor produce with it

a gluey mass, as before they had been deprived of PRACTICE their phosphorine acid.”

On this account of the phosphorine, or rather microcosmic, acid, which we have taken from Lewis's notes on Neuman's chemistry, we have only to observe, that the microcosmic salt either contains two distinct acids, one of which only is capable of being united with inflammable matter so as to produce phosphorus; or that the true phosphorine acid itself is capable of a kind of decomposition, by which it may be made incapable of uniting any more with phlogiston. It would seem likewise, that some substances are much more proper for producing phosphorus than others; and that those which contain the greatest quantity of inflammable matter are not the most proper. Thus, half an ounce of foot mixed with a whole ounce of acid, yielded only a *drachm* of phosphorus; while two drachms of acid, with no more than two scruples of zinc, gave two scruples of phosphorus; nor did the distillation seem to be finished.

X. Of the Acid of ANTS.

The acid may be obtained from these insects either by distillation, or simple infusion in water. From red, twenty-four ounces of ants, Neuman obtained eleven ounces and an half of acid as strong as good vinegar, by distillation in *balneo marie*. Of this acid, Mr Margraaf gives the following account in the Berlin Memoirs for 1749.

“ The acid of ants effervesces with alkaline salts, both fixed and volatile. With volatile alkalies it forms a neutral liquor, which, like that composed of the same alkalies and vinegar, yields no concrete salt on distillation. With fixed alkalies it concretes, upon proper exhalation into oblong crystals, which deliquesce in the air. The crystals, or the saturated neutral liquor uncrystallized, on being distilled with a fire increased till the retort begun to melt, yielded a liquor scarce sensibly acid, and afterwards a small quantity of an urinous and partly ammoniacal liquor. The remaining black matter, dissolved in distilled water, filtered and evaporated, shot into large crystals which did not deliquesce in the air, though they were in taste strongly alkaline, effervesced with acids, and had all the other properties by which fixed alkalies are distinguished.

“ This acid dissolves, with great effervescence, coral, chalk, and quicklime; and concretes with them all into crystals which do deliquesce in the air.

“ It does not precipitate silver, lead, or mercury, from the nitrous acid; nor quicklime from the marine. Hence it appears to have no analogy to the marine or vitriolic acids; the first of which constantly precipitates the metallic solutions, and the other the earthy.

“ It does not act upon filings of silver; but (like vegetable acids), it totally dissolves, by the assistance of heat, the calx of silver precipitated from aqua fortis by salt of tartar.

“ It does not dissolve calces of mercury, (as vegetable acids do); but revives them into running quicksilver.

“ It acts very weakly upon filings of copper; but perfectly dissolves copper that has been calcined. The solution yields beautiful, compact, green crystals.

“ It

PRACTICE

PRACTICE

"It dissolves iron-filings with violence; the solution, duly evaporated, shoots into crystals more readily than that made in distilled vinegar. It scarcely acts at all upon filings of tin.

"It does not, according to Mr Margraff, corrode filings of lead; but dissolves, by the assistance of heat, the red calx of lead. The solution crystallizes into a saccharum saturni. In Mr Ray's philosophical letters, it is said, that "lead put into the acid spirit, or fair water, together with the animals themselves, makes a good *saccharum saturni*;" and that this saccharum, on being distilled, "will afford the same acid spirit again, which the saccharum saturni made with vinegar will not do, but returns an inflammable oil with water, but nothing that is acid; and saccharum saturni made with spirit of verdigrease doth the same in this respect with spirit of pismires.

"It dissolves zinc with vehemence, and shoots, upon due evaporation, into inelegant crystals, not at all like those produced with distilled vinegar. On bismuth, or regulus of antimony, it has little effect, either when calcined, or in their metalline state."

XI. Of the ACID of AMBER.

The nature of this acid is as yet but little known, and Mr Pott is the only chemist who seems to have examined it with accuracy. We shall therefore give an abstract of the principal observations and experiments he has made on this salt.

"Salt of amber requires a large quantity of water for its solution. In the first crystallization (being much impregnated with the oil, which rises from the amber along with it), it shoots into spongy flakes, in colour resembling brown sugar-candy; the crystals which succeed prove darker and darker coloured. On repeating the depuration, the crystals appear at top of a clear yellow, or whitish colour, in form of long needles or feathers; at bottom, darker, and more irregular, as are likewise the crystals which shoot afterwards. The crystals neither easily nor become powdery in the air: rubbed, they emit a pungent smell like that of radishes, especially if warmed a little; their taste is acid, not in the least corrosive, but with a kind of oily pungency.

"This salt, kept in the heat of boiling water, loses nothing of its weight, and suffers no alteration. In a great heat it melts like oil; after which a little oily acid arises, then oily striz appear in the lower part of the retort, and the salt sublimates into the neck, partly in the form of a dark yellow butter, and partly in that of feathers, a black coaly matter remaining at bottom; so that, by this process, a part of the salt is destroyed.

"Oil of turpentine has no action on this salt. Highly rectified spirit of wine gains from it a yellow colour in the cold; and, on the application of heat, dissolves a considerable quantity, but deposits great part of it on cooling. The salt thus deposited is somewhat whiter than before, but still continues sensibly yellow. The dulcified spirit of fal ammoniac dissolves it readily, without effervescence, into a yellow liquor; if the salt was foul, the solution proves of a red colour; on burning of the vinous spirit, a neutral liquor remains.

"A solution of salt of amber in water, saturated

with a pure alkaline lixivium, yielded, on inspissation, a saline matter, which would not crystallize, and which, when excicated by heat, deliquescent in the air, leaving a considerable proportion of an earthy, unctuous matter. Being again gently inspissated, it left a brownish salt, very soluble, weighing one half more than the salt of amber employed. This salt effervesced with the vitriolic and nitrous acids: the vapour, which exhaled, was not acid, but oily and sulphureous. On repeating the experiment, and fully saturating the alkali with the salt of amber, the neutral salt made no effervescence with these acids. This salt did not perfectly melt before a blow-pipe; continued in the fire for some time, it effervesced with aqua fortis. In distillation it yielded a bitter, oily, alkalescent spirit, much resembling the spirit of tartar; and towards the end, an empyreumatic oil. The residuum elixated, yielded the alkaline salt again of a brown colour.

"Salt of amber effervesces strongly with volatile alkalies; and, on saturation, forms with them an oily ammoniacal liquor, which, in distillation, totally arises in a fluid form, except that a small portion of a penetrating, oily, saline matter concretes towards the end.

"On distilling salt of amber with an equal quantity of common fal ammoniac, an acid marine spirit came over, of a strong smell, and a brown colour: afterwards, a little white fal ammoniac sublimed; at length arose suddenly a large quantity of a fuliginous or bituminous matter, leaving behind a small portion of a like shining black substance. The coaly matter was considerably more in quantity than the salt of amber employed. On treating it with nitre, red vapours arose, and the mixture detonated with violence. A mixture of it with borax, frothed and swelled up much more than borax by itself; and, on raising the fire, yielded only some oily drops; the acid being destroyed by this salt, as by fixed alkalies and quicklime.

"Spirit of sea-salt, poured upon one-fourth its weight of salt of amber, made scarce any solution in the cold: on the application of heat, nearly the whole coagulated into the consistence of a jelly. In distillation, the spirit of salt arose first; then almost the whole of the salt of amber, partly like firm butter, partly like long striated plumous alum, very pure, and of a fine white colour, its oily matter being changed into a coal at the bottom. The salt, thus purified, makes no precipitation in the solution of silver, and consequently retains nothing of the marine acid; nor does it precipitate solution of quicklime made in spirit of salt, and consequently contains nothing vitriolic. If any of the mineral acids was contained in this salt, it could not here escape discovery; the oil, which in the rough salt is supposed to conceal the acid, being in this process separated.

"Aqua fortis being poured upon one-fourth its weight of salt of amber, extracted a yellowish colour from it in the cold, but dissolved little: on the application of heat, the whole dissolves into a clear liquor, without any coagulation: if the salt is very oily, the solution proves red. In distillation, greatest part arises in a liquid form, with only a very small quantity of concrete salt. The spirit does not act upon gold,

PRACTICE but dissolves silver, and quicksilver, as at first; a proof that it has received no marine acid from the salt of amber.

"Oil of vitriol being added to twice its weight of salt of amber diluted with a little water, a moderate fire elevated an acidulous liquor, which appeared to proceed from the salt of amber; for its making no change in solution of fixed salt ammoniac, shewed it not to be vitriolic. On continuing the distillation by a stronger fire, greatest part of the salt arises undestroyed, and the oil of vitriol along with it; a black, light, porous earth remaining.

"Equal parts of quicklime and salt of amber gave over in distillation only an acidulous phlegm; the residuum, elixated with water, yielded a solution of the lime in the acid of amber, resembling a solution of the same earth in vegetable acids, precipitable by alkaline salts, and by the vitriolic acid. Lime added to a watery solution of salt of amber, dissolves with some effervescence; after which, the whole coagulates into the consistence of a jelly: this, diluted with water, proves similar to the foregoing solution.

"Solution of salt of amber makes no precipitation in solutions of silver or quicksilver. It dissolves zinc, as all acids do: fixed alkalies precipitate the zinc: the volatile do not; and when a sufficient quantity of the volatile has been added, the fixed make no precipitation. It acts exceeding slowly and difficultly upon copper; but corrodes calcined copper in a shorter time. It soon corrodes iron, by coction, into a crocus, and dissolves a part into a liquid form: the solution has little colour; but alkaline salts readily discover that it holds iron, by rendering it turbid and whitish, and throwing down a considerable quantity of a greenish calx."

XII. Of Fixed ALKALINE SALTS.

316
How procured. Of these there are two kinds; the vegetable, and mineral, (see n° 23.) The first is never found by itself, and but rarely in combination with any acid; but is always prepared from the ashes of burnt vegetables. The second is found native in some parts of the earth. It is likewise found, in very large quantities, combined with the marine acid, in the waters of the ocean, and in the bowels of the earth; thus forming the common alimentary salt. It is also produced from the ashes of certain sea-plants, and of the plant called *kali*; from whence both the mineral and vegetable alkalies have taken their name.

317
Vegetable alkali crystallized. The vegetable alkali difficultly assumes a crystalline form; nevertheless, it may be partially united with some acids in such a manner as to crystallize, and lose its property of deliquating in the air, without, at the same time, ceasing to be an alkali. Of this we have an example in the acid of ants above mentioned. Something of the same kind we have observed in treating vegetable fixed alkali with spirit of wine. A gallon of pretty strong spirit of wine being drawn over from a pound of salt of tartar, a black unctuous liquor was left, which shot into crystals very much resembling vitriolated tartar, and which did not deliquesce in the air, but were nevertheless strongly alkaline.

The mineral alkali in its natural state always assumes a crystalline form, somewhat resembling that of sal mirabile. It does not deliquesce in the air, nor does it

seem to have so strong an attraction for water, even when in its most caustic state, as the vegetable alkali; hence mineral alkali is preferable to it in making soap, which is always of a firmer consistence with mineral than with vegetable alkali. If vegetable alkali is combined with spirit of salt, some change seems to be thereby induced upon it; as the salt produced by expelling the marine acid by means of the vitriolic, and then crystallizing the mals, crystallizes differently from vitriolated tartar. Whether the vegetable alkali might by this means be entirely converted into the mineral, deserves a further inquiry.

Both vegetable and mineral alkalies, when applied to the tongue, have a very sharp, pungent, and urinous taste; but the vegetable considerably more so than the mineral. They both unite with acids, and form different neutral salts with them: but the vegetable alkali seems to have rather a greater attraction for acids than the other; although this difference is not so great, as that a neutral salt, formed by the union of mineral alkali with any acid, can be decomposed by an addition of the vegetable alkali.

Both vegetable and mineral alkali appear to be composed of an exceedingly caustic salt united with a certain quantity of fixed air: (See AIR, n° 10.) This may be increased so far, as to make the vegetable alkali assume a crystalline form and lose great part of its alkaline properties; but as the adhesion of great part of this air is very slight, it easily separates by a gentle heat. Some part, however, is obstinately retained; and the alkali cannot be deprived of it by the most violent calcination *per se*. The only method of depriving it entirely of its fixed air, is by mixing an alkaline solution with quicklime.

Fixed Alkalies combined with Sulphur.

The produce of this is the red fetid compound called *hepar sulphuris*, or liver of sulphur. It may be made by melting sulphur with a gentle heat, and stirring into it, while melted, four times its weight of dry alkaline salt. The whole readily melts and forms a red mass of a very fetid smell, and which deliquesces in the air. If sulphur is boiled in a solution of fixed alkaline salt, a like combination will take place.

In this process, when the *hepar* is made either in the dry or the moist way, the fixed air of the alkali is discharged, according to Dr Priestley's observation. Neither does a fixed alkali, when combined with fixed air, seem capable of uniting with sulphur; nor will the union be accomplished without heat, unless the alkali is already in a caustic state. Hence a cold solution of *hepar sulphuris* may be decomposed, partly at least, by fixed air. On adding an acid, however, the decomposition takes place much more rapidly; and the sulphur is precipitated to the bottom, in form of a white powder.

During the precipitation of the sulphur from an alkali, by means of acids, a thick white smoke arises, of a most fetid smell, and suffocating nature; this smoke seems to approach more nearly to the nature of pure phlogiston, than any substance that hath been hitherto observed. It burns quietly, without explosion, on a candle's being held in it. Calces of silver, lead, iron, or bismuth, are rendered black by it. Hence, if any thing

Decomposed.

PRACTICE thing is wrote with a solution of lead, and a solution of hepar sulphuris is passed over it when dry, the writing, formerly invisible, will immediately appear of a blackish brown colour. Silver, in its metallic state, is prodigiously blackened either by the contact of this vapour, or by being immersed in a solution of the hepar sulphuris itself. Litharge is instantly re-flored to its metallic state, on being immersed even in a cold solution of hepar sulphuris.

323 Inflammable vapour in the decomposition of it.
324 Phlogiston of sulphur disposed to quit the acid.
By being united with an alkali, the acid of sulphur seems very much disposed to quit the phlogiston. If a solution of hepar sulphur is exposed to the air for some time, it is spontaneously decomposed; the phlogiston of the sulphur flying off, and the acid remaining united with the alkali into a vitriolated tartar. This decomposition takes place so remarkably, when liver of sulphur is dissolved in water, that, by a single evaporation to dryness, it will be almost totally changed into vitriolated tartar. If this substance, in a dry state, be exposed to a moderate degree of heat, and the mass kept constantly stirring, a like decomposition will follow; the phlogiston of the sulphur will fly off, and the acid unite with the alkali.

325 Metals and charcoal dissolved by it.
Liver of sulphur is a great solvent of metallic matters; all of which, except zinc, it attacks, particularly in fusion. It seems to dissolve gold more effectually than other metals; (see Sect. III.) This compound also dissolves vegetable coals, even by the humid way; and these solutions, if suffered to stand in the open air, always precipitate a black powder, no other than the coal they had dissolved, in proportion to the quantity of hepar sulphuris decomposed. When vegetable coal is thus dissolved by liver of sulphur in fusion, it is of a much deeper red than in its natural state. The solution in water is of a green colour.

Fixed Alkalies combined with *Expressed Oils*.

326 Soap.
The result of this combination is *soap*; for the preparation of which in large quantities in the way of trade, see SOAP. The soap which is used in medicine, is prepared without heat, in the following manner, according to the author of the Chemical Dictionary.

"One part of quicklime, and two parts of good "Spanish soda" (the salt prepared from the ashes of the herb kali), "are boiled together during a short time "in an iron caldron. This lixivium is to be filtered, "and evaporated by heat, till a vial, capable of containing an ounce of water, shall contain an ounce "and 216 grains of this lixivium. One part of this "lixivium is to be mixed with two parts of oil of "olives, or of sweet almonds, in a glass or stone-ware vessel. The mixture soon becomes thick and "white; and must be stirred from time to time with "an iron spatula. The combination is gradually completed, and in seven or eight days a very white "and firm soap is obtained."

In attempting combinations of this kind, it is absolutely necessary that the alkali be deprived of its fixed air as much as possible; otherwise the soap will be quite unctuous and soft: for fixed alkalies have a greater attraction for fixed air than for oil, and hence soap is decomposed by blowing fixed air into a solution of it in water.

Fixed Alkalies combined with *Essential Oils*.

The volatility of these oils in a great measure hinders them from being acted upon by alkalies: nevertheless combinations of this kind have been attempted; and the compounds so produced have been called *Starkey's soap*, from one Starkey a chemist who endeavoured to volatilize salt of tartar by combining it with oil of turpentine. His method was, to put dry salt of tartar into a matras, and pour upon it essential oil of turpentine to the height of two or three fingers breadth. In five or six months, a part of the alkali and oil were combined into a white saponaceous compound. This must be separated from the mixture, and more of it will afterwards be formed by the same method.

Chemists, imagining this soap to be possessed of considerable medical virtues, have endeavoured by various methods to shorten this tedious process. Of these one of the most expeditious is that recommended by Mr Beaumé; which consists in triturating, for a long time, alkaline salt upon a porphyry, and adding oil of turpentine during the trituration. According to him, the thick resinous part of the oil only can combine with the salt; and, during the time this combination is effected, the more subtle and attenuated parts will fly off. Hence he finds, that the operation is considerably abridged by the addition of a little turpentine, or common soap. The most expeditious of all, however, is that mentioned by Dr Lewis; which consists in heating the alkali red hot, and then throwing it into oil of turpentine, stirring them well together; on which they immediately unite into a saponaceous mass.

This kind of soap is subject to great alterations from keeping; particularly the loss of its colour, and a kind of decomposition occasioned by the extraction of an acid from the oil of turpentine, which unites with the alkali, and crystallizes not only all over the surface, but in the very substance of the soap. The nature of this salt is unknown, but certainly deserves consideration.

Fixed Alkalies combined with *Phlogiston*.

This combination is effected by calcining them with the charcoal either of vegetable or animal matters. The consequence is, that they are greatly altered in their properties; sometimes so much, as to be unable to precipitate calcareous earths from their solutions in acids. Metallic solutions precipitated by them in this state, assume different colours. (See Sect. III. *Iron*.)

Differences observed between Fixed Alkalies obtained from different *Vegetables*.

These differences we must conceive to arise from some proportion of the oily and phlogistic matter of the vegetable remaining in the ashes from whence the salts are extracted; for when reduced to their utmost purity, by repeated calcinations in a strong fire, and deliquiations in the air, all of them, the marine alkali excepted, appear to be the very same.

On this subject Mr Gmelin has given a great number of experiments in the fifth volume of the *Commentaria Petropolitana*; and found very considerable differences, not only between the alkaline salts, but likewise

PRACTICE

327 Starkey's soap.

328 Mr Gmelin's experiments.

PRACTICE

likewise the pure vegetable earths obtained from different vegetables by burning. (See Sect. II. *Vegetable Earths*.) The salts of the several plants examined were prepared with great care, and all of them exactly in the same manner; each vegetable being burnt in a separate crucible, with the same degree of fire, till no remains of coaly matter could any longer be perceived; and the ashes elixated in glass vessels with cold distilled water. The salts, thus obtained, were found to produce different colours, on mixture with certain liquors; and to effervesce in very different degrees with acids: certain metallic solutions were by some precipitated, by others only rendered thicker, by others both precipitated and rendered thick; whilst some occasioned neither the one nor the other of these changes, but left the fluid clear and transparent. Thus, with the vitriolic acid, the salts of southernwood and sage struck a pale brown colour; those of pine-tops and rue, a yellow; that of fern, a reddish yellow; and that of fennel, a dark leek-green: that of dill yielded a leek-green precipitate, with elegant green flakes floating in the liquor. This last salt also gave a greenish precipitate with the marine acid, and a red one with the nitrous. Solution of corrosive sublimate was changed yellow by salt of southernwood; of a brownish colour, by that of colts-foot; of a deep red, by that of wormwood; and of a pitch colour, by that of dill. That of fern threw down an opal-colour; of fige, a sulphur-yellow; of elder flowers, a citron-yellow; of fennel, a saffron-colour; and of milfoil a deep-red precipitate. From solution of silver, salt of *carduus benedictus* threw down a white; of camomile, a grey; of hyssop, a brownish; of dill, a blackish brown; of scabrous, a yellowish; and that of pine-tree tops, a sulphur-yellow precipitate. Solution of vitriol of copper was changed by salt of southernwood to a bright sea-green, by that of dill to an unsightly-green, of agrimony to a greenish-blue, and by that of milfoil to a bright sky-blue: the salt of penny-royal made the liquor thick as well as blue, and that of feverfew made it thick and green: the salt of hyssop threw down a green precipitate, that of scurvy-grass a blue one, and that of fumitory a greenish-blue; whilst the salt of fern made scarcely any change either in the colour or consistency of the liquor.

XIII. OF VOLATILE ALKALI.

This is a kind of salt obtained from all animal, some vegetable substances, and from soot, by distillation with a strong heat; and from all vegetable substances by putrefaction. Though a volatile alkali is procurable from all putrid animal substances by distillation, yet the putrefactive process does not seem to prepare volatile alkali in all of these. Putrid urine, indeed, contains a great quantity of alkali ready formed, whence its use in scouring, &c. but the case is not so with putrid blood or flesh. These afford no alkali till after the phlegm has arisen; and this they would do, though they had not been putrefied.

Volatile alkali, when pure, appears of a snowy whiteness; has a very pungent smell, without any disagreeable empyreuma; is very easily evaporable, without leaving any residuum; effervesces with acids much more strongly than fixed alkali; and forms with them

neutral compounds called *ammoniacal salts*, which we have already described, and which are different according to the nature of the acid made use of; for all volatile alkalis, when perfectly purified, appear to be the very same, without the smallest difference.

Like fixed alkalis, these salts contain a great quantity of fixed air, on which their solidity depends; and which may be so increased as perfectly to neutralize, and deprive them of their peculiar taste and smell. When neutralized by fixed air, they have a very agreeable pungent taste, somewhat resembling that of weak fermenting liquors. When totally deprived of fixed air, by means of lime, they cannot be reduced to a solid form; but are dissipated in an invisible and exceedingly pungent vapour, called by Dr Priestley *alkaline air*. When volatile alkaline salt is dissolved in water, the solution is called a *volatile alkaline spirit*.

Distillation and Purification of Volatile Alkalies.

The materials most commonly used for preparing volatile alkalis are the solid parts of animals, as bones, horns, &c. These are to be put into an iron pot of the shape recommended for solution; (see no 68). To this must be fitted a flat head having a hole in the middle, about two inches diameter. From this a tube of plate-iron must issue, which is to be bent in such a manner, that the extremity of it may enter an oil-jar, through an hole made in its upper part, and dip about half an inch under some water placed in the lower part. The mouth of the jar is to be fitted with a cover, luted on very exactly; and having a small hole, which may be occasionally stopped with a wooden peg. The junctures are to be all luted as close as possible, with a mixture of clay, sand, and some oil; and those which are not exposed to a burning heat, may be further secured by quicklime and the white of an egg, or by means of glue. A fire being now kindled, the air contained in the distilling vessel is first expelled, which is known by the bubbling of the water; and to this vent must be given by pulling out the wooden peg. A considerable quantity of phlegm will then come over, along with some volatile alkali, a great quantity of fixable air, and some oil. The alkali will unite with the water, and likewise some part of the fixed air, the oil swimming above. A great many incoercible vapours, however, will come over, to which vent must be given from time to time, by pulling out the peg. The distillation is to be continued till all is come over; which may be known by the cessation, or very slow bubbling of the water. The iron-pipe must then be separated from the cover of the distilling vessel, lest the liquid in the jar should return into it, on the air being condensed by its cooling. In the jar will be a volatile spirit, more or less strong according as there was less or more water put in, with an exceedingly fetid black oil floating upon it.

The rectification of the volatile alkali is most commodiously performed at once by combining it with an acid; and, as spirit of salt has the least affinity with inflammable matter, it is to be chosen for this purpose, in preference to the vitriolic, or nitrous. As the spirit is excessively oily, though already much weakened by the admixture of the water in the jar, if a very large quantity was not originally put in, an equal

319
Whence
obtained.

320
Rectifica-
tion.

equal quantity of water may still be added, on drawing off the spirit. That as little may be lost as possible, the spirit should be received in a stone bottle; and the marine acid, likewise in a distilled state, added by little and little, till the effervescence ceases. The liquor, which is now an impure solution of sal ammoniac, is to be left for some time, that the oil may separate itself; it is then to be filtered, evaporated, and crystallized in a leaden vessel. If the crystals are not sufficiently pure at the first, they will easily become so on a second dissolution.

331
Volatile sal ammoniac.

From sal ammoniac thus obtained pure, the vitriolic alkali may be extricated by distillation with chalk, alkaline salts, or quicklime. Alkaline salts act more briskly than chalk, and give a much stronger volatile alkali. The strength of this, however, we know, may be altered at pleasure, by adding to, or depriving it of, its natural quantity of fixed air. Hence, perhaps, the best method would be, to prepare volatile alkalies altogether in a fluid state, by means of quicklime; and then add fixed air to them, by means of an apparatus similar to that directed by Dr Priestley for impregnating water with fixed air.

332
Cuprum ammoniacale.

Volatile Alkalies combined with Metals.

There are only three metals, *viz.* copper, iron, and lead, upon which, while in their metallic form, volatile alkalies are capable of acting. Copper-salts are dissolved by volatile alkali, especially in their caustic state, into a liquor of a most admirable blue colour. It is remarkable, that this colour depends entirely upon the air having access to this solution: for if the bottle containing it is close stopp'd, the liquor becomes colourless; but, however, resumes its blue colour, on being exposed to the air. On evaporation, a blue saline mass is obtained, which, mixed with fats, or other inflammable matters, tinges their flame green, leaving a red calx of copper, soluble again in volatile spirits as at first. This saline substance has been received into the last edition of the Edinburgh Dispensatory, under the name of *cuprum ammoniacale*, as an antiepileptic.

333
Copper, fulminating.

The blue mixture of solution of copper in aqua fortis with volatile spirits, yields sapphire-coloured crystals, which dissolve in spirit of wine, and impart their colour to it. If, instead of crystallization, the liquor be totally evaporated, the remaining dry matter explodes, in a moderate heat, like aurum fulminans. This is given as a fact by Dr Lewis; but hath not succeeded upon trial by Dr Black.

On the other two metals, the action of volatile alkali is by no means so evident: it dissolves iron very slowly into a liquor, the nature of which is not known; and lead is corroded by it into a mucilaginous substance.

Volatile Alkalies combined with Inflammable Substances.

With expressed oils, the caustic volatile alkali unites into a soft unctuous mass, of a very white colour, imperfectly soluble in water; and which is soon decomposed spontaneously. Compositions of this kind are frequently used for removing pains, and sometimes with success. With essential oils, volatile alkalies may be united, either in their dry or liquid form, by means of distillation. The produce is called *sal volatile ole-*

334
Sal volatile oleosum.

osum; it is much more frequently used in a liquid than in a dry form. The general method of preparation is by distilling volatile alkali along with essential oils and spirit of wine, or the aromatic substances from whence the essential oils are drawn. These compositions are variable at pleasure; but certain forms are laid down in the dispensaries, with which it is expected that all the chemists should comply in the preparation of these medicines.

Eau de Luce.

This is the name given to an exceedingly volatile spirit, which some years ago was pretty much in vogue; and indeed seems very well calculated to answer all the purposes for which volatile alkalies can be useful. It was of a thick white colour, and smelled somewhat of oil of amber. A receipt appeared in Lewis's dispensatory for the preparation of this fluid, under the name of *spiritus volatilis succinatus*. The method there directed, however, did not succeed; because though the alkaline spirit is capable of keeping a small quantity of oil of amber suspended, the colour is greatly more dilute than that of genuine eau de luce. In the Chemical Dictionary we have the following receipt: "Take four ounces of rectified spirit of wine, and in it dissolve 10 or 12 grains of white soap; filter this solution; then dissolve in it a drachm of rectified oil of amber, and filter again. Mix as much of this solution with the strongest volatile spirit of sal ammoniac, as will be sufficient, when thoroughly shook, to give it a beautiful milky appearance. If upon its surface be formed a cream, some more of the oily spirit must be added."

335
Spiritus volatilis succinatus.

This receipt likewise seems insufficient. For the oil of amber does not dissolve in spirit of wine: neither is it probable that the small quantity of soap made use of could be of any service; for the soap would dissolve perfectly in the alkaline spirit, without suffering any decomposition. The only method which we have found to answer is the following. Take an ounce, or any quantity at pleasure, of balsamum Canadense; place it in a small china basin, in a pan of boiling water, and keep it there till a drop of it taken out appears of a resinous consistence when cold. Extract a tincture from this resin with good spirit of wine; and having impregnated your volatile spirit with oil of amber, lavender, or any other essential oil; drop in as much of the spiritous tincture as will give it the desired colour. If the volatile spirit is very strong, the eau de luce will be thick and white, like the cream of new milk; nor is it subject to turn brown with keeping.

Volatile Tincture of Sulphur.

This is a combination of the caustic volatile alkali, or spirit of sal ammoniac, with quicklime. It is usually directed to be made by grinding lime with the sulphur, and afterwards with the sal ammoniac, and distilling the whole in a retort; but the produce is by this method very small, and even the success uncertain. A preferable method seems to be, to impregnate the strongest caustic volatile spirit with the vapour which arises in the decomposition of hepatic sulphur by means of an acid, in the same manner as directed for impregnating water with fixed air. See AIR, n° 49.

This

PRACTICE

336
Sympathe-
tic ink.

This preparation has a most nauseous fetid smell, which spreads to a considerable distance; and the effluvia will blacken silver or copper, if barely placed in the neighbourhood of the unstopped bottle. This property renders it capable of forming a curious kind of sympathetic ink; for if paper is wrote upon with a solution of saccharum saturni, the writing, which disappears when dry, will appear legible, and of a brownish black, by barely holding it near the mouth of the bottle containing volatile tincture of sulphur. The vapours of this tincture are so exceedingly penetrating, that it is said they will even penetrate through a wall, so as to make a writing with saccharum saturni appear legible on the other side; but this is much to be doubted.

XIV. Of the PHENOMENA resulting from different mixtures of the Acid, Neutral, and Alkaline SALTS, already treated of.

1. If concentrated oil of vitriol is mixed with strong spirit of nitre, or spirit of salt, the weaker acid will become exceedingly volatile, and emit very elastic fumes; so that if a mixture of this kind is put into a close stopp'd bottle, it will almost certainly burst it. The same effect follows upon mixing spirit of salt and spirit of nitre together. In this case, both acids become surprisingly volatile; and much of the liquor will be dissipated in fumes, if the mixture is suffered to stand for any considerable time. Such mixtures ought therefore to be made only at the time they are to be used.

2. If vitriolated tartar is dissolved in an equal quantity of strong spirit of nitre, by heating them together in a matras, the stronger vitriolic acid will be displaced by the weaker nitrous one, and the liquor, on cooling, will shoot into crystals of nitre. The same thing happens also upon dissolving vitriolated tartar, or Glauber's salt, in spirit of salt. This observation we owe to Mons^r Beaumé. It seems to strike directly against the commonly received opinion of an *essential* superiority of strength in the vitriolic acid over the nitrous and marine acids; and would insinuate that one acid displaced another, not according to its *quality* but according to its *quantity*.

3. If vitriolated tartar, or Glauber's salt, is dissolved in water, and this solution mixed with another consisting of calcareous earth, silver, mercury, lead, or tin, dissolved in the nitrous or marine acids, the vitriolic acid will leave the fixed alkali with which it was combined, and, uniting with the calcareous earth or metal, fall with it to the bottom of the vessel. This decomposition takes place only when the vitriolic acid meets with such bodies as it cannot easily dissolve into a liquid, such as those we have just now mentioned: for though vitriolated tartar is mixed with a solution of iron, copper, &c. in the nitrous or marine acids, no decomposition takes place. The case is not altered, whatever acid is made use of; for the marine acid will effectually separate silver, mercury, or lead, from the vitriolic or nitrous acids. This, as well as the last observation, shews us, that the attractive power between acids and alkalis or metals, is exceedingly weakened by water.

4. According to Dr Lewis, if a solution of vitriolated tartar is dropt into lime-water, the acid will unite with the lime, and precipitate with it in an indissoluble

felenite, the alkali remaining in the water in a pure PRAC and caustic state.

5. If green vitriol is mixed with any solution containing substances which cannot be dissolved into a liquid by the vitriolic acid, the vitriol will be immediately decomposed, and the liquor will become a solution of iron only. Thus, if green vitriol is mixed with a solution of saccharum saturni, the vitriolic acid immediately quits the iron for the lead, and falls to the bottom with the latter, leaving the vegetable acid of the saccharum saturni to combine with the iron.

6. If solution of tin in aqua regia is mixed with solution of saccharum saturni, the marine acid quits the tin for the lead contained in the saccharum; at the same time, the acetous acid, which was combined with the lead, is unable to dissolve the tin which was before kept suspended by the marine acid. Hence, both the saccharum saturni, and solution of tin, are very effectually decomposed, and the mixture becomes entirely useless. Dyers and callico-printers ought to attend to this, who are very apt to mix these two solutions together; and no doubt many of the faults of colours dyed or printed in particular places, arise from injudicious mixtures of a similar kind. See DYEING.

7. If mild volatile alkali, that is, such as remains in a concrete form, by being united with a large quantity of fixed air, is poured into a solution of chalk in the nitrous or marine acids, the earth will be precipitated, and a true sal ammoniac formed. If the whole is evaporated to dryness, and a considerable heat applied, the acid will again part with the alkali, and combine with the chalk. Thus, in the purification of volatile alkalis by means of spirit of salt, the same quantity of acid may be made to serve a number of times. This will not hold in volatile spirits prepared with quicklime.

8. If equal parts of sal ammoniac and corrosive sublimate mercury are mixed together and sublimed, they unite in such a manner as never to be separable from one another without decomposition. The compound is called *sal alembroth*: which is said to be a very powerful solvent of metallic substances, gold itself not excepted. Its powers in this, or any other respect, are at present but little known. By repeated sublimations, it is said, this salt becomes entirely fluid, and refuses to arise in the strongest heat.

9. If vitriolic acid is poured upon any salt difficult of solution in water, it becomes then very easily soluble. By this means, vitriolated tartar, or cream of tartar, may be dissolved in a very small quantity of water.

SECT. II. Earths.

THE general divisions and characters of these substances we have given, n^o 33.; and most of their combinations with saline substances have been already mentioned. In this section, therefore, we have to take notice only of their various combinations with one another, with inflammable, or metallic substances, &c. As they do not, however, act upon one another till subjected to a vitrifying heat, the changes then induced upon them come more properly to be treated of under the article GLASS. Upon metallic, and inflammable substances, (sulphur alone excepted), they have very

33
Sal ale
broth.

PRACTICE

PRACTICE

very little effect; and therefore, what relates to these combinations shall be taken notice of in the following sections. We shall here confine ourselves to some remarkable alterations in the nature of particular earths by combination with certain substances, and to the phosphoric quality of others.

§ 1. Transmutation of FLINTS into an EARTH soluble in acids.

338
Solution of
flint.

This is effected by mixing powdered flints with alkaline salt, and melting the mixture by a strong fire. The melted mass deliquesces in the air, like alkaline salts; and if the flint is then precipitated, it becomes soluble in acids, which it entirely resisted before.

In this process the alkali, by its union with the flint, is deprived of its fixed air, and becomes caustic. To this causticity its solvent power is owing; and therefore the flint may be precipitated from the alkali, not only by acids, but by any substance capable of furnishing fixed air; such as magnesia alba, or volatile alkali. The precipitate in both cases proves the same; but the nature of it hath not hitherto been determined. Some have conjectured that the vitriolic acid existed in the flint; in which case, the alkali made use of in this process, ought to be partly converted into vitriolated tartar.

§ 2. Of PHOSPHORIC Earths.

339
Bolognian
stone.

These are so called from their property of shining in the dark. The most celebrated and anciently known of this kind is that called the *Bolognian stone*, from Bologna, a city in Italy, near which it is found. The discovery, according to Lémery, was accidentally made by a shoe-maker called Vincenzo Casciarolo; who used to make chemical experiments. This man, having been induced to think, from the great weight and lustre of these stones, that they contained silver, gathered some, and calcined them; when carrying them into a dark place, probably by accident, he observed them shining like hot coals.

Mr Margraaff describes the Bolognian stone to be an heavy, soft, friable, and crystallized substance, incapable of effervescence with acids before calcination in contact with burning fuel. These properties seem to indicate this stone to be of a selenitic or gypseous nature.

340
How rendered
luminous.

When these stones are to be rendered phosphoric, such of them ought to be chosen as are the cleanest, best crystallized, most friable and heavy; which exfoliate when broken, and which contain no heterogeneous parts. They are to be made red hot in a crucible; and reduced to a very fine powder in a glass-mortar, or upon a porphyry. Being thus reduced to powder, they are to be formed into a paste with mucilage of gum tragacanth, and divided into thin cakes. These are to be dried with a heat which at last is to be made pretty considerable. An ordinary reverberating furnace is to be filled to three quarters of its height with charcoal, and the fire is to be kindled. Upon this charcoal, the flat surfaces of the cakes are to rest, and more charcoal to be placed above them, so as to fill the furnace. The furnace is then to be covered with its dome, the tube of which is to remain

open; so the coal is to be consumed, and the furnace is to be left cool; the cakes are then to be cleansed from the ashes by blowing with bellows upon them. When they have been exposed during some minutes, to light, and afterwards carried to a dark place, they will seem to shine like hot coals; particularly if the person observing them has been sometime in the dark, or have shut his eyes, that the pupils may be sufficiently expanded. After this calcination through the coals, if the stones be exposed to a stronger calcination, during a full half hour, under a musket, their phosphoric quality will be rendered stronger.

From attending to the qualities of this stone, and the requisites for making this phosphorus, we are naturally led to think, that the Bolognian phosphorus is no other than a composition of sulphur and quicklime. The stone itself, in its natural state, evidently contains vitriolic acid, from its not effervescing with acids of any kind. This acid cannot be expelled from earthy substances by almost any degree of fire, unless inflammable matter is admitted to it. In this case, part of the acid becomes sulphureous, and flies off; while part is converted into sulphur, and combines with the earth. In the above mentioned process, the inflammable matter is furnished by the coals in contact with which the cakes are calcined, and by the mucilage of gum tragacanth with which the cakes are made up. A true sulphur must therefore be formed by the union of this inflammable matter with the vitriolic acid contained in the stone; and part of this sulphur must remain united to the earth left in a calcareous state, by the dissipation, or conversion into sulphur, of its acid.

In the year 1730, a memoir was published by Mr du Fay, wherein he asserts, that all calcareous stones, whether they contain vitriolic acid or not, are capable of becoming luminous by calcination; with this difference only, that the pure calcareous stones require a stronger, or more frequently repeated, calcination to convert them into phosphorus; whereas those which contain an acid, as selenites, gypsum, spar, &c. become phosphoric by a slighter calcination. On the contrary, Mr Margraaff asserts, that no other stones can be rendered phosphoric but those which are saturated with an acid; that purely calcareous stones, such as marble, chalk, limestone, flintalices, &c. cannot be rendered luminous, till saturated with an acid, previously to their calcination.

We have already taken notice, n° 192, 225, that the compounds formed by uniting calcareous earths with the nitrous and marine acids become a kind of phosphori; the former of which emits light in the dark, after having been exposed to the sun through the day; and the latter becomes luminous by being struck. Signior Beccaria found, that this phosphoric quality was capable of being given to almost all substances in nature, metals perhaps excepted. He found that this quality was widely diffused among animals, and that even his own hand and arm possessed it in a very considerable degree. In the year 1775, a treatise on this kind of phosphori was published by B. Wilson, P. R. S. and member of the Royal Academy at Upsal. In this treatise he shews, that oyster-shells, by calcination, acquire the phosphoric quality in a very great degree,

either

PRACTICE either when combined with the nitrous acid, or without it.

The first experiment made by our author was the pouring some aqua fortis, previously impregnated with copper, on a quantity of calcined oyster-shells, so as to form them into a kind of paste; he put this paste into a crucible, which was kept in a pretty hot fire for about 40 minutes. Having taken out the mass, and waited till it was cool, he presented it to the external light. On bringing it back suddenly into the dark, he was surprised with the appearance of a variety of colours like those of the rainbow, but much more vivid. In consequence of this appearance of the prismatic colours, he repeated the experiment in various ways, combining the calcined oyster-shells with different metals and metallic solutions, with the different acids, alkaline and neutral salts, as well as with sulphur, charcoal, and other inflammable substances; and by all of these he produced phosphori, which emitted variously coloured light.

345
Surprising
phosphoric
quality of
oyster-
shells.

What is more remarkable, he found that oyster-shells possessed the phosphoric quality in a surprising degree; and for this purpose nothing more was requisite than putting them into a good sea-coal fire, and keeping them there for some time. On scaling off the internal yellowish surface of each shell, they become excellent phosphori, and exhibit the most vivid and beautiful colours. As we know that neither the vitriolic nor any other acid is contained in oyster-shells, we cannot as yet say any thing satisfactory concerning the nature of this phosphorus.

§ 3. Of the VEGETABLE Earth.

346
Dr Lewis's
opinion.

This is produced from vegetables by burning; and, when perfectly pure, by lixiviating the ashes with water, to extract the salt; and then repeatedly calcining them, to burn out all the inflammable matter; and is perhaps the same, from whatever substance it was obtained: in this state, according to Dr Lewis, it is of the same nature with magnesia. In the state, however, in which this earth is procurable by simply burning the plant, and lixiviating the ashes, it is considerably different, according to the different plants from which it is obtained. The ashes of mugwort, small centaury, chervil, and dill, are of a brownish grey; goat's-beard and lungwort afford white ashes; those of fennel are whitish; those of Roman wormwood of a greenish grey; those of rue, agrimony, saxifrage, brown; those of tansy, of a dusky green; those of dodder, of a fine green; eyebright, southern-wood, common wormwood, and scabious, afford them grey; scurvy-grass, of a whitish grey; hyssop, yarrow, and sowbane, of a dusky grey; melilot, and oak-leaves, as also plantain, colts-foot, pine-tops, and fumitory, of a dusky brown; penny-royal, of a pale brown, with some spots of white; elder-flowers, sage, and mother of thyme, afford yellow ashes; those of strawberry-leaves are of a pale brimstone colour; those of cat-mint, of a dusky red; of prunella, brick-coloured; of honey-suckle, blue; of fern, blackish; and those of St John's-wort, feverfew, origanum, and pimpernel, are all of a deep black. The only use to which this kind of earth has yet been put, is that of glass-making and manure. (See GLASS, and AGRICULTURE.)

347
Mr Gmelin's ex-
periments.

SECT. III. Of Metallic Substances.

I. GOLD.

THIS metal is reckoned of all others the most perfect and indestructible. When in its greatest purity, it has very little elasticity, is not sonorous, its colour is yellow, it is exceedingly soft and flexible, and is more ductile than any other metal whatever. (See GOLD Leaf, and WIRE-DRAWING.) Of all bodies it is the most ponderous; its gravity being to that of water, according to Dr Lewis, as 19,280, or 19,290, to 1. For its fusion it requires a low degree of white heat, somewhat greater than that in which silver melts. Whilst fluid, it appears of a bluish green colour; when cold, its surface looks smooth, bright, and considerably concave: it seems to expand more in the act of fusion, and to shrink more in its return to solidity, than any of the other metals; whence the greater concavity of its surface. Before fusion it expands the least of all metals, except iron. By sudden cooling it becomes, as well as other metals, brittle; which effect has been erroneously attributed to the contact of fuel during fusion.

348
Specific
gravity.

Gold amalgamates very readily with mercury, and mingles in fusion with all the metals. It is remarkably disposed to unite with iron; of which it dissolves many times its own weight, in a heat not much greater than that in which gold itself melts; the mixture is of a silver colour, very brittle, and hard. All the metals, except copper, debase the colour of gold; and, if their quantity is nearly equal to that of the gold, almost entirely conceal it. All but copper and silver destroy its malleability; but none so remarkably as tin and lead; a most minute portion, even the vapour, of these metals, renders gold extremely brittle; though a small proportion of gold forms with them compounds sufficiently ductile; more so than either the lead or tin by themselves. When gold is struck during a certain time by a hammer, or when violently compressed, as by the wire-drawers, it becomes more hard, elastic, and less ductile; so that it is apt to be cracked and torn. Its ductility is, however, restored by the same means used with other metals, namely, heating it red hot, and letting it cool slowly. This is called annealing metals; and gold seems to be more affected by this operation than any other metal. The tenacity of the parts of gold is also very surprising; for a wire of $\frac{1}{2}$ of an inch in diameter will support a weight of 500 pounds.

349
Surprising
tenacity of
its parts.

Gold is unalterable by air, or water. It never contracts rust like other metals. The action of the fiercest furnace-fires occasions no alteration in it. Kunkel kept gold in a glass-house furnace for a month, and Boyle kept some exposed to a great heat for a still longer time, without the loss of a single grain. It is said, however, to be dissipated in the focus of a large burning mirror.

350
Not liable
to rust.

Mr Boyle relates a very curious and extraordinary experiment, which he thought was sufficient to prove the total destructibility of gold. About an eighth part of a grain of powder, communicated by a stranger, was projected upon two drachms of fine gold in fusion, and the matter kept melted for a quarter of an hour.

351
Mr Boyle's
experi-
ments for
the destruc-
tion of gold.

PRACTICE

hour. During the fusion, the matter looked like ordinary gold; except only once, that his assistant observed it to look exactly of the colour of opal. When cold, it was of a dirty colour, and, as it were, overcast with a thin coat, almost like half-vitrified litharge: the bottom of the crucible was overlaid with a vitrified substance, partly yellow, and partly reddish brown; with a few small globules, more like impure silver than gold. The metal was brittle, internally like brass, or bell-metal; on the touchstone more like silver than gold: its specific gravity was to that of water only as $15\frac{1}{2}$ to 1. There was no absolute loss of weight. By cupellation, 60 grains of this mass yielded 53 grains of pure gold; with seven grains of a ponderous, fixed, dark-coloured substance.

352.
Solution in
aqua regia.

We have already mentioned, that in certain circumstances gold is soluble in the nitrous and marine acids separately. It is, however, always soluble by the two united, but dissolves slowly even then. The most commodious method of obtaining this solution is, by putting the gold, either in leaves, or granulated, or cut into small thin pieces, into a proper quantity of aqua fortis; then adding, by degrees, some powdered sal ammoniac, till the whole of the gold is dissolved. By this means a much smaller quantity of the menstruum proves sufficient, than if the sal ammoniac was previously dissolved in the aqua fortis; the conflict, which each addition of the salt raises with the acid, greatly promoting the dissolution. Aqua fortis of moderate strength will, in this way, take up about one-third of its weight of gold; whereas an aqua regia, ready prepared from the same aqua fortis, will not take up above one-fifth its weight. Common salt answers better for the preparation of the aqua regia, than sal ammoniac.

353.
Properties
of the solution.

This solution, like all other metallic ones, is corrosive. It gives a violet colour to the fingers, or to any animal matters. If the solution is evaporated and cooled, yellow transparent crystals will be formed: but, if the evaporation is carried too far, the acids with which the gold is combined may be driven from it, by heat alone; and the gold will be left in the state of a yellow powder, called *calx of gold*.

354.
Gold precipitated
from it.

Gold may be precipitated from its solution by those substances which commonly precipitate metals, such as alkaline salts, and calcareous earths. It may also be precipitated in a fine purple powder, by tin, or its solution.

When fixed alkalies are made use of, the precipitate weighs about one-fourth more than the gold employed. With volatile alkalies also, if they are added in no greater proportion than is sufficient to saturate the acid, the quantity of precipitate proves nearly the same: but if volatile spirit is added in an over-proportion, it re-dissolves part of the gold which it had before precipitated, and the liquor becomes again considerably yellow. The whole of the precipitate, however, could not be re-dissolved, either by the mild or caustic alkali; nor did either of these spirits sensibly dissolve, or extract any tinge from precipitates of gold which had been thoroughly edulcorated with boiling water.

All the metallic bodies which dissolve in aqua regia, precipitate gold from it. Mercury and copper throw

Vol. III.

down the gold in its bright metalline form; as the others, in that of a calx or powder, which has no metallic aspect. Vitriol of iron, though it precipitates gold, yet has no effect upon any other metal; hence it affords an easy method of separating gold from all other metals. The precipitation with tin succeeds certainly, only when the metal in substance is used, and the solution of gold largely diluted with water. It is observable, that though the gold is precipitated from the diluted solution by tin, yet, if the whole is suffered to stand till the water has in a great measure exhaled, the gold is taken up afresh, and only a white calx of tin remains.

If gold is precipitated from its solution in aqua regia, by a volatile alkali, the precipitate will explode with a prodigious force and noise if too strongly heated. This preparation is called *aurum fulminans*. The reason of this explosion probably is, the sudden expansion of the fixed air contained in the calx, occasioned by the deflagration of a small quantity of nitrous ammoniacal salt produced during the precipitation.

The explosion of aurum fulminans is one of the most violent known in chemistry. The report is preceded by a flash, visible in the dark; and, during the explosion, the gold is revived into little granules, which may be caught by a proper apparatus. It is not necessary that fulminating gold should be touched by an ignited body, or made red hot, in order to make it explode. The heat requisite for this purpose, is intermediate between that of boiling water and the heat which makes metals of an obscure red colour. If a little of it is laid upon a smooth piece of metal, and then heated so as to explode, the vehement quickness and strength of the explosion will make a small hollow in the metal. From this it has been thought that fulminating gold directed its force only, or chiefly, downwards. This, however, seems not to be the case; but rather, that it acts equally in all directions. Friction, likewise, and even a friction that is not very considerable, is sufficient to make this substance explode; and these circumstances render fulminating gold very dangerous. The author of the Chemical Dictionary relates the following accident, to which he says he was witness: "A young man who worked in a laboratory, had put a drachm of fulminating gold into a bottle, and had neglected to wipe the inner surface of the neck of the bottle, to which some of the powder adhered. When he endeavoured to close the bottle, the turning of the glass stopper round, in order to make it fit more closely, occasioned such a friction, that heat enough was produced to make part of the powder explode. By this explosion the young man was thrown some steps behind, his face and hands were wounded by the fragments of the bottle, and his eyes were put out. Notwithstanding this violent explosion, the whole drachm of fulminating gold certainly was not exploded; for much of it was afterwards found scattered about the laboratory." Of this mischievous quality the gold may easily be deprived, by boiling it in oil of vitriol, or mixing it with sulphur, and burning away the sulphur.

If gold is melted with an hepar sulphuris, composed of equal parts of sulphur and fixed alkaline salt, the

metal readily unites with it into an uniform mass, capable of dissolution in water without any separation of its parts. The solution, besides a nauseous taste from the sulphur, has a peculiar penetrating bitterness, not discoverable in any other metalline solution made by the same means.

Though the compositions of sulphur and alkali seem to unite more intimately with gold than any other metal, their affinity with it is but slight; copper, or iron, added to the matter in fusion, disunite, and precipitate the gold. The metal thus recovered, and purified by the common processes, proves remarkably paler-coloured than at first. In an experiment related by Dr Brandt, in the Swedish Memoirs, the purified gold turned out nearly as pale as silver, without any diminution of weight.

360
Medical
virtues of
gold.

Gold has been thought to be possessed of many extraordinary virtues as a medicine; which, however, are long ago determined to be only imaginary. It is not indeed very easy to prepare this metal in such a manner that it can be safely taken into the human body. The solution in aqua regia is poisonous; but if any essential oil is poured on this solution, the gold will be separated from the acid, and united to the essential oil, with which, however, it contracts no lasting union, but in a few hours separates in bright yellow phlegm to the sides of the glass. Vitriolic ether dissolves the gold more readily and perfectly than the common essential oils; and keeps it permanently suspended, the acid liquor underneath appearing colourless. The yellow ethereal solution poured off, and kept for some time in a glass stoped with a cork, so that the spirit may slowly exhale, yields long, transparent, prismatic crystals, in shape like those of nitre, and yellow like topaz. What the nature of these crystals is, either as to medicinal effects, or other purposes, is as yet unknown.

361
Ethereal so-
lution.

Rectified spirit of wine mingles uniformly with the solution of gold made in acids; if the mixture is suffered to stand, for some days, in a glass slightly covered, the gold is by degrees revived, and arises in bright pellicles to the surface. Grosser inflammable matters, wine, vinegar, solutions of tartar, throw down the gold, in its metalline form, to the bottom. Gold is the only metal which is thus separable from its solution in acids by these substances; and hence gold may be purified by these means from all admixtures, and small proportions of it in liquors readily discovered.

362
Colour of
gold re-
solved.

When the colour of gold is by any means rendered pale, it may be recovered again by melting it with copper, and afterwards separating the copper; or by a mixture of verdigrease and sal ammoniac with vitriol or nitre. The colour is also improved by fusion with nitre, injecting sal ammoniac upon it in the fusion, quenching it in urine, or boiling it in a solution of alum. When borax is used as a flux, it is customary to add a little nitre or sal ammoniac, to prevent its being made pale by the borax. Juncker reports, that by melting gold with four times its weight of copper, separating the copper by aqua fortis unpurified, then melting the gold with the same quantity of fresh copper, and repeating this process eight or nine times, the gold becomes at length of a deep red colour, which sustains the action of lead, antimony, and aqua fortis.

PRACTICE

2. SILVER.

This, next to gold, is the most perfect, fixed, and ductile of all the metals. Its specific gravity is to that of water nearly as 11 to 1. A single grain has been drawn into a wire three yards long, and flattened into a plate an inch broad. In common fires it suffers no diminution of its weight; and, kept in the vehement heat of a glass-house for a month, it loses no more than one sixty-fourth. In the focus of a large burning-glass, it smokes for a long while, then contracts a greyish ash on the surface, and at length is totally dissipated.

363 -
Ductility
of silver.

Silver is somewhat harder and more sonorous than gold, and is fusible with a less degree of heat. The tenacity of its parts also is nearly one half less than that of gold; a silver wire of $\frac{1}{8}$ of an inch diameter being unable to bear more than 270 pounds.

Mercury unites very readily with silver-leaf, or with the calx of silver precipitated by copper; but does not touch the calces precipitated by alkaline salts. The vapours of sulphureous solutions stain silver yellow or black. Sulphur, melted with silver, debases its colour to a leaden hue, renders it more easily fusible than before, and makes it flow thin as to be apt in a little time to penetrate the crucible: in a heat just below fusion, a part of the silver shoots up, all over the surface, into capillary efflorescences. Aqua fortis does not act upon silver in this compound; but fixed alkaline salts will absorb the sulphur, and form a hepar sulphuris, which, however, is capable of again dissolving the metal. If the sulphurated silver is mixed with mercury sublimata, and exposed to the fire, the mercury of the sublimate will unite with the sulphur, and carry it up in the form of cinnabar, whilst the marine acid of the sublimate unites with the silver, into a luna cornea, (see n° 239), which remains at the bottom of the glass. Fire alone is sufficient, if continued for some time, to expel the sulphur from silver.

364 -
Effects of
sulphur on.

From the baser metals, silver is purified by cupellation with lead. (See REFINING.) It always retains, however, after that operation, some small portion of copper, sufficient to give a blue colour to volatile spirits, which has been erroneously thought to proceed from the silver itself. It is purified from this admixture by melting it twice or thrice with nitre and borax. The scoria, on the first fusion, are commonly blue; on the second, green; and on the third, white, which is a mark of the purification being completed.

365
Purificati-
on.

The most effectual means, however, of purifying silver, is by reviving it from luna cornea; because spirit of salt will not precipitate copper as it does silver. The silver may be recovered from luna cornea, by fusion with alkaline and inflammable fluxes; but, in these operations, some loss is always occasioned by the dissipation of part of the volatile calx, before the alkali or metal can absorb its acid.

366
Luna cor-
nea redu-
ced.

Mr Margraaf has discovered a method of recovering the silver with little or no loss; mercury assailed by volatile salts, inhibiting it by trituration without heat. One part of luna cornea, and two of volatile salt, are to be ground together in a glass-mortar, with so much water as will reduce them to the consistence of a thin paste, for a quarter of an hour or more; five parts of pure

367
Mr Mar-
graaf's me-
thod.

PRACTICE

pure quicksilver are then to be added, with a little more water, and the triture to be continued for some hours. A fine amalgam will thus be obtained; which is to be washed with fresh parcels of water, as long as any white powder separates. Nearly the whole of the silver is contained in the amalgam, and may be obtained perfectly pure by distilling off the mercury. The white powder holds a small proportion separable by gentle fublimation; the matter which sublimes is nearly similar to *mercurius dulcis*.

The colour of silver is debased by all the metals, and its malleability greatly injured by all but gold and copper. The English standard-silver contains one part of copper to twelve and one-third of pure silver. This metal discovers in some circumstances a great attraction for lead; though it does not retain any of that metal in cupellation. If a mixture of silver and copper be melted with lead in certain proportions, and the compound afterwards exposed to a moderate fire, the lead and silver will melt out together, bringing very little of the copper with them; by this means silver is often separated from copper in large works. The effect does not wholly depend upon the different fusibility of the metals; for if tin, which is still more fusible than lead, be treated in the same manner with a mixture of silver and copper, the three ingredients are found to attract one another so strongly as to come all into fusion together. Again, if silver be melted with iron, and lead added to the mixture, the silver will forsake the iron to unite with the lead, and the iron will float by itself on the surface.

Silver is purified and whitened externally by boiling in a solution of tartar and common salt. This is no other than an extraction of the cupreous particles from the surface of the silver, by the acid of the tartar acted by the common salt.

3. COPPER.

This is one of those metals, which, from their destructibility by fire, and contracting rust in the air, are called *impure*. Of these, however, it is the most perfect and indestructible. It is of a reddish colour when pure; easily tarnishes in a moist air, and contracts a green rust. It is the most sonorous of all the metals, and the hardest and most elastic of all but iron. In some of its states, copper is as difficultly extended under the hammer as iron, but always proves softer to the file; and is never found hard enough to strike a spark with flint or other stones; whence its use for chisels, hammers, hoops, &c. in the gunpowder works. When broke by often bending backwards and forwards, it appears internally of a dull red colour without any brightness, and of a fine granulated texture, resembling some kinds of earthen ware. It is considerably ductile, though less so than either gold or silver; and may be drawn into wire as fine as hair, or beaten into leaves almost as thin as those of silver. The tenacity of its parts is very considerable; for a copper wire of $\frac{1}{4}$ of an inch diameter will support a weight of 209 pounds without breaking. The specific gravity of this metal, according to Dr Lewis, is to that of water as 8.830 to 1.

Copper continues malleable when heated red; in which respect it agrees with iron; but is not, like iron,

capable of being welded, or having two pieces joined into one. It requires for its fusion a stronger heat than either gold or silver, though less than that requisite to melt iron. When in fusion, it is remarkably impatient of moisture; the contact of a little water occasioning the melted copper to be thrown about with violence, to the great danger of the by-standers. It is, nevertheless, said to be granulated in the brass-works at Bristol, without explosion or danger, by letting it fall in little drops, into a large cistern of cold water covered with a brass-plate. In the middle of the plate is an aperture, in which is secured with Sturbridge clay a small vessel, whose capacity is not above a spoonful, perforated with a number of minute holes, through which the melted copper passes. A stream of cold water passes through the cistern. It suffered to grow hot, the copper falls liquid to the bottom, and runs into plates.

Copper, in fusion, appears of a bluish green colour, nearly like that of melted gold. Kept in fusion for a long time, it becomes gradually more and more brittle; but does not scorch considerably, nor lose much of its weight. It is much less destructible than any of the imperfect metals, being very difficultly subdued even by lead or bismuth. If kept in a heat below fusion, it contracts on the surface thin powdery scales; which, being rubbed off, are succeeded by others, till the whole quantity of the metal is thus changed into a scoria or calx, of a dark reddish colour. This calx does not melt in the strongest furnace fires; but, in the focus of a large burning mirror, runs easily into a deep red, and almost opaque, glass. A flaming fire, and strong draught of air over the surface of the metal, greatly promote its calcination. The flame being tinged of a green, bluish, or rainbow colour, is a mark that the copper burns.

This metal is very readily soluble by almost all alkaline substances; even common water, suffered to stand long in copper-vessels, extracts so much as to gain a coppery taste. It is observable, that water is much more impregnated with this taste, on being suffered to stand in the cold, than if boiled for a longer time in the vessel. The same thing happens in regard to the mild vegetable acids. The confectioners prepare the most acid syrups, even those of lemons and oranges, by boiling in clean copper-vessels, without the preparations receiving any ill taste from the metal; whereas, either the juices themselves, or the syrups made from them, if kept cold in copper-vessels, soon become impregnated with a disagreeable taste, and with the pernicious qualities of the copper.

By combination with vegetable acids, copper becomes in some respects remarkably altered. Verdigris, which is a combination of copper with a kind of acetic or tartarous acid, is partially soluble in distilled vinegar; the residuum, on being melted with borax and linseed oil, yields a brittle metallic substance, of a whitish colour, not unlike bell-metal. The copper also, when revived from the distilled verdigris, was found by Dr Lewis to be different from the metal before dissolution; but neither of these changes have yet been sufficiently examined.

Copper, in its metallic state, is very difficultly amalgamated with mercury; but unites with it more easily

PRACTICE fily if divided by certain admixtures. If mercury and verdigrease be triturated together with common salt, vinegar, and water, the copper in the verdigrease will be imbibed by the mercury, and form with it, as Boyle observes, a curious amalgam, at first so soft as to receive any impression, and which, on standing, becomes hard like brittle metals. Brads-leaf likewise gives out its copper to mercury, the other ingredient of the brads separating in the form of powder.

376
Dr Lewis's
method.

Easier methods of amalgamating copper are published by Dr Lewis in his notes on Willon's chemistry, p. 432. His receipts are,—“ Dissolve some fine copper in aqua fortis: when the menstruum will take up no more of the metal, pour it into an iron mortar, and add six times the weight of the copper, of mercury, and a little common salt: grind the whole well together with an iron pestle; and, in a little time, the copper will be imbibed by the mercury, and an amalgam formed, which may be rendered bright by washing it well with repeated additions of water.

Another method. Take the muddy sublance which is procured in the polishing of copper plates with a pumice stone, and grind it well with a suitable portion of mercury, a little common salt, and some vinegar, in an iron mortar, (a marble one will do, if you make use of an iron pestle,) till you perceive the mercury has taken up the copper.” The copper recovered from these amalgams retains its original colour, without any tendency to yellow. Even when brads is made use of for making the amalgam, the recovered metal is perfect red copper; the ingredient from which the brads received its yellowness being, as above observed, separated in the amalgamation.

377
Brads, how
prepared.

Copper is the basis of several metals for mechanic uses; as brads, prince's metal, bell-metal, bath-metal, white copper, &c. Brads is prepared from copper and calamine, with the addition of powdered charcoal, cemented together, and at last brought into fusion. The calamine is to be previously prepared by cleansing it from adhering earth, stone, or other matters; by roasting, or calcining it; and by grinding it into a fine powder. The length of time, and degree of heat, requisite for the calcination of the calamine, are different according to the qualities of that mineral. The calamine, thus calcined, cleansed, and ground, is to be mixed with about a third or fourth part of charcoal dust, or powdered pit-coal, as is done in some parts of England. The malleability of the brads is diminished by the use of pit-coal, which is therefore only employed for the preparation of the coarser kinds. To this composition of calamine and coal, some manufacturers add common salt, by which the process of making brads is said to be hastened. In Gossard, where the calamine adhering to the insides of the furnaces is used instead of the native calamine, a small quantity of alum is added, by which they pretend the colour of the brads is heightened. With this composition, and with thin plates or grains of copper, the crucibles are to be nearly filled. The proportion of the calamine to the copper varies according to the richness of the former, but is generally as three to two. The copper must be dispersed through the composition of calamine and coal; and the whole must be covered with more coal, till the crucibles are full. The crucibles,

PRACTICE thus filled, are to be placed in a furnace sunk in the ground, the form of which is that of the frustum of a hollow cone. At the bottom of the furnace, or greater basis of the frustum, is a circular grate, or iron-plate. This plate is covered with a coat of clay and horse-dung, to defend it from the action of the fire; and pierced with holes, through which the air maintaining the fire passes. The crucibles stand upon the circular plate, forming a circular row, with one in the middle. The fuel is placed betwixt the crucibles, and is thrown into the furnace at the upper part of it, or the lesser basis of the frustum. To this upper part or mouth of the furnace is fitted a cover made of bricks or clay, kept together with bars of iron, and pierced with holes. This cover serves as a register. When the heat is to be increased, the cover must be partly or entirely taken off, and a free draught is permitted to the external air, which passes along a vault under-ground to the ash-hole, through the holes in the circular grate or plate, betwixt the crucibles, and through the upper mouth, along with the smoke and flame, into an area where the workmen stand, which is covered with a large dome or chimney, through which the smoke and air ascend. When the heat is to be diminished, the mouth of the furnace is closed with the lid; through the holes of which the air, smoke, and flame pass. The crucibles are to be kept red-hot during eight or ten hours; and in some places much longer, even several days, according to the nature of the calamine. During this time, the zinc rises in vapour from the calamine, unites with the copper, and renders that metal considerably more fusible than it is by itself. To render the metal very fluid, that it may flow into one uniform mass at the bottom, the fire is to be increased a little before the crucibles are taken out, for pouring off the fluid metal into molds. From 60 pounds of good calamine, and 40 of copper, 60 pounds of brads may be obtained, notwithstanding a considerable quantity of the zinc is dissipated in the operation. The quantity of brads obtained has been considerably augmented since the introduction of the method now commonly practised, of granulating the copper; by which means a larger surface of this metal is exposed to the vapour of zinc, and consequently less of that vapour escapes. To make the finer and more malleable kinds of brads, besides the choice of pure calamine and pure copper, some manufacturers cement the brads a second time with calamine and charcoal; and sometimes add to it old brads, by which the new is said to be meliorated.

Brads is brittle when hot; but so ductile when cold, that it may be drawn into very fine wire, and beat into very thin leaves. Its beautiful colour, malleability, and its fusibility, by which it may be easily cast into moulds, together with its being less liable to rust than copper, render it fit for the fabrication of many utensils.

Although zinc be fixed to a certain degree in brads, by the adhesion which it contracts with the copper; yet when brads is melted, and exposed to a violent fire, during a certain time, the zinc dissipates in vapours, and even flames away, if the heat be strong enough; and if the fire is long enough continued, all the zinc will be evaporated and destroyed, so that what remains is copper.

PRACTICE

378
Princes me-
tal.

Prince's metal is made by melting zinc in substance with copper; and all the yellow compound metals prepared in imitation of gold, are no other than mixtures of copper with different proportions of that ferri-metal, taken either in its pure state, or in its natural ore calamine, with an addition sometimes of iron-slings, &c. Zinc itself unites most easily with the copper; but calamine makes the most ductile compound, and gives the yellowest colour. Dr Lewis observes, that a little of the calamine renders the copper pale; that when it has imbibed about $\frac{1}{5}$ its own weight, the colour inclines to yellow; that the yellowness increases more and more, till the proportion comes to almost one half; that on further augmenting the calamine, the compound becomes paler and paler, and at last white. The crucibles, in which the fusion is performed in large works, are commonly tinged by the matter of a deep blue colour.

379
Bell-metal.

Bell-metal is a mixture of copper and tin; though both these metals finely are malleable, the compound proves extremely brittle. Copper is dissolved by melted tin easily and intimately, far more so than by lead. A small portion of tin renders this metal dull-coloured, hard, and brittle. Bell-metal is composed of about ten parts of copper to one of tin, with the addition commonly of a little brass or zinc. A small proportion of copper, on the other hand, improves the colour and consistency of tin, without much injuring its ductility. Pewter is sometimes made from one part of copper, and twenty or more of tin.

380
Dr Lewis's
observations on the
specific gra-
vity of the
metal.

It has long been observed, that though tin is specifically much lighter than copper, yet the gravity of the compound, bell-metal, is greater than that of the copper itself. The same augmentation of gravity also takes place where the lighter metal is in the greatest proportion; a mixture even of one part of tin with two of copper, turning out specifically heavier than pure copper. Most metallic mixtures answer to the mean gravity of the ingredients, or such as would result from a bare addition of parts. Of those tried by Dr Lewis, some exceeded the mean, but the greater number fell short of it; tin and copper were the only ones that formed a compound heavier than the heaviest of the metals separately.

381
White cop-
per.

White copper is prepared by mixing together equal parts of arsenic and nitre, injecting the mixture into a red-hot crucible, which is to be kept in a moderate fire, till they subside, and flow like wax. One part of this mixture is injected upon four parts of melted copper, and the metal, as soon as they appear thoroughly united together, immediately poured out. The copper, thus whitened, is commonly melted with a considerable proportion of silver, by which its colour is both improved and rendered more permanent. The white copper of China and Japan appears to be no other than a mixture of copper and arsenic. Geoffroy relates, that, on repeated fusions, it exhaled arsenical fumes, and became red copper, losing with its whiteness, one seventh of its weight.

4. IRON.

Iron is a metal of a greyish colour; soon tarnishing in the air into a dusky blackish hue; and in a short time contracting a yellowish, or reddish rust. It is the hard-

est of all metals; the most elastic; and, excepting platinum, the most difficult to be fused. Next to gold, iron has the greatest tenacity of parts; an iron wire, the diameter of which is the tenth part of an inch, being its capable of sustaining 450 pounds. Next to tin, it is the lightest of all the metals, losing between a seventh and eighth part of its weight when immersed in water. When very pure, it may be drawn into wire as fine as horse-hair; but is much less capable of being beaten into thin leaves than the other metals, excepting only lead.

Iron grows red-hot much sooner than any other metal; and this, not only from the application of actual fire, but likewise from strong hammering, friction, or other mechanic violence. It nevertheless melts the most difficultly of all metals except platinum; requiring, in its most fusible state, an intense, bright, white heat. When perfectly malleable, it is not fusible at all by the heat of furnaces, without the additions or the immediate contact of burning fuel; and, when melted, loses its malleability: all the common operations which communicate one of these qualities deprive it at the same time of the other; as if fusibility and malleability were in this metal incompatible. When exposed to the focus of a large burning mirror, however, it quickly fused, boiled, and emitted an ardent fume, the lower part of which was a true flame. At length it was changed into a blackish, vitrified scoria.

From the great waste occasioned by exposing iron to a red but especially to a white heat, this metal appears to be a combustible substance. This combustion is maintained, like that of all other combustible substances, by contact of air. Dr Hook, having heated a bar of iron to that degree called white heat, he placed it upon an anvil, and blowed air upon it by means of bellows, by which it burnt brighter and hotter. Exposed to a white heat, it contracts a semi-vitreous coat, which bursts at times, and flies off in sparkles. No other metallic body exhibits any such appearance. On continuing the fire, it changes by degrees into a dark red calx, which does not melt in the most vehement heat procurable by furnaces, and, if brought into fusion by additions, yields an opaque black glass. When strongly heated, it appears covered on the surface with a soft vitreous matter like varnish. In this state pieces of it cohere; and, on being hammered together, weld, or unite, without discovering a juncture. As iron is the only metal which exhibits this appearance in the fire, so it is the only one capable of being welded. Those operations which prevent the superficial scorification, deprive it likewise of this valuable property: which may be restored again, by suffering the iron to resume its vitreous aspect; and, in some measure, by the interposition of foreign vitreifiable matters; whilst none of the other metals will unite in the smallest degree, even with its own scoria.

Iron expands the least of all metals by heat. In the act of fusion, instead of continuing to expand, like the other metals, it shrinks; and thus becomes so much more dense as to throw up such part as is unmelted, to the surface; whilst pieces of gold, silver, copper, lead, or tin, put into the respective metals in fusion, sink freely to the bottom. In its return to a consistent state, instead of shrinking like the other metals, it expands;

PRACTICE expands; sensibly rising in the vessel, and assuming a convex surface, while the others become concave. This property, first observed by Reaumur, excellently fits it for receiving impressions from moulds. By the increase of bulk which the metal receives in congelation, it is forced into the minutest cavities, so as to take the impression far more exactly than the other metals which shrink.

386
Dissolved
by all me-
tals except
lead and
mercury.

Iron is dissolved, by all the metals made fluid, except lead; though none of them act so powerfully upon it as gold: but, as Cramer observes, if the iron contains any portion of Sulphur, it can scarcely be made to unite at all with gold.

Among the semi-metallic bodies, it is averse to an union with mercury; no method of amalgamating these two having yet been discovered; though quicksilver, in certain circumstances, seems in some small degree to act upon it. A plate of tough iron, kept immersed in mercury for some days, becomes brittle; and mercury will often adhere to and coat the ends of iron pestles used in triturating certain amalgams with saline liquors.

Next to mercury, zinc is the most difficultly combined with iron; not from any natural indisposition to unite, but from the zinc being difficultly made to sustain the heat requisite. The mixture is hard, somewhat malleable, of a white colour approaching to that of silver. Regulus of antimony, as soon as it melts, begins to act on iron, and dissolves a considerable quantity. If the regulus be stirred with an iron rod, it will melt off a part of it. Arsenic likewise easily mingles with iron, and has a strong attraction for it; forsaking all the other metals, to unite with this. It renders the iron white, very hard, and brittle.

387
Prussian
blue.

This metal is the basis of the fine blue pigment, called, from the place where it was first discovered, *Berlin* or *Prussian* blue. This colour was accidentally discovered about the beginning of the present century, by a chemist of Berlin, who, having successively thrown upon the ground several liquors from his laboratory, was much surprised to see it suddenly stained with a beautiful blue colour. Recollecting what liquors he had thrown out, and observing the same effects from a similar mixture, he prepared the blue for the use of painters; who found that it might be substituted to ultramarine, and accordingly have used it ever since.

388
Dr Woodward's
receipt for.

Several chemists immediately endeavoured to discover the composition of this pigment; and, in the year 1724, Dr Woodward published the following process, in the *Philosophical Transactions*, for making it. "Alkalis together four ounces of nitre, and as much tartar; (See n° 220). Mix this alkali well with four ounces of dried bullocks blood; and put the whole in a crucible covered with a lid, in which there is a small hole. Calcine with a moderate heat, till the blood be reduced to a perfect coal; that is, till it emits no more smoke or flame capable of blackening any white bodies that are exposed to it. Increase the fire towards the end, so that the whole matter contained in the crucible shall be moderately, but sensibly, red.

"Throw into two pints of water the matter contained in the crucible, while yet red, and give it half an hour's boiling: decant this first water; and pour more upon the black charry coal, till it becomes almost

insipid. Mix together all these waters; and reduce them, by boiling, to about two pints.

"Dissolve also two ounces of martial vitriol, and eight ounces of alum, in two pints of boiling water. Mix this solution when hot with the preceding lixivium also hot. A great effervescence will then be made: the liquors will be rendered turbid; and will become of a green colour, more or less blue; and a precipitate will be formed of the same colour. Filtrate, in order to separate this precipitate; upon which pour spirit of salt, and mix them well together; by which means the precipitate will become of a fine blue colour. It is necessary to add rather too much of the salt than too little, and till it no longer increases the beauty of the precipitate. The next day wash this blue, till the water comes off from it insipid; and then gently dry it."

Mr Geoffroy was the first who gave any plausible theory of this process, or any rational means of improving it. He observes, that the Prussian blue is no other than the iron of the vitriol revived by the inflammable matter of the alkaline lixivium, and perhaps a little brightened by the earth of alum; that the green colour proceeds from a part of the yellow ferruginous calx, or ochre, unrevived, mixing with the blue; and that the spirit of salt dissolves this ochre more readily than the blue part; though it will dissolve that also by long standing, or if used in too large quantity. From these principles, he was led to increase the quantity of inflammable matter; that there might be enough to revive the whole of the ferruginous ochre, and produce a blue colour at once, without the use of the acid spirit. In this he perfectly succeeded; and found, at the same time, that the colour might be rendered of any degree of deepness, or lightness, at pleasure. If the alkali is calcined with twice its weight of dried blood, and the lixivium obtained from it poured into a solution of one part of vitriol to six of alum, the liquor acquires a very pale blue colour, and deposits as pale a precipitate. On adding more and more of a fresh solution of vitriol, the colour becomes deeper and deeper, almost to blackness. He imagines with great probability, that the blue pigment, thus prepared, will prove more durable in the air, mingle more perfectly with other colours, and be less apt to injure the lustre of such as are mixed with or applied in its neighbourhood, than that made in the common manner; the tarnish to which common Prussian blue is subject, seeming to proceed from the acid, which cannot be separated by any abluion.

He takes notice of an amusing phenomenon, which happens upon mixture. When the liquors are well stirred together; and the circular motion, as soon as possible, stopped; some drops of solution of vitriol, (depurated by long settling), let fall on different parts of the surface, divide, spread, and form curious representations of flowers, trees, shrubs, flying insects, &c. in great regularity and perfection. These continue 10 or 12 minutes: and on stirring the liquor again, and dropping in some more of the solution of vitriol, are succeeded by a new picture.

This theory is confirmed by Mr Macquer, in a *Mc-Mac-moir* printed in the year 1752. He observes, that the quantity of phlogiston communicated to the iron

PRACTICE in this process is so great, as not only to cause the metal resist in a great measure the action of acids, and become totally unaffected by the magnet; but by a slight calcination it becomes entirely similar to other iron, and is at once deprived of its blue colour. He further observes, that fire is not the only means by which Prussian blue may be deprived of all the properties which distinguish it from ordinary iron. A very pure alkali produces the same effect. He has also discovered, that the alkali which has thus deprived the Prussian blue of all the properties which distinguish it from ordinary iron, becomes, by that operation, entirely similar to the phlogisticated alkali used for the preparation of Prussian blue.

292
Phlogisticated alkali loses its alkaline properties.

By a more particular examination, he found, that the alkali might become perfectly saturated with the colouring matter; so that, when boiled on Prussian blue, the alkali extracted none of its colour. When the salt was thus perfectly saturated, it seemed no longer to possess any alkaline qualities. If poured into a solution of iron in any acid, a single, homogeneous, and perfect precipitate was formed; not green, as in Dr Woodward's process, but a perfect Prussian blue; which needed no acid to brighten its colour. A pure acid added to the alkali was not in the least neutralized, nor in the least precipitated the colouring matter. From hence Mr Macquer concludes, that, in the making of Prussian blue, vitriol is decomposed; because the iron has a strong attraction for the colouring matter, as well as the acid for the alkali; and the sum of the attraction of the acid to the alkali, joined to that of the iron for the colouring matter, is greater than the single attraction of the acid to the metal.

293
Earths do not attract the colouring matter.

Another very important phenomenon is, that earths have not the same attraction for this colouring matter that metallic substances have. Hence, if an alkali saturated with this colouring matter be poured into a solution of alum, no decomposition is effected, nor any precipitate formed. The alum continues alum, and the alkali remains unchanged. From this experiment Mr Macquer concludes that alum does not directly contribute to the formation of the Prussian blue. The purpose he thinks it answers is as follows. Fixed alkaline salts can never be perfectly saturated with phlogistic matter by calcination; alkalies, therefore, though calcined with inflammable substances, so as to make a proper lixivium for Prussian blue, remains still alkaline. Hence, when mixed with a solution of green vitriol, they form, by their purely alkaline part, a yellow precipitate, so much more copious, as the alkali is less saturated with phlogiston. But nothing is more capable of spoiling the fine colour of the Prussian blue, than an admixture of this yellow precipitate: it is therefore necessary to add a quantity of alum, which will take up the greatest part of the purely alkaline salt; and, of consequence, the quantity of yellow ferruginous precipitate is much diminished. But the earth of alum, being of a fine shining white, does not in the least alter the purity of the blue colour, but is rather necessary to dilute it. From all this it follows, that it is a matter of indifference whether the green precipitate is to be again dissolved by an acid, or the alkaline part of the lixivium saturated with alum, or with an acid, before the precipitate is formed. The latter indeed

seems to be the most eligible method.

Most alkalies obtained from the ashes of vegetables, being combined, by their combustion, with a portion of inflammable matter, are capable of furnishing a quantity of Prussian blue, proportionable to the quantity of colouring matter they contain, even without the necessity of mixing them with a solution of iron; because they always contain a little of this metal dissolved, some of which may be found in almost all vegetables; therefore, it is sufficient to saturate them with an acid. Henckel observed the production of this blue in the saturation of the fossil alkali, and recommended to chemists to inquire into its nature.

Iron desigrates with nitre, and renders the salt alkaline and caustic. A part of the iron is thus rendered soluble, along with the alkaliized salt. A mixture of equal parts of iron filings and nitre, injected into a strongly heated crucible, and, after the detonation, thrown into water, tinges the liquor of a violet or purplish blue colour. This solution, however, is not permanent. Though the liquor at first passes through a filter, without any separation of the iron; yet, on standing for a few hours, the metal falls to the bottom, in form of a brick-coloured powder. Volatile alkalies instantly precipitate the iron from this fixed alkaline solution.

Iron readily unites with sulphur; and when combined with it, proves much easier of fusion than by itself. A mixture of iron filings and sulphur, moistened with water, and pressed down close, in a few hours swells and grows hot; and, if the quantity is large, bursts into flame.

By cementation with inflammable matters, iron imbibes a larger quantity of phlogiston; and becomes much harder, less malleable, and more fusible. It is then called *steel*. See METALLURGY, and STEEL.

5. LEAD.

Lead is a pale or livid-white metal, soon losing its brightness in the air, and contracting a blackish or greyish ash-colour. It is the softest and most flexible of all metallic bodies; but not ductile to any great degree, either in the form of wire, or leaf; coming far short, in this respect, of all other metals. It has also the least tenacity of all metallic bodies; a leaden wire of $\frac{1}{8}$ of an inch diameter being capable of supporting only 29½ pounds. Lead has, however, a considerable specific gravity; losing, when immersed in water, between $\frac{1}{7}$ and $\frac{1}{8}$ of its weight. It is of all metals the most fusible, excepting only tin and bismuth. The plumbers cast thin sheets of lead upon a table or mould, covered with a woollen, and above this with a linen-cloth, without burning or scorching the cloths. The melted lead is received in a wooden case without a bottom; which being drawn down the sloping table by a man on each side, leaves a sheet of its own width, and more or less thin according to the greater or less celerity of its descent. For thick plates, the table is covered over with moistened sand, and the liquid metal conducted evenly over it, by a wooden strike, which bears on a ledge at each side.

Some have preferred, for mechanic uses, the melted lead, or flatted sheets, to the cast; as being more equal, smooth, and solid. But whatever advantage of this kind

PRACTICE

PRACTICE

kind the milled sort may appear to have at first, they are not found to be very durable. When the lead is stretched between the rollers, its cavities must necessarily be enlarged. The particles of metal that may be squeezed into them can have no union or adhesion with the contiguous particles; and, of consequence, must be liable, from bending, blows, jars, &c. to start out again, and leave the mass spongy and porous.

400
Rendered
Sonorous.

Lead yields the dullest and weakest sound of all metallic bodies. Reaumur observes, that it is rendered sonorous by casting a small quantity into a spherical or elliptical segment, as in the bottom of an iron-ladle: from hence he conjectures, that the sound of the sonorous metals might be improved for the bells of clocks, &c. by giving them a similar form.

Though this metal very soon loses its lustre, and tarnishes in the air, it resists much longer than iron or copper the combined action of air and water, before it is decomposed or destroyed; and hence it is exceedingly useful for many purposes to which these metals can by no means be applied. When just become fluid, lead looks bright like quicksilver; but immediately contracts a variously coloured pellicle on the surface. If this is taken off, and the fire continued, a fresh pellicle will always be formed, till the metal is by degrees changed into a dusky powder, or calx. The injection of a little fat, charcoal-powder, or other inflammable matter, prevents this change, and readily revives the calx into lead again. It is said, that lead, recovered from its cakes, proves somewhat harder and whiter than at first, as well as less subject to tarnish in the air.

402
Minium.

The blackish calx or ashes of lead become of a very different appearance if the calcination is continued with a fire so moderate as not to melt them, and particularly if exposed to flame. By this treatment, they become first yellow; and are then called *massicot*, or *yellow lead*. This colour becomes gradually more and more intense, till at last the calx is of a deep red; and then is called *minium*, or *red lead*.

The preparation of this substance, which is much used in painting, has become a trade by itself. It is made from lead calcined to a greyish powder by keeping it melted over the fire. This powder, ground in mills, is further calcined in a reverberatory furnace, under a low arch, and frequently stirred with an iron-rake, to prevent its running and melting into clots, and to expose a fresh surface to the air and flame. The calcination lasts two or three days. The increase of the weight by some is said to amount to $\frac{1}{3}$, by others, to no less than $\frac{1}{2}$ of the lead employed; and the lead recovered from the minium to be $\frac{1}{5}$ less than the original weight of the metal. If the minium be further calcined, the increase is no more, but the quantity of lead recoverable from the calx proves less in proportion to the vehemence and continuance of the calcination.

403
Litharge.

If, instead of keeping this calx in a continued moderate heat, it is suddenly fused, the matter then puts on a foliated appearance, and changes to a dull kind of brick-colour when powdered, and is then called *litharge*. Most of this substance is produced by refining silver with lead, (see REFINING); and is of two kinds, white, and red. These two are distinguished by the

names of *litharge of gold*, and *litharge of silver*. The most perfect is that called *litharge of gold*: the pale sort contains a considerable proportion of lead in its metallic state; and even the highest coloured litharge is seldom free from a little metallic lead, discoverable and separable by melting the mass in a crucible; when the lead subsides to the bottom.

Lead mingles in fusion with all the metals except iron, with which it refuses any degree of union as long as the lead preserves its metallic form. On continuing the fire, the lead, scorifying or calcining, absorbs the phlogistic principle of the iron, and consequently promotes the calcination of that metal; both being at length reduced to calces. The fusible calx of lead easily unites with the calx of iron, and both melt together into an opaque brown or blackish glass. Copper does not unite with melted lead, till the fire is raised so high as to make the lead smoke and boil, and of a bright red heat. Pieces of copper, now thrown in, soon dissolve and disappear in the lead: the mixture, when cold, is brittle, and of a granulated texture. The union of these two metals is remarkably slight. If a mixture of copper and lead is exposed to a fire no greater than that in which lead melts, the lead almost entirely runs off by itself; a separation, of which no other example is known. What little lead is retained in the pores of the copper, may be scorified, and melted out, by a fire considerably less than is sufficient to fuse copper. If any of the copper is carried off by the lead, it swims unmelted on the surface.

Gold and silver are both dissolved by lead in a slight red heat. They are both rendered extremely brittle by the minutest quantity of this metal; though lead is rendered more ductile by a small quantity of either of them. In cupellation, a portion of lead is retained by gold, but silver parts with it all. On the other hand, in its eliquation from copper, if the copper contains any of the precious metals, the silver will totally melt out with the lead, but the gold will not. The attraction of lead to copper, however slight, is greater than that of copper to iron: a mixture of copper and iron being boiled in melted lead, the copper is imbibed by the lead, and the iron thrown up to the top. Silver is in like manner imbibed from iron by lead; whilst tin, on the contrary, is imbibed from lead by iron. If two mixtures, one of lead and tin, and another of iron and silver, be melted together, the result will be two new combinations, one of the tin with the iron at the top, the other with the lead and silver at the bottom: how carefully soever the matter be stirred and mixed in fusion, the two compounds, when grown cold, are found distinct, so as to be parted with a blow.

This metal is soluble in alkaline lixivia and expressed oils. Plates of lead boiled in alkaline lixivia, have a small part dissolved, and a considerable quantity corroded; the solution stains hair black. Lead, fused with fixed alkaline salts, is in part corroded into a dark-coloured scoria, which partially dissolves in water. Expressed oils dissolve the calces of lead, by boiling, in such large quantities as to become thick and consistent: hence plasters, cements for water-works, paint for preserving nets, &c. Acids have a greater affinity

PRACTICE

PRACTICE

affinity with lead than oils have. If the common plaster, composed of oil and litharge, be boiled in distilled vinegar, the litharge will be dissolved, and the oil thrown up to the top. The oil thus recovered, proves soluble like essential oils in spirit of wine; a phenomenon first taken notice of by Mr Geoffroy.

6. TIN.

The colour of this metal resembles silver, but somewhat darker. It is softer, less elastic, and sonorous, than any other metal except lead. When bent backwards and forwards, it occasions a crackling sound, as if torn asunder. It is the lightest of all the malleable metals, being little more than seven times specifically heavier than water. The tenacity of its parts also is not very considerable; a tin wire of $\frac{1}{16}$ of an inch diameter, being able to support only 495 pounds.

406
Capable of
being beat
into thin
leaves.

Tin is commonly reckoned the least ductile of all metals except lead; and certainly is so, in regard to ductility into wire, but not in regard to extensibility into leaves. These two properties seem not to be so much connected with one another as is generally imagined. Iron and steel may be drawn into very fine wire, but cannot be beat into leaves. Tin, on the other hand, may be beat into very thin leaves, but cannot be drawn into wire; gold and silver possess both properties in a very eminent degree; whilst lead, notwithstanding its flexibility and softness, cannot be drawn into fine wire, or beat into thin leaves. It melts the most easily of all the metals; about the 430th degree of Fahrenheit's thermometer. Heated till almost ready to melt, it becomes so brittle that large blocks may be easily beat to pieces by a blow. The purer sort, from its facility of breaking into long shining pieces, is called *grain-tin*. Melted, and nimbly agitated at the instant of its beginning to congeal, it is reduced into small grains, or powder.

407
Calcin'd.

With the heat necessary for fusion, it may also be calcined; or at least so far deprived of its phlogiston as to appear in the form of a grey calx, which may be entirely reduced to tin by the addition of inflammable matter. The calcination of tin, like that of lead, begins by the melted metal losing its brightness, and contracting a pellicle on its surface. If the fire is raised to a cherry-red, the pellicle swells and bursts, discharging a small bright flame of an arsenical smell. By longer continuance in the fire, the metal is converted first into a greyish, and then into a perfectly white calx, called *putty*, which is used for polishing glasses, and other hard bodies.

The calx of tin is the most refractory of all others, that of platinum excepted. Even in the focus of a large burning mirror, it only softens a little, and forms crystalline filaments. With glasses of bismuth, and the simple and articulated glasses of lead, it forms opaque milky compounds. By this property it is fitted for making the basis of the imperfect glasses called *enamel*s; (see GLASS, and ENAMEL). The author of the Chemical Dictionary relates, that "having exposed very pure tin, singly, to a fire as strong as that of a glass-house furnace, during two hours, under a muffle, in an uncovered test; and having then examined it, the metal was found covered with an exceedingly white calx, which appeared to have formed a vegetation;

VOL. III.

under this matter was a reddish calx, and an hyacinthine glass; and lastly, at the bottom, was a piece of tin unaltered. The experiment was several times repeated with the same success."

Nitre deflagrates with tin, and hastens the calcination of this as well as of other imperfect metals. The vapours which rise from tin, by whatever method it is calcined, have generally an arsenical smell. Tin melted with arsenic falls in great part into a whitish calx: the part which remains uncalcined proves very brittle, appears of a white colour, and a sparkling plated texture, greatly resembling zinc. The arsenic is strongly retained by the tin, so as scarcely to be separable by any degree of fire; the tin always discovering, by its augmentation in weight, that it holds a portion of arsenic, though a very intense fire has been used. Hence, as the tin-ores abound in arsenic, the common tin is found also to participate of that mineral.

408
Affinity of
tin with
arsenic.

Henckel discovered a method of separating actual arsenic from tin; namely, by slowly dissolving the tin in eight times its quantity of an aqua regia made with sal ammoniac, and setting the solution to evaporate in a gentle warmth: the arsenic begins to concrete whilst the liquor continues hot, and more plentifully on its growing cold, into white crystals. Mr Margraaf, in the Berlin Memoirs for 1747, has given a more particular account of this process. He observes, that the white sediment which at first separates during the dissolution, is chiefly arsenical: that Malacca tin, which is accounted one of the purest sorts, yielded no less than $\frac{1}{2}$ its weight of arsenical crystals; that some sorts yielded more; but that tin extracted from a particular kind of ore which contained no arsenic, afforded none. That the crystals were truly arsenical, appeared from their being totally volatile; from their subliming (a little fixed alkaline salt being added to absorb the acid) into a colourless pellicid concrete; from the sublimate, laid on a heated copper-plate, exhaling in fumes of a garlic smell; from its staining the copper white; and from its forming with sulphur, a compound similar to the yellow or sulphurated arsenic. He found that the arsenic was separable also by means of mercury: an amalgam of tin being long triturated with water, and the powder which was washed off committed to distillation, a little mercury came over, and bright arsenical flowers arose in the neck of the retort. Dr Lewis observes, that the crackling noise of tin in bending may possibly arise from its arsenic; as those operations which are said to separate arsenic from the metal, likewise deprives it of this property.

410
Dr Lewis's
observation.

Tin may be alloyed, in all proportions, with all metals by fusion: but it absolutely destroys their ductility, and renders them brittle, as in bell-metal; whence this metal has obtained the name of *diabolus metallorum*. It is remarkable, that the most ductile metals are most injured by the addition of a small quantity of tin; the vapour of a single grain of tin being sufficient to destroy the ductility of a considerable quantity of gold.

411
Injurious to
other metals.

Iron is dissolved by tin in a heat far less than that in which iron itself melts: the compound is white and brittle. Iron added to a mixture of lead and tin, takes up the tin, leaving the lead at the bottom; and, in like manner,

11 F

manner,

PRACTICE manner, if lead, tin, and silver are melted together, the addition of iron will absorb all the tin, and the tin only. Hence an easy method of purifying silver from tin.

412 Not liable to rust. Tin, notwithstanding it is, like lead, soon deprived of its lustre by exposure to the air, is nevertheless much less liable to rust than either iron, copper, or lead; and hence is advantageously used for covering over the infides of other metalline vessels. The amalgam of mercury and tin is employed to cover one of the surfaces of looking-glasses; by which they are rendered capable of reflecting the rays of light. The amalgam also, mixed with sulphur and sal ammoniac, and set to sublime, yields a sparkling gold-coloured substance called *aurum mosaicum*; which is sometimes used as a pigment. This preparation is commonly made from quicksilver and tin, of each two parts, amalgamated together, and then thoroughly mixed with sulphur and sal ammoniac, of each one part and a half. The mercury and sulphur unite into a cinabar, which sublimes along with the sal ammoniac; and, after sublimation, the aurum mosaicum remains at the bottom.

Sulphur may be united with tin by fusion; and forms with it a brittle mass, more difficultly fusible than pure tin. Sulphur has, in this respect, the same effect upon tin, as upon lead. The alloy of tin lessens the fusibility of these very fusible metals; while it increases the fusibility of other difficultly fusible metals, as iron and copper.

7. MERCURY, or QUICKSILVER.

Mercury is a fluid metallic substance, of a bright silver colour, resembling lead or tin when melted; entirely void of taste and smell; extremely divisible; and congeals into a degree of cold very difficultly produced, in this country, by art, (see **COLD**, and **CONGELATION**). It is the most ponderous of all fluids, and of all known bodies, gold and platinum excepted; its specific gravity being to that of water nearly as 14 to 1. It is found to be specifically heavier in winter than in summer, by 25 grains in 11 ounces.

Neither air nor water, nor the united action of these two, seem to make any impression upon mercury: nor is it more susceptible of rust than the perfect metals. Its surface, nevertheless, is more quickly tarnished than gold or silver; because the dust which floats in the air, quickly seizes on its surface. The watery vapours also, which float in the air, seem to be attracted by mercury.

415 Purification. From these extraneous matters, which only slightly adhere to it, mercury may be easily cleaned by passing it through a clean new cloth, and afterwards heating it: but if mixed with any other metal, no separation can be effected without distillation. In this process, a small portion of some of the metals generally arises along with the mercury. Thus, quicksilver distilled from lead, bismuth, or tin, appears less bright than before; stains paper black; sometimes exhibits a skin upon the surface; and does not run freely, or into round globules. Mr Boyle relates, that he has observed the weight of mercury sensibly increased by distillation from lead, and this when even a very moderate fire was made use of. By amalgamation

PRACTICE with stellated regulus of antimony, and then being distilled after a few hours digestion, mercury is said to become, by a few repetitions of the process, more ponderous, and more active: the animated, or philosophic mercuries of some of the alchemists, are supposed to have been mercury thus prepared. By the same, or similar processes, seem to have been obtained the curious mercuries which Boyle declared he was possessed of, and made himself; which were "considerably heavier in specie than common quicksilver,—dissolved gold more readily,—grew hot with gold, so as to be offensive to the hand, and elevated gold in distillation." When quicksilver is to be distilled, it is proper to mingle it with a quantity of iron-filings; which have the property of making it much brighter than it can be otherwise obtained, probably by furnishing phlogiton.

By digestion in a strong heat for several months, mercury undergoes a considerable alteration, changing into a powder, at first ashr-coloured, afterwards yellow, at length of a bright-red colour, and an acrid taste; and is then called *mercurius precipitatus per se*. In this last state it proves similar to the red precipitate, prepared from a solution of mercury in nitrous acid; the nitrous acid in the air seeming to be revived into its proper form, by long contact with the metal, (see **AIR**, n° 44). This calx proves less volatile in the fire than the mercury in its fluid state. It supports, for some time, even a degree of red heat. In the focus of a burning-glass, it is said, if laid upon a tile, to vitrify on a piece of charcoal, and to revive into running mercury before it exhales. Evaporated by common fire, it leaves a small portion of a light brown powder; which, Boerhaave relates, bore a blast-heat; swelled into a spongy mass; formed with borax a vitreous friable substance; but vanished in cupellation. By long continued digestion in a gentle heat, mercury suffers little change. Boerhaave digested it in low degrees of heat, both in open and close vessels, for 15 years together, without obtaining any other reward for his labour than a small quantity of black powder; which, by trituration, was quickly revived into running mercury. Constant triture, or agitation, produce a change similar to this, in a short time. Both the black and red powders, by bare exposure to a fire sufficient to elevate them, return into fluid mercury. The red powder has been revived by simply grinding it in a glass-mortar.

In like manner, quicksilver remains unchanged by distillation. Boerhaave had the patience to distil 18 ounces of mercury upwards of 500 times over, without observing any other change than that its fluidity and specific gravity were a little increased, and that some grains of a fixed matter remained. The vapours of mercury, like those of all other volatile bodies, cause violent explosions if confined. Mr Hellot gives an account of his being present at an experiment of this kind: a person pretending to fix mercury, had inclosed it in an iron box closely welded. When the mercury was heated, it burst the box, and dissipated in invisible vapours.

Mercury dissolves or unites with all metallic bodies, except three, *viz.* iron, arsenic, and nickel: in some cases it will absorb metals, particularly gold and silver, from

420 Explosion by the vapours of mercury.

421 Amalgamated with different substances.

PRACTICE from their solution[†] in acids or alkalies; but does not act upon any metal when combined with sulphur, nor on precipitates made by alkalies, nor on calces by fire. Whatever metal it is united with, it constantly preserves its own white colour. It unites with any proportion of those metallic substances with which it is capable of being combined; forming, with different quantities, amalgams of different degrees of consistence. From the fluid ones, greatest part of the quicksilver may be separated by colature. Bismuth is so far attenuated by mercury, as to pass through leather with it in considerable quantity. It also promotes the action of quicksilver upon lead to a great degree; so that mercury united with $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ its weight of bismuth, dissolves masses of lead in a gentle warmth, without the agitation, triture, comminution, or melting heat necessary to unite pure mercury with lead. From these properties, this solution of bismuth in mercury becomes a proper solvent for pieces of lead lodged in the human body.

422
Separation of the amalgamated metal.

On triturating or digesting amalgams for a length of time, a blackish or dusky-coloured powder arises to the surface, and may be readily washed off by water. Some of the chemists have imagined, that the amalgamated metal was here reduced to its constituent parts: but pure mercury is by itself reducible to a powder of the same kind; and the metallic particles in this process, united with the mercury, are found to be no other than the metal in its entire substance. Some metals separate more difficultly than others; gold and silver the most so. Boerhaave relates, that if the powder which separates from an amalgam of lead be committed to distillation with vinegar in a tall vessel, the mercury will rise before the vinegar boils: that, by a like artifice, quicksilver may be made to distil in a less degree of heat than that of the human body; but Dr Lewis, though he made many trials, was never able to succeed.

423
Becomes fixed by amalgamation with gold.

By amalgamation with gold, mercury may become exceedingly fixed; so as not to be dissolvable by the greatest heat. Concerning this, Dr Brandt relates the following curious experiment: "Having amalgamated fine gold with a large proportion of quicksilver, and strained off the superfluous mercury, he digested the amalgam in a close stopp'd vessel for two months with such a degree of heat, that a part of the quicksilver sublimed into the neck of the glass. The matter being then ground with twice its weight of sulphur, and urged with a gradual fire in a crucible, a spongy calx remained; which being melted with borax, and afterwards kept in fusion by itself for half an hour, in a very violent fire, still retained so much of the quicksilver, as to become brittle under the hammer, and appear internally of a leaden colour. The metal being again amalgamated with fresh mercury, the amalgam again ground with sulphur, and exposed to an intense fire, a spongy calx remained as before. This calx being digested in two or three fresh parcels of aqua regia, a small portion of whitish matter remained at last undissolved. The paper which covered the cylindrical glass wherein the digestion was performed, contracted, from the vapours, a deep-green circular spot in the middle, with a smaller one at the side; whereas the aqua regia digested in the same manner

by itself, or with gold, or with mercury, gave no stain. The first solution, on the addition of oil of tartar *per deliquium*, grew red as blood; on standing, it deposited, first, a little yellow calx, like aurum fulminans; afterwards, a bright matter like fine gold; and at last, a paler precipitate, inclining to green; its own deep red colour and transparency remaining unchanged. Being now committed to distillation, a colourless liquor arose; and the residuum, perfectly exsiccated, yielded, on edulcoration, a yellow calx of gold; which the alkaline lixivium had been unable to precipitate. The second solution turned green on the admixture of the alkaline liquor, and let fall a white precipitate, which turned black and brown. The several precipitates were calcined with twice their weight of sulphur, and then melted with four times their quantity of flint, and twelve of pot-ash, in a fire vehemently excited by bellows. The scoria appeared of a golden colour, which on pulverization and edulcoration, vanished. At the bottom was a regulus, which looked bright like the purest gold; but was not perfectly malleable. Broke, it appeared internally white; and the white part amounted to at least one-third its bulk. Besides this lump of metal, there were several others, white like silver, and soft as lead."

424
Supposed to be convertible into water.

In Wilson's chemistry, we have a process for converting quicksilver into water, by dropping it by little and little into a tall iron vessel, heated almost to a white heat in the bottom. Over the mouth of this vessel were luted seven aludels; and on the top, a glass alembic head, with a beak, to which was fitted a receiver. The mercury was put in so slowly, that it required 16 hours for one pound. Every time that a little quantity of mercury was put in, it made a great noise, filling the aludel's head, and receiver, with white fumes. When the vessels were cooled, a little water was found in each of the receivers; and in the first and second, some grains of crude mercury. The whole quantity amounted to 13 ounces and 6 drachms; which was expected to prove a powerful solvent of gold and silver: but, on trial, was found to be in no respect different from common water. On this experiment, Dr Lewis has the following note.

"The possibility of converting mercury into water, or at least of obtaining a great quantity of water from mercury, has not only been believed by several great men in the chemical art; but some have even ventured to assert that they have actually made this change. Yet nevertheless, they have delivered the history of this affair with such marks, as seem to make the reality of the change extremely doubtful. Mr Boyle, (in his tract of the *production of Chemical Principles*, annexed to *Scept. Chemist.* p. 235), says, "that he once obtained water from mercury without addition, without being able to make the like experiment succeed afterwards." Mr Le Febvre, who is generally looked upon as an honest practitioner, directs a process similar to that above (Wilson's), for obtaining of this mercurial water. But it is to be suspected, as Mr Hales very well observes (in his *Statical Experiments*, p. 200.), that Mr Boyle, and others, were deceived by some unheeded circumstance, when they thought they obtained a water from mercury, which should seem rather to have arisen from the lute

425
Dr Lewis's detection of the fallacy of this process.

PRACTICE

PRACTICE

and earthen vessels made use of in the distillation : for Mr Hales could not find the least sign of any moisture upon distilling mercury in a retort made of an iron gun-barrel, with an intense degree of heat ; although he frequently cohobated the mercury which came over into the recipient. In a course of chemical experiments, I repeated Mr Hales's process, and urged the mercury, which was let fall by little and little, through an aperture made in the gun-barrel, with a moist intense degree of heat, without obtaining any water ; but it being suspected by a bystander, that the mercury in this experiment came over before it had been sufficiently acted upon by the fire, by reason of the lowness of the neck of the distilling instrument, the experiment was varied in the following manner. Sixteen ounces of mercury were heated in a crucible, in order to evaporate any moisture that might have been accidentally mixed with it ; and an iron gun-barrel of four feet in length, being placed perpendicularly in a good furnace, and a glass-head and recipient fitted to its upper part, the mercury was let fall by little and little into the barrel, and the fire urged with bellows. After each injection, the mercury made a considerable noise and ebullition, and arose into the head ; where it soon condensed and trickled down, in the common form of running mercury, into the recipient, without the least perceptible appearance of any aqueous humidity."

426
How to amalgamate with regulus of antimony.

Mercury is difficultly amalgamated with regulus of antimony and copper ; for which some particular manœuvres are required. Two of Dr Lewis's receipts for uniting quicksilver with copper, we have already given, (see n^o 376) : with regulus of antimony, mercury, he says, may be perfectly united, by pouring a small stream of melted regulus into a considerable portion of mercury, made almost boiling hot. Another method directed by Henckel, is to put mercury into an iron mortar along with some water, and set the whole over the fire. When the water boils, a third or fourth part of melted regulus is to be poured in, and the mass ground with a pestle, till the amalgama is completed. The use of the water, as Dr Lewis observes, is to hinder the mercury from flying off by the heat of the regulus : but as the two are by this means not put together in so hot a state, the union is more difficult, and less perfect. The loss of the mercury, in the first process, may be prevented by using a large vessel, and covering it with a perforated iron-plate, through the hole in which the regulus is to be poured. This method is likewise applicable to the amalgamation of copper.

With sulphur, mercury unites very readily, forming by trituration, or simple fusion, a black powder, or mass, called *Ethiops mineral* ; which, by careful sublimation, becomes the beautiful red pigment called *vermilion*. (See SULPHUR, sect. iv.)

8. ZINC.

This is a semi-metal of a bluish white colour. It is the least brittle of any of the semi-metals ; and when amply supplied with phlogiston, which may be done by treating it in close vessels with inflammable matters, it possesses a semi-ductility, by which it may be flattened into thin plates. When broken, it appears

of many flat shining plates or facets, which are larger when slowly than when hastily cooled. When heated, it is very brittle ; and crackles like tin, only louder, when bent. Exposed to the air, it contracts in length of time a yellowish ruit. Its specific gravity, according to Dr Lewis, is to that of water as $7\frac{1}{10}$ to 1. It begins to melt as soon as red hot ; but does not flow thin till the fire is raised to a white heat. Then the zinc immediately begins to burn with an exceedingly bright and beautiful flame. Kept just in in fusion, it calcines slowly ; not only on the upper surface, but likewise round the sides, and at the bottom of the crucible. If several pieces are just melted together, the mass, when grown cold, may be broke into the same number ; their union being prevented by a yellowish calx, with which each piece is covered over. Mr Malouin relates, in the French Memoirs for 1742, that a quantity of zinc being melted six times, and the fusion continued fifteen hours each time, it proved, on every repetition, harder, more brittle, less fusible, and less calcinable : that after the two first fusions, its colour was grey ; after the third, brown ; and after the fourth, black : that the fifth rendered it of a slate-blue ; and the sixth of a clear violet.

So violent is the deflagration of zinc, that the whole of its calx is sublimed by it, in the form of light flocks, or wool ; which, however, are easily reduced to a fine powder. These are used in medicine, and reckoned an excellent remedy in epileptic cases. When once sublimed, they are by no means capable of being elevated again by the most violent heat. In a heat far greater than that in which they first arose, they suffer no alteration ; in a very vehement one they melt, according to Henckel, into a semi-opaque green glass. Vitrified with borax, they give a grey, or brownish, glass. From the brightness of the flame of burning zinc, and the garlick-smell which it is said to emit, some have concluded that zinc contained the phosphoric acid ; which, from some other circumstances, is not altogether improbable.

The flowers of zinc have been thought very difficultly, or not at all, reducible to their metallic form by an addition of phlogiston. But Dr Lewis observes, that this difficulty proceeds not from their unfitness to be restored into the form of zinc, but from the volatility of the semi-metal, which occasions its being dissipated in fumes, if the common methods are made use of. All cakes, those of iron excepted, require a greater heat for their fusion than that in which the metal itself melts ; and as a full melting heat is the greatest that zinc can sustain, it burns and calcines the instant of its revival, if the air is admitted ; and in close vessels escapes, in part at least, through their pores. On mixing flowers of zinc with powdered charcoal, and urging them with a strong fire in a crucible, a deflagration and fresh sublimation ensue ; sufficient marks that the zinc has been reduced to its metallic form ; for as long as it remains in the state of calx, neither of these effects can happen. If the vessel is so contrived as to exclude the air, and at the same to allow the reviving semi-metal to run off from the vehemence of the heat, into a receiver kept cool, the zinc will there concrete, and be preserved in its metallic state.

427
Deflagration.

428
Flowers of zinc.

429
Dr Lewis's method of reducing them.

PRACTICE

It is still more effectually detained by certain metallic bodies, as copper, or iron; with which the zinc, when thus applied, unites more readily and perfectly than it can be made to do by any other means.

430
Oil from
flowers of
zinc by Mr
Homberg.

Homberg pretended to obtain an oil from the flowers of zinc, by dissolving them in distilled vinegar, and then distilling the solution in a glass retort. At first a quantity of phlegm arose; then the superfluous acid; and at last an empyreumatic oil. This last, which Homberg imagined to proceed from the flowers of zinc, Neuman very justly attributes to the distilled vinegar.

431
Another by
Mr Heliot.

An oil of another kind was obtained by Mr Heliot from the above solution, by digesting the ash-coloured residuum, which remained after the distillation with the acidulous phlegm which came over, for eight or ten days; distilling the tincture to dryness; and repeating the extraction with the distilled liquor, till the quantity of dry extract, thus obtained, was very considerable. This resin-like matter, distilled in a retort with a stronger fire, yielded a yellowish liquor, and a white sublimate. The liquor discovered no mark of oil; but, upon being passed upon the sublimate, immediately dissolved it, and then exhibited on the surface several drops of a reddish oil. Some of this oil was taken up on the point of a pencil, and applied to gold and silver-leaf. In twenty-four hours, the parts touched appeared, in both, equally dissolved.

432
Zinc with
other me-
tals.

Zinc does not unite in fusion with bismuth, or the semi-metal called *nickel*. It unites difficultly with iron; less so with copper; easily with the other metals. It renders iron or copper more easily fusible; and, like itself, brittle whilst hot, though considerably malleable when cold. It brightens the colour of iron almost into a silver lue, and changes that of copper into a yellow or gold colour. It greatly debases the colour of gold; and renders near an hundred parts of that most ductile metal brittle and intractable. A mixture of equal parts of each is very hard, white, and bears a fine polish; hence it is proposed by Mr Heliot for making specula. It is not subject to rust or tarnish in the air, like those metals whose basis is copper. It improves the colour and lustre of lead and tin, renders them firmer, and consequently fitter for several mechanic uses. Tin, with a small proportion of zinc, forms a kind of pewter. Lead will bear an equal weight, without losing too much of its malleability. Malouin observes, that arsenic, which whitens all other metals, renders zinc black and friable; that when the mixture is performed in close vessels, an agreeable aromatic odour is perceived on opening them; that zinc amalgamated with mercury, and afterwards recovered, proves whiter, harder, and more brittle than before, and no longer crackles on being bent.

441
Deflagra-
tion of zinc
with other
metals.

Mixtures of zinc with other metals, exposed to a strong fire, boil and deflagrate more violently than zinc by itself. Some globules of the mixture are usually thrown off during the ebullition, and some part of the metal calcined and volatilized by the burning zinc: hence this substance has been called *metallic nitre*. Gold itself does not entirely resist its action. It very difficultly volatilizes copper; and hence the sublimates obtained in the furnaces where brass is made, or mixtures of copper and zinc melted, are rarely found to

participate of that metal. On melting copper and zinc separately, and then pouring them together, a violent detonation immediately ensued, and above half the mixture was thrown about in globules.

Zinc does not unite in the least with sulphur, or with crude antimony, which scorify all other substances except gold and platina; nor with compositions of sulphur and fixed alkaline salts, which dissolve gold itself. With nitre it deflagrates violently. Its flowers do not sensibly deflagrate; yet alkalize double their weight of the salt, more readily than the zinc itself. The alkaline mass appears externally greenish, internally of a purple colour. It communicates a fine purple to watery, and a red to vinegar. The acceus tincture inspissated, leaves a tenacious substance which soon runs in the air into a dark red caustic liquor, the alkalic of some of the pretended deaups.

lized by
flowers of
zinc.

9. BISMUTH.

This semi-metal, called also *tin-glass*, and by some naturalists *marcasita officinarum*, is somewhat similar to the regulus of antimony. It appears to be composed of cubes formed by the application of plates upon each other. Its colour is less white than that of regulus of antimony; and has a reddish tinge, particularly when it is exposed to the air. In specific gravity it approaches to silver; being nearly ten times heavier than water. It has no degree of malleability; breaking under the hammer, and being reducible by trituration to fine powder. Its melts a little later than tin, and seems to flow the thinnest of all metallic substances. Bismuth is semi-volatile, like all other semi-metals. When exposed to the fire, flowers rise from it; it is calcined; and converted into a litharge and glass nearly as lead is: (See GLASS.) It may even be employed like that metal, in the purification of gold and silver by cupellation. (See REFINING.) When in fusion it occupies less volume than in its solid state: a property peculiar to iron among the metals, and bismuth among the semi-metals. It emits fumes in the fire as long as it preserves its metallic form; when calcined or vitrified, it proves perfectly fixed.

447
Convertible
into
litharge
and glass.

Bismuth mingles in fusion with all the metalline substances, except regulus of cobalt and zinc. The addition of nickel, or regulus of antimony, renders it miscible with the former, though not with the latter. It greatly promotes the tenacity as well as facility of the fusion of all those metals with which it unites. It whitens copper and gold, and improves the colour of some of the white metals: mixed in considerable quantity, it renders them all brittle, and of a flaky structure like its own. If mixed with gold, or silver, a heat that is but just sufficient to melt the mixture, will presently vitrify a part of the bismuth; which, having then no action on those perfect metals, separates, and glazes the crucible all round.

metals.

10. REGULUS OF ANTIMONY.

This semi-metal, when pure, and well fused, is of a white shining colour, and consists of laminae applied to each other. When it has been well melted, and not too hastily cooled, and its surface is not touched by any hard body during the cooling, it exhibits the perfect

449
Appear-
ance of a
flor on its
surface.

PRACTICE perfect figure of a star, consisting of many radii issuing from a center. This proceeds from the disposition that the parts of this semi-metal have to arrange themselves in a regular manner, and is similar to the crystallization of salts.

Regulus of antimony is moderately hard; but, like other semi-metals, it has no ductility, and breaks in small pieces under a hammer. It loses $\frac{1}{2}$ of its weight in water. The action of air and water destroys its lustre, but does not rust it so effectually as iron or copper. It is fusible with a heat sufficient to make it red hot; but when heated to a certain degree, it fumes continually, and is dissipated in vapours. These fumes form what are called the *argentine flowers* of regulus of antimony, and are nothing but the earth of this semi-metal deprived of part of its inflammable principle, and capable of being reduced to its reguline state by an union with this principle.

450
Sublimable.

451
Separation of the sulphur from antimony.

There are different methods of preparing the regulus of antimony; but all of them consist merely in separating the sulphur which this mineral contains, and which is united with the regulus. It is plain, therefore, that regulus of antimony may be made by an addition of any substance, to crude antimony in fusion, which has a greater attraction for sulphur than the regulus itself has. For this purpose, alkaline salts have been employed, either previously prepared, or extemporaneously produced in the process, by a defflagration of tartar and nitre. By this means, the sulphur was indeed absorbed; but the hepar sulphuris, formed by the union of the sulphur and alkali, immediately dissolved the regulus, so that very little, sometimes none at all, was to be obtained distinct from the scoria. Metals are found to answer better than alkaline salts, but the regulus is seldom or never free from a mixture of the metal employed. The way of obtaining a very pure regulus, and in great quantity, is to calcine the antimony in order to dissipate its sulphur; then to mix the calx with inflammable matters, such as oil, soft soap, &c. which are capable of restoring the principle of inflammability to it. This method was invented by Kunkel. Another, but more expensive way of procuring a large yield of very pure regulus, is, by digesting antimony in aqua regis, which dissolves the reguline part, leaving the sulphur untouched, precipitating the solution, and afterwards reviving the precipitate by melting it with inflammable matters.

452
Regulus easily miscible with mercury.

There are considerable differences observed in the regulus of antimony, according to the different substances made use of to absorb the sulphur. When prepared by the common methods, it is found to be very difficultly amalgamated with mercury, (see n° 426); but Mr Pott has discovered, that a regulus prepared with two, or five parts of iron, four of antimony, and one of chalk, yield reguli which readily unite with mercury into an hard amalgam, by bare trituration with water. Marble and quicklime succeed equally well with chalk; but clay, gypsum, or other earths, have no effect.

453
Extemporaneously miscible with cawk.

One earthy substance, found in lead-mines, and commonly called *cawk*, has a very remarkable effect upon antimony. This is found in whitish, moderately compact, and ponderous masses: it is commonly supposed

a spar; but differs from bodies of this kind, in not being acted upon by acids. If a lump of cawk, of an ounce or two, be thrown red hot into 16 ounces of melted antimony, the fusion continued about two minutes, and the fluid matter poured off, "you will have 15 ounces like polished steel, and as the most refined quicksilver." *Phil. Transf.* n° 110. Dr Lewis mentions his having repeated this experiment several times with success: but having once varied it by mixing the cawk and antimony together at the first, a part of the antimony was converted into a very dark black vitreous matter, and part seemed to have suffered little change; on the surface of the mass some yellow flowers appeared. Neither the nature of cawk, nor of the change produced on antimony by it, has been hitherto well considered.

Regulus of antimony enters into the compositions for metallic speculums for telescopes, and for printing-types. It is also the basis of many medicinal preparations; but many of these, which were formerly much esteemed, are found to be either inert, uncertain, or dangerous in their operation. When taken in substance, it is emetic and purgative, but uncertain in its operation; because it only acts in proportion to the quantity of solvent matter it meets with in the stomach; and if it meets with nothing capable of acting upon it there, the regulus will be quite inactive. For these reasons, the only two preparations of antimony now retained, at least by skilful practitioners, are the infusion of glass of antimony in wine, and emetic tartar. For making the glass of antimony we have the following process. "Take a pound of antimony; reduce it to fine powder, and let it over a gentle fire; calcine it in an unglazed earthen pan, till it comes to be of an ash colour, and ceases to fume: you must keep it continually stirring; and if it should run into lumps, you must powder them again, and then proceed to finish the calcination. When that is done, put the calcined antimony into a crucible; set it upon a tile in a wind-furnace; put a thin tile on the top; and cover it all over with coals. When it is brought into fusion, keep it so in a strong fire for an hour: then put into it an iron rod; and when the melted antimony, which adheres to it, is transparent, pour it upon a smooth, hot, marble; and when it is cold, put it up for use. This is *vitrum antimonii*, or *sibiium*."

454
Glass of antimony.

This preparation is more violent in its effects than the pure regulus itself; because it contains less phlogiston, consequently is similar to a regulus partially calcined, and so more soluble. Hence it is the most proper for infusion in wine, or for making the tartar emetic. It is obviously, however, liable to great uncertainties in point of strength; for as the antimony is more or less strongly calcined, the glass will turn out stronger or weaker in its operation, and consequently all the preparations of it must be liable to much uncertainty. This uncertainty is very apparent in the strength of different parcels of emetic tartar: accordingly Mr Geoffroy found by examination of different emetic tartars, that an ounce of the weakest contained from 30 to 90 grains of regulus; an ounce of moderate strength contained about 108 grains; and an ounce of the strongest kind contained 154 grains. For these reasons, the author of the Chemical

miscal

PRACTICE

456
Pulvis algaroth the most proper material for emetic tartar.

mical Dictionary recommends the pulvis algaroth, (n° 258.) as the most proper material for making emetic tartar; being perfectly soluble, and always of an equal degree of strength. Emetic tartar, as he justly observes, ought to be a metallic salt composed of cream of tartar saturated with the regulus of antimony; and Mr Beaumé has shewn such a saturation to be possible, and that the neutral salt crystallizes in the form of pyramids. They are transparent while moist; but by exposure to a dry air, they lose the water of their crystallization, and become opaque. The preparation of this salt, according to Mr Beaumé, consists in mixing together equal parts of cream of tartar, and levigated glass of antimony: these are to be thrown gradually into boiling water; and the boiling continued, till there is no longer any effervescence, and the acid is entirely saturated. The liquor is to be filtered; and upon the filter is observed a certain quantity of sulphureous matter, along with some undissolved parts of the glass of antimony. When the filtered liquor is cooled, fine crystals will be formed in it, which are a soluble tartar perfectly saturated with glass of antimony. He observes, that the dissolution is soon over if the glass is well levigated, but requires a long time if it is only grossly powdered.

457
Objection to its use.

The trouble of levigating glass of antimony, as well as the uncertainty of dissolving it, would render *pulvis algaroth* much preferable, were it not on account of its price; which would be a temptation to those in use to prepare medicines, to substitute a cheaper antimonial preparation in its place.

As regulus of antimony, like other metallic substances, is soluble in liver of sulphur, it happens, that, on boiling antimony in an alkaline ley, the salt, uniting with the sulphur contained in that mineral, forms an hepar sulphuris, which dissolves some of the reguline part. If the liquor is filtered, and saturated with an acid, the regulus and sulphur will fall together in form of a yellowish or reddish powder, called *golden sulphur of antimony*. If the ley is suffered to cool, a like precipitation of a red powder happens. This salt is called *kermes mineral*.

458
Diaphoretic antimony.

Nitre deflagrates violently with antimony, consuming not only its sulphureous part, but also the phlogiston of the regulus; and thus reduces the whole to an inert calx, called *antimonium diaphoreticum*. If equal parts of nitre and antimony are deflagrated together, the sulphureous part is consumed, as well as part of the inflammable principle of the regulus. The metalline part melts, and forms a semi-vitreous mass, of a reddish colour, called *crocus metallorum*, or *liver of antimony*. It is a violent emetic, and was formerly used for making infusions in wine similar to those of glass of antimony; but is now disused on account of its uncertainty in strength. It is still used by the farriers; but the substance sold for it is prepared with a far less proportion of nitre; and sometimes even without any alkaline salt being added to absorb part of the antimonial sulphur. This *crocus* is of a dull red colour; and when powdered, assumes a dark purple.

II. ARSENIC.

This mineral, when in its pure state, has no appearance of a metallic substance. It is moderately heavy,

compact, brittle, and of a crystalline and vitreous appearance. Exposed to the air, it changes to a milky hue like that of porcelain; and at length to the opaque whiteness of white enamel. The larger masses preserve their transparency longer than the small, and longer in a dry than in a moist air. In the fire it totally exhales before melting, with a strong smell of garlic. The fumes, caught in proper vessels, condense either into a white powder, or into crystalline masses, as the receiver is more or less removed from the fire.

Arsenic easily unites with all metals and semi-metals, all of which it renders brittle. It renders gold of a greyish colour in its broken surface; silver, of a deep grey; and copper, white. Tin becomes, by mixture with arsenic, much harder, and more unfusible; lead becomes hard and very brittle; and iron is changed into a blackish mass. It volatilizes, vitrifies, and scorifies, all solid bodies; gold, silver, and platinum, excepted.

We have already taken notice (n° 183.) that arsenic is capable of decomposing nitre, and uniting with its basis. It then forms a singular sort of salt which cannot be decomposed by any acid; because the arsenic, when deprived of phlogiston, (which it perfectly is by the decomposition of the nitre,) seems to have a greater attraction for alkalis than acids have. Was it possible therefore to deprive arsenic of all its phlogiston, we should no doubt find it capable of expelling the marine, or vitriolic, as well as the nitrous acid. It readily unites with alkaline salts, in the common way of fusion: but is then easily separable by an acid; because, not being deprived of its phlogiston, the union between it and the alkali is very weak. This neutral arsenical salt may itself be decomposed, by melting it with inflammable matters, or adding a solution of it to any metallic solution. A double decomposition and combination then take place; the acid unites with the alkali, and the arsenic with the metal. Concerning the uses of this neutral salt, we find the following paragraph in the Chemical Dictionary.

“The uses of the neutral arsenical salt are not yet well determined; yet, as the arsenic seems to be strictly combined with the fixed alkali, this salt may probably be usefully employed, 1. For the preparation of regulus of arsenic. 2. To combine arsenic conveniently with metallic matters. 3. In the composition of many glasses. 4. As the corrosive mineral acids, when saturated with fixed alkali, form very mild salts, we may be induced to believe that arsenic completely saturated with a fixed alkali, as it is in the neutral arsenical salt, might form a very mild salt, which may be powerful in medicine; but the name of arsenic is so terrible, that it will probably never be tried: but if it should, very numerous and long trials ought previously to be made on animals.

“This salt might probably be useful in arts; for Mr Beaumé prepares large quantities of it for different manufactures; but the uses to which it is applied are kept a secret.”

In his prediction, however, our author has been mistaken; for a treatise has appeared, recommending, not the neutral arsenical salt, or any milder preparation of this substance, but pure white arsenic itself, as a specific in cancers. This treatise is published

by M. le Febvre, a French physician, who directs the arsenic to be taken in the following manner: "Take four grains * of arsenic, of a clear, white, shining appearance, and in small crystals; dissolve it by boiling in a pint † of distilled water; let the patient take a table spoonful of this solution, with an equal quantity of milk, and half an ounce of syrup of poppies, every morning fasting, and taking care to taste nothing for an hour after. This course must be continued for eight days, after which a dose is to be taken in the same manner twice every day; the first in the morning, the second towards eight at night. At the end of a fortnight three doses are to be given in a day, the third being taken at mid-day.

"In this manner women of a weakly constitution may continue till the cure is completed. But, with an adult of a good constitution, the dose may be augmented, by degrees, every eight days, till he take six spoonfuls of the solution every day; two table-spoonfuls being taken for each dose, with as much milk, and half an ounce of syrup of poppies. For children, tea-spoons must be used; and the dose should, on no account, exceed three of these, with a proportional quantity of syrup of poppies.

"But besides that the solution of arsenic is thus to be increased to a certain height, in point of quantity, the strength is also to be augmented. Six grains of arsenic may be dissolved in the second bottle of the solution, and eight in the third. But beyond this, our author thinks it unadvisable to proceed. He has, in general, found six bottles of the solution sufficient for the cure of an open cancer. In one case, however, eight were necessary.

"He informs us, that this remedy, taken with the above precautions, never occasions any unlucky accident; and is not disagreeable to the taste. It does not act in any certain manner upon the secretions or excretions. Some, indeed, discharge their urine more freely than usual; with some the belly is more loose; and with others the perspiration is more copious; but these effects are neither general nor constant.

"A purgative compounded of manna, rhubarb, and sal seignette, is to be given every eight or twelve days. Whey, with twelve grains of nitre to the bottle, or a weak decoction of the root of althea, with an equal quantity of nitre, is to be used for common drink. With respect to regimen, it is necessary to abstain from wine and fermented liquors. Broth made with a little veal, beef, or chicken, &c. are proper.

"M. le Febvre has sometimes been obliged to give the Peruvian bark, and to open an issue, when the humours were either very alkaline, or in very great quantity. He even considers an issue as useful in every case.

"Besides this treatment by internal medicines, he recommends, that the tumour, if not ulcerated, should be washed with a solution of arsenic, in the proportion of eight grains to a pint; and he advises the following cataplasm. Take of carrot-juice, one pound; of sugar of lead, half an ounce; of arsenic, dissolved in distilled vinegar, half an ounce; of liquid laudanum,

a drachm and an half: form the whole into a mass, with as much powder of hemlock as is necessary. With part of this cataplasm the tumour is to be covered to a tolerable thickness, and the whole kept on with a diachylon plaster.

"If the cancer is of the ulcerated kind, he advises that the ichorous serosity be taken away at each dressing, by means of dry *chapee*. He then directs the ulcer to be fomented with the arsenical solution, having the chillee taken off it, and having about a third part of red wine added to it. If the sore is of a very bad kind, he proposes that the arsenic be dissolved in a decoction of bark, for fomenting the ulcer. After this, the cataplasm mentioned above, and the plaster, are to be applied. This treatment must be renewed every twelve hours.

"Mr le Febvre, before he concludes this treatise, assures his readers, that, in more than two hundred instances, he has had proofs of the efficacy of the medicine here proposed. He does not, however, pretend that it is infallible in every case. He considers the disease to be incurable, if, in its progress, a considerable hemorrhage has happened, from the erosion of large blood-vessels; also when it attacks hæmorrhoidal or phthical patients. To judge of the efficacy of any remedy, he observes, that the patient with whom it is tried should at least enjoy an ordinary good constitution, and be free from a complication of diseases. And he considers the exhibition of a new remedy to a patient, in some measure, breathing his last, as serving no other purpose but to bring it into discredit." *Edin. Med. Comment.* vol. IV. p. 56,—61.

Whatever good effects arsenic may produce when given in this way, certain it is, that this substance is, of all others, the most poisonous, and most certainly fatal, if taken into the human body, even in a small quantity. It seems to act not only upon the stomach and intestines, but to produce also a very great tendency to dissolution in the blood itself; for those who die poisoned with arsenic, are generally covered over with red or purple spots. When arsenic is swallowed, a nausea, sickness, and reaching, commonly ensue in about half an hour. These are followed by violent vomitings, hiccups, and pains in the stomach and bowels. Convulsions and palsies of the limbs presently succeed, with intense heats, cold sweats, palpitations of the heart, extreme anxiety, restlessness, prostration of strength, thirst, and dryness of the mouth and throat, loss of reason, and at last death. If the quantity taken was considerable, the patient dies in seven or eight hours after taking it; and the stomach and intestines are found, upon dissection, to be corroded or perforated.

Arsenic is a poison the most certainly fatal and most difficult to be cured of any, (if we except, perhaps, large doses of antimonial emetics,) on account of its being difficultly soluble in water, and incapable of decomposition. Corrosive sublimate mercury, solution of mercury in aqua fortis, &c. will as certainly poison as arsenic itself: but they are by no means so dangerous; because, being compounded of quicksilver united with an acid, any alkaline substance will infallibly decompose

* The French grain is here meant, which is less than the English, 72 French grains being only equal to 60 English.

compound and destroy the poison, so that scarcely any bad effects can happen but what arise from its first action on the stomach. Arsenic, on the contrary, cannot be decomposed, nor united with any known substance, without a considerable degree of heat. It therefore remains in the stomach, continually exerting its mischievous qualities, till it is all discharged by vomiting.

Many antidotes have been proposed against this pernicious mineral; but, that they might be rationally put confidence in, it should first be demonstrated, that they can make a change upon arsenic in substance, or in solution, in a heat no greater than that of the human body. Alkalies, which have been directed, cannot unite with arsenic when in the stomach. Acids, which have been ordered on a contrary supposition, will indeed dissolve arsenic; but the solution, in all probability, would prove a more violent poison than the arsenic itself. Oils, fats, warm fat broths, fresh butter, or milk, are recommended as the most proper means of obviating the poison, and promoting its discharge by vomit: and indeed in such deplorable cases they are the only remedies to which we can apply; though it is evident the efficacy even of these must be exceedingly uncertain; and for this plain reason, that the arsenic is already in contact with the stomach; and though they might prevent the action of the poison if they had been *first* swallowed, their operation must be exceedingly less efficacious after the poison has had access to the stomach, and begun to exert its virulent effects upon it.

The best method of giving arsenic the metalline form, or changing it into a *regulus*, as it is called, is by mixing it, when powdered, with oil-olive, so as to form a paste; the mixture is to be put into a retort, or glass matras, and to be distilled, or sublimed, with a fire at first very moderate, and sufficient to raise only the oil. After the oil has penetrated the arsenic, its more fluid parts exhale, and it remains in form of a charred coal. Then the fire is to be increased, and the metallized arsenic soon sublimes to the top. When no more sublimes, the vessel is to be broke, and the adhering crust of regulus of arsenic separated. The regulus must be sublimed a second, or even a third time, in order to give it as perfect a metallic form as it can receive. The oil, which arises during this operation, is more fetid than any empyreumatic oil, and almost intolerable.

Regulus of Cobalt and Nickel. See METALLURGY.

SECT. IV. Inflammable Substances.

THESE may be divided into the following classes: 1. Sulphurs. 2. Ardent spirits. 3. Oils and fats. 4. Resins. 5. Bitumens; and, 6. Charcoal.

1. SULPHURS.

1. *Common sulphur*. For the extraction of this substance from its ores, see SULPHUR. The artificial composition of it we have already related, n° 165; and have now only to take notice of a very few of its properties, which come more properly under this section.

Sulphur, as commonly used in commerce and the arts, is of a pale yellow colour, of a disagreeable and

peculiar smell, which is rendered more sensible when it is heated or rubbed. By rubbing, it receives very curious electrical qualities: (See ELECTRICITY.) Its specific gravity is considerably greater than that of water, though less than earths or stones. In close vessels, sulphur is incapable of receiving any alteration. It melts with a very gentle heat; and then is sublimed, adhering to the capital in small, very fine, needle-like crystals, called *flowers of sulphur*. It may thus be sublimed many times without alteration. If sulphur is exposed to a heat barely sufficient to melt it, and, very slowly cooled, it crystallizes in form of many needles crossing one another. Some of these pointed crystals may also be observed in the interior parts of the lumps of sulphur which have been melted, and cast into cylindrical moulds, as they are commonly sold; because the center of these cylindrical rolls is more slowly cooled than the surface. Sulphur also gives this needle-like form to cinnabar, antimony, and many other minerals containing it. Sulphur may be decomposed in several ways. The most simple is by burning; which we have already taken notice of, n° 118. It may also be very effectually decomposed by mixing it with iron filings and water. In this case the phlogiston is dissipated, and the acid uniting with the iron forms a green vitriol.

It is very remarkable, that though sulphur is composed of vitriolic acid and phlogiston, yet the addition of more inflammable matter, so far from making the union stronger, weakens it to a great degree: and hence we have another method of decomposing this substance; namely, by combining it with a large quantity of oil, and distilling the compound.

Sulphur is capable of being easily dissolved in expressed oils, but very difficultly in essential ones. These compositions are called *balsams of sulphur*; and are sometimes employed in medicine, but are found to be of a very heating nature. They are much used by farriers. According to Mr Beaumé, sulphur cannot be dissolved in oil, without a heat sufficient to melt it. A larger quantity is kept dissolved when the mixture is hot, than when cold; and consequently, the sulphur, especially if it has been dissolved in a thin essential oil, crystallizes on cooling the mixture. The sulphur, thus separated from the oil, is found not to be altered in any respect from what it formerly was; but if the mixture is exposed to a degree of heat capable of entirely decomposing the oil, the sulphur is decomposed along with it, and the same products are obtained by distilling this mixture to dryness, as if a mixture of pure oil of vitriol and oil were distilled. These products are, first a portion of oil, when an essential oil was made use of in the composition of the balsam; then some volatile sulphureous acid, which is at first watery, and afterwards becomes stronger; along with this acid more oil arises, which becomes more and more thick towards the end of the distillation; and lastly, when the retort has been made red hot, nothing remains but a fixed coal.

In this process we find, that both the sulphur and oil are decomposed. The acid of the sulphur seems to attack the watery principle of the oil, while its phlogiston remains confounded with that of the oil, or is dissipated in vapours.—Hence, though the vitriolic acid in sulphur

PRACTICE

phur is concentrated to the utmost degree, and perfectly free from water, what rises in this distillation is very aqueous, by reason of the water which it attracts from the oil.

472
How soluble in spirit of wine.

Spirit of wine does not sensibly act upon sulphur in its liquid state; but if both the spirit of wine and sulphur meet in the state of vapour, they will then unite, and a perfect solution will take place. By methods of this kind, many combinations might be effected, which have been hitherto thought impossible.

473
Its union with metals.

Pure sulphur unites easily with all metals; gold, platinum, and zinc, excepted. The compounds, except that with mercury, possess a metallic lustre without any ductility. The sulphur may be separated by exposing the mixture to a strong fire, (see METALLURGY,) or by dissolving the metalline part in acids. The sulphur, however, defends several of the metals from the action of acids; so that this dissolution succeeds but imperfectly. The reguline part of antimony is more easily separated from sulphur by means of acids, than any other metalline substance. Alkaline salts will separate the sulphur from all metals in fusion, but they unite with it themselves, and form a compound equally capable of dissolving the metal. (See ALKALINE SALTS.)

474
Vermilion.

Sulphur united with quicksilver, forms the beautiful pigment called *cinnabar*, or *vermilion*; which is so much used in painting, that the making of it is become a distinct trade. Neuman relates, that in the making of cinnabar by the Dutch method, six or eight parts of quicksilver are made use of to one of sulphur. The sulphur is first melted; and then the quicksilver is stirred into it; upon which they unite into a black mass. In this part of the process the mixture is very apt to take fire; of which it gives notice by swelling up to a great degree. The vessel must then be immediately covered. The mass being beaten to powder, is afterwards to be sublimed in large earthen jars almost of an equal wideness from end to end; these are hung in a furnace by a strong rim of iron. When the matter is put in, the mouth of the vessel is covered, the fire increased by degrees, and continued for several hours, till all the cinnabar has sublimed; care being taken to introduce at times an iron-rod to keep the middle clear; otherwise the cinnabar concreting there, and stopping up the passage, would infallibly burst the vessels.

The quantity of sulphur directed in the common receipts for making cinnabar is greatly larger than the above; being no less than one-third of the quantity of quicksilver employed: accordingly it has been found, that the sublimate, with such a large quantity of sulphur, turned out of a blackish colour, and required to be several times sublimed before it became perfectly red; but we cannot help thinking, that by one gentle sublimation the superfluous sulphur might be separated, and the cinnabar become perfectly pure the second time. Hoffman gives a curious method of making cinnabar without sublimation; by shaking, or digesting a little mercury with volatile tincture of sulphur: the mercury readily imbibes the sulphur from the volatile spirit, and forms with it a deep red powder, not inferior in colour to the cinnabar prepared in the common manner. Dr Lewis has found the common solu-

tions of sulphur by alkalies, or quicklime, to have a similar effect. This cinnabar will likewise be of a darker or lighter colour, according as the solution contains more or less sulphur.

Sulphur is a principal ingredient in gun-powder, (see GUN-POWDER.) It also enters the composition of the *pulvis fulminans*. This consists of three parts of nitre, two of the dry alkali of tartar, and one part of sulphur, well ground together. If a little quantity of this powder is laid on an iron-spoon, or shovel, and slowly heated, it will explode, when it arrives at a certain degree of heat, with astonishing violence and noise. The most probable opinion concerning this is, that the fixed air contained in the alkali is, by the acid vapours acting upon and endeavouring to expel it all at once, driven off with such force, that a loud explosion is produced.

475
Pulvis fulminans.

2. *Phosphorus of Urine*. This is a very inflammable substance, composed of phlogiston united with a certain acid, the properties of which we have already taken notice of, n° 307—310. The preparation of it was long a secret, and only perfectly discovered by Mr Margraaf, who published it in the Berlin Memoirs in 1743. This process being by far the best, and most practicable, we shall content ourselves with inserting it alone.

476
Phosphorus of urine.

Two pounds of sal ammoniac are to be accurately mixed with four pounds of minium, and the mixture distilled in a glass-retort; by which means a very penetrating, caustic alkaline spirit will be obtained. The residuum, after the distillation, is a kind of *plumbum corneum*; n° 149. This is to be mixed with nine or ten pounds of extract of urine, evaporated to the consistence of honey. (Seventy or eighty gallons of urine are required to produce this quantity of extract.) The mixture is to be made slowly in an iron pot set over the fire, and the matter frequently stirred. Half a pound of powdered charcoal is then to be added, and the evaporation continued till the whole is reduced to a black powder. This powder is to be put into a retort; and urged with a graduated heat, till it becomes red hot, in order to expel all the volatile alkali, fetid oil, and ammoniacal salt, that may be contained in the mixture. After the distillation, a black friable residuum remains, from which the phosphorus is to be extracted by a second distillation, and a stronger heat. Before it is subjected to another distillation, it may be tried by throwing some of it upon hot coals. If the matter has been well prepared, a smell of garlic exhales from it, and a blue phosphorical flame is seen undulating along the surface of the coals.

477
Mr Margraaf's process for making.

The matter is to be put into a good earthen retort, capable of sustaining a violent fire. Three quarters of the retort are to be filled with the matter which is to yield the phosphorus, and it is to be placed in a furnace capable of giving a strong heat. Mr Margraaf divides the matter among six retorts, so that if any accident happens to one, the whole matter is not lost. The retorts ought to be well luted to a receiver of a moderate size, pierced with a small hole, and half full of water; and a small wall of bricks must be raised between the furnace and receiver, in order to guard this vessel against heat, as much as possible. The retorts are to be heated by slow degrees for an hour and an half; then the heat is to be increased till the vessels

are

PRACTICE are red hot, when the phosphorus ascends in luminous vapours. When the retort is heated till between a red and white, the phosphorus passes in drops, which fall and congeal in the water at the bottom of the receiver. This degree of heat is to be continued till no more comes over. When a retort contains eight pints or more, this operation continues about five hours.

478
Rectification
of phosphorus.

In the first distillation, phosphorus never passes pure, but is always of a blackish colour, by reason of its carrying along with it some part of the coal. From this, however, it may be purified, by rectification in a small glass-retort, to which is luted a receiver half full of water. A very gentle heat is sufficient; because phosphorus, once formed, is very volatile; and as the fuliginous matter was raised probably by the fixed air emitted by the charcoal, in the instant of its union with the phosphoric acid, none of it can arise in a second distillation.

The phosphorus is then to be divided into small cylindrical rolls, which is done by putting it in glass-tubes immersed in warm water; for the phosphorus is almost as fusible as fuel. It takes the form of the glass-tubes; from which it may be taken out, when it is cold and hardened. This must be done under water, least the phosphorus should take fire.

479
Process
Sometimes
dangerous.

This concrete continually appears luminous in a dark place; and by a very slight heat takes fire, and burns far more vehemently than any other known substance. Hence, it is necessary to be very cautious in the distillation of it; for if the receiver should happen to break while the phosphorus is distilling, and a little flaming phosphorus fall upon the operator's legs or hands it would burn its way to the bone, in less than three minutes. In this case, according to Mr Hellot, nothing but urine will stop its progress.

Though phosphorus takes fire very readily by itself, it does not inflame at all by grinding it with other inflammable bodies, as camphor, gun-powder, or essential oils. In grinding it with nitre, some luminous flashes are observed; but the mixture never burns, unless the quantity of phosphorus be large in proportion to the nitre: rubbed pretty hard on a piece of paper or linen, it sets them on fire if they are rough, but not if they are smooth. It fires written paper more readily than such as is white, probably from the former having more asperities. On grinding with iron filings, it presently takes fire.

480
Liquid
phosphorus.

Oils ground with phosphorus, appear, like itself, luminous in a temperately warm place; and thus become a liquid phosphorus, which may be rubbed on the hands, &c. without danger. Liquid phosphorus is commonly prepared by grinding a little of the solid phosphorus with oil of cloves, or rubbing it first with camphor, and this mixture with the oil. A luminous *amalgam*, as it is called, may be obtained, by digesting a scruple of solid phosphorus with half an ounce of oil of lavender, and, when the phosphorus begins to dissolve and the liquor to boil, adding a drachm of pure quicksilver; then briskly shaking the glass for five or six minutes, till they unite.

481
Experiments
on phosphorus
with spirit
of wine.

Rectified spirit of wine, digested on phosphorus, extracts a part of it, so as to emit luminous flashes on being dropt into water. It is computed that one part

of phosphorus will communicate this property to 600,000 parts of spirit. The liquor is never observed to become luminous of itself, nor in any other circumstance except that above mentioned. By digestion for some months, the undissolved phosphorus is reduced to a transparent oil, which neither emits light, nor concretes in the cold. By washing with water, it is in some measure revived; acquiring a thicker consistence, and becoming again luminous, though in a less degree than at first. During this digestion, the glass is very apt to burst.

Phosphorus is partially dissolved by expressed oils; and totally, or almost so, in essential oils, and ether. When essential oils are saturated with it by heat, a part of the phosphorus separates, on standing in the cold, in a crystalline form. Concentrated spirit of salt has no action on it. In distillation, the spirit rises first, and the phosphorus after it unchanged. Spirit of nitre dissolves it, and the dissolution is attended with great heat and copious red fumes, so that great part of the spirit distils without the application of any external heat, and the phosphorus at last takes fire, explodes, and bursts the vessels. Oil of vitriol, likewise, dissolves phosphorus, but not without a heat sufficient to make the acid distil. The distilled liquor is white, thick, and turbid; the residuum is a whitish tenacious mass, which deliquesces, but not totally, in the air. Phosphorus itself is resolved into an acid liquor on being exposed two or three weeks to the air, its inflammable principle seeming by degrees to be dissipated.

Phosphorus has been reported to produce extraordinary effects in the resolution of metallic bodies: but from the experiments that have been made with this view, it does not appear to have any remarkable action on them; at least on the precious ones, gold and silver, for the resolution or subtilization of which it has been chiefly recommended. The following experiments were made by Mr Margraaf.

1. A scruple of filings of gold were digested with a drachm of phosphorus for a month, and then committed to distillation. Part of the phosphorus arose, and part remained above the gold, in appearance resembling glass: this grew moist on the admission of air, and dissolved in water, leaving the gold unaltered. Half a drachm of fine silver, precipitated by copper, being digested with a drachm of phosphorus for three hours, and the fire then increased to distillation, the greatest part of the phosphorus arose pure, and the silver remained unchanged. Copper filings being treated in the same manner, and with the same quantity of phosphorus, the phosphorus sublimed as before; but the remaining copper was found to have lost its metallic brightness, and to take fire on the contact of flame. Iron filings suffered no change. Tin filings run into granules, which appeared to be perfect tin. Filings of lead did the same. The red calx of mercury, called *precipitate per se*, treated in the same manner, was totally converted into running quicksilver. 2. Regulus of antimony suffered no change itself, but occasioned a change in the consistence of the phosphorus, which, after being distilled from this semi-metal, refused to congeal, and continued under water, fluid like oil-olive. With bismuth there was no alteration. A drachm of

482
With essen-
tial oils and
acids.

483
Mr Margraaf's ex-
periments
with metals.

PRACTICE phosphorous being distilled and cohobated with an equal quantity of zinc, greatest part of the zinc sublimed in form of very light pointed flowers, of a reddish-yellow colour : these flowers, injected into a red hot crucible, took fire, and run into a glass resembling that of borax. White arsenic, sublimed with phosphorus, arose along with it in form of a mixed red sublimate. Sulphur readily unites with phosphorus, into a mass which smells like *hepar sulphuris*. This does not easily take fire on being rubbed ; but, exposed to a moderate dry heat, it flames violently, and emits a strong sulphureous fume. If phosphorus is burnt in an open vessel, a quantity of acid remains behind ; and if a glass bell is held over it, an acid likewise sublimes in the form of white flowers.

484
Mr Canton's phosphorus.

3. *Mr Canton's phosphorus*. This is a composition of quicklime and common sulphur. The receipt for making it is as follows. " Calcine some common oyster-shells, by keeping them in a good coal-fire for half an hour ; let the purest part of the calx be pulverized and sifted. Mix with three parts of this powder, one part of flowers of sulphur. Let this mixture be rammed into a crucible of about an inch and a half in depth, till it be almost full ; and let it be placed in the middle of the fire, where it must be kept red hot for one hour at least, and then set by to cool : when cold, turn it out of the crucible ; and cutting or breaking it to pieces, scrape off, upon trial, the brightest parts ; which, if good phosphorus, will be a white powder." This kind of phosphorus shines on being exposed to the light of the sun, or on receiving an electrical stroke.

4. *Phosphorus of Homberg*. This substance, which has the singular property of kindling spontaneously when exposed to the air, was accidentally discovered by Mr Homberg, as he was endeavouring to distil a clear flavourless oil from human excrements. Having mixed the excrement with alum, and distilled over as much as he could with a red heat, he was much surprised at seeing the matters left in the retort take fire upon being exposed to the air, some days after the distillation was over. This induced him to repeat the operation, in which he met with the same success ; and he then published a process wherein he recommended alum and human excrement for the preparation of the phosphorus. Since his time, however, the process has been much improved ; and it is discovered, that almost every vitriolic salt may be substituted for the alum, and most other inflammable substances for the excrement ; but though alum is not absolutely necessary for the success, it is one of the vitriolic salts that succeed best. The following process is recommended in the Chemical Dictionary.

485
Best method of preparing.

Let three parts of alum and one of sugar be mixed together. This mixture must be dried in an iron shovel, over a moderate fire, till it be almost reduced to a blackish powder or coal ; during which time it must be stirred with an iron spatula. Any large masses must be bruised into powder ; and then it must be put into a glass matrafs, the mouth of which is rather strait than wide, and seven or eight inches long. This matrafs is to be placed in a crucible, or other earthen vessel, large enough to contain the belly of the matrafs, with about a space equal to that of a finger all round it. This space is to be filled with sand, so that

the matrafs shall not touch the earthen vessel. The apparatus is then to be put into a furnace, and the whole to be made red hot. The fire must be applied gradually, that any oily or fuliginous matter may be expelled ; after which, when the matrafs is made red hot, sulphureous vapours exhale : this degree of heat is to be continued, till a truly sulphureous flame, which appears at the end of the operation, has been seen nearly a quarter of an hour : the fire is then to be extinguished, and the matrafs left to cool, without taking it out of the crucible ; when it ceases to be red hot, it must be stopped with a cork. Before the matrafs is perfectly cold, it must be taken out of the crucible, and the powder it contains poured as quickly as possible into a very dry glass vial, with a glass stopper. If we would preserve this phosphorus a long time, the bottle containing it must be opened as seldom as possible. Sometimes it kindles while it is pouring into the glass vial ; but it may be then extinguished by closing the vial expeditiously. A small quantity of this phosphorus laid on paper, and exposed to the air, immediately takes fire, becomes red like burning coals, and emits a strong sulphureous vapour greatly resembling that which arises on decomposing liver of sulphur.

486
Theory.

The most plausible theory of this strange appearance is, that, during the operation, part of the vitriolic acid combines with the phlogiston of the coal, into perfect sulphur ; while part remains imperfectly combined either with the phlogiston, or the earthy basis of the alum. This last part, which is also exceedingly concentrated, probably attracts the moisture of the air so strongly, as to produce the heat requisite for kindling the coal-y matter.

II. ARDENT SPIRITS.

See FERMENTATION AND DISTILLATION.

III. OILS.

1. *Essential Oils*. Those oils are called *essential* which have evidently the smell of the vegetable from which they are drawn. For the method of procuring them, see DISTILLATION. They are distinguished from all others by their superior volatility, which is so great as to cause them rise with the heat of boiling water. All these have a strong aromatic smell, and an acid, caustic taste ; in which respect also they differ from other oils. This taste is thought to proceed from a copious and disengaged acid, with which they are all penetrated. The presence of this disengaged acid in essential oils, appears from the impression they make upon the corks of bottles in which they are kept. These corks are always stained of a yellow colour, and a little corroded, nearly as they are by nitrous acid. The vapour of these oils also reddens blue paper, and converts alkalis into neutral salts.

487
Essential oils.

488
Supposed cause of their taste.

This acid is likewise supposed to be the cause of their solubility in spirit of wine. They are not all equally soluble in this menstruum, because they do not all contain an equal quantity of acid. As this acid is much disengaged, they lose a great deal of it by repeated distillations, and therefore they become less and less soluble on being frequently distilled. By evaporation they lose their most volatile and thin part, in which the specific smell of the vegetable from which

489
Of their solubility in spirit of wine.

which they are extracted refides; by which lofs they become thick, and acquire the fmell and confidence of turpentine, and even of refin. In this ftate they are no longer volatile with the heat of boiling water; and, if diftilled with a ftrouger fire, they give over an oil which has neither fmell nor tafte of the vegetable whence they were extracted, but is entirely empyreumatic, and fimilar to thofe oils procured by diftilling vegetable or animal fubftances with a ftong fire. See DISTILLATION.

To the clafs of effential oils, the volatile concrete called camphor feems moft properly to belong. With them it agrees in its properties of inflammability, folubility in fpirit of wine, and a ftong aromatic flavour. The only differences between them are, that camphor is always in a folid ftate, and is incapable of decomposition by any number of fublimations.

According to Neuman, all the camphor made ufe of is the produce of two fpecies of trees; the one growing in Sumatra and Borneo, the other in Japan. Of thefe, the Japan kind is the only one brought into Europe. The tree is about the fize of a large lime, the flowers white, and the fruit a fmall red berry. All parts of the tree are impregnated with camphor; but the roots contain moft, and therefore are chiefly made ufe of for the preparation of this commodity; though, in want of them, the wood and leaves are fometimes mixed.

The camphor is extracted by diftillation with water in large iron pots filled with earthen heads ftuffed with ftraw; greateft part of the camphor concretes among the ftraw, but part paffes down into the receiver among the water. In this ftate it is found in fmall bits like gray falt-petre, or common bay-falt; and requires to be purified either by a fecond fublimation, or by diffolution in fpirit of wine, filtration, and exficcation. If the firft method is followed, there will be fome difficulty in giving it the form of a perfect transparent cake. A difficulty of this kind indeed always occurs in fublimations, and the only way is to keep the upper part of the glafs of fuch a degree of heat as may keep the fubimate in a half-melted ftate. Dr Lewis recommends the depuration of camphor by fpirit of wine, and then melting it into a cake in the bottom of a glafs.

Camphor poffeffes confiderable antifeptic virtues; and is a good diaphoretic without heating the conftitution, with which intention it is often ufed in medicine. It is likewife employed in fire-works and feveral other arts, particularly in making varnifhes. See VARNISH.

This fubftance diffolves eafily and plentifully in vinous fpirits and in oils; four ounces of fpirit of wine will diffolve three of camphor. On diftilling the mixture, the fpirit rifes firft, very little camphor coming over with it. This fhows that camphor, however volatile it may feem by its fmell, is very far from having the volatility of ether, and confequently is improperly claffed with fubftances of that kind. It is diffolved, but not altered in the leaft, by the ftroongeft mineral acids; always feparating from them in its proper form, on the affufion of water. It may however be changed into a fluid oil by repeated diftillations from bole or other loamy earths.

2. *Empyreumatic Oils.* Under this name are comprehended all thofe oils, from whatever fubftance obtained, which require a greater heat for their diftillation than that of boiling water. Thefe are partially foluble in fpirit of wine, and become more and more fo by repeated diftillations. The empyreumatic oils obtained from animal fubftances are at firft more feid than thofe procured from vegetables; but by repeated diftillations, they become exceedingly attenuated and volatile, becoming almoft as white, thin, and volatile, as ether. They then acquire a property of ading upon the brain and nervous fyftem, and of allaying its irregular movements, which is common to them with all other inflammable matters when highly attenuated and very volatile; but this kind of oil is particularly recommended in epileptic and convulfive affections. It is given from four to 10 or 12 drops: but, though prepared with the utmoft care, it is very fufceptible of lofing its whitenefs, and even its thinnefs, by a fhort expofure to air; which proceeds from the almoft infantaneous evaporation of its more thin and volatile parts, and from the property which the left volatile remainder has of acquiring colour. To avoid this inconvenience, it muft be put, as foon as it is made, into very clean glafs bottles with glafs ftoppers, and expofed to the air as little as poffible.

The moft important obfervations concerning the method of making the pure animal oil are, firft to change the veffels at each diftillation, or at leaft to make them perfectly clean; for a very fmall quantity of the thicker and left volatile part is fufficient to fpoil a large quantity of that which is more rectified. In the fecond place, Mr Beaume has obferved, that this operation may be greatly abridged, by taking care to receive none but the moft volatile part in each diftillation, and to leave a large refiduum, which is to be neglected, and only the more volatile part to be further rectified. By this method a confiderable quantity of fine oil may be obtained at three or four diftillations, which could not otherwife be obtained at fifty or fixty.

3. *Animal Fats.* Though thefe differ confiderably from one another in their external appearance, and probably in their medicinal qualities, they afford, on a chemical analyfis, products fimilar in quality, and differing but inconfiderably in quantity. They all yield a large proportion of oil, and no volatile falt; in which refpect they differ from all other animal fubftances. Two ounces of hog's lard yielded, according to Neuman, two drachms of an empyreumatic liquor, and one ounce five drachms and 50 grains of a clear brown-coloured oil of a volatile fmell, fomewhat like horfe-radifh. The *caput mortuum* was of a fhining black colour, and weighed 10 grains.

Tallow being diftilled in the fame manner, two drachms of empyreumatic liquor were obtained from two ounces of it; of a clear brown oil, fmelling like horfe-radifh, one ounce fix drachms and 12 grains. The remaining coal was of a fhining black colour, and weighed 18 grains.

The marrow of bones differs a little from fats, when chemically examined. Four ounces of frefh marrow, diftilled in the ufual manner, gave over three drachms and a fcruple of a liquor which fmelled like tal-
low;

PRACTICE

low; two scruples and an half of a liquor which had more of an empyreumatic and a foetid smell; two ounces and an half of a yellowish-brown, butyraceous oil, which smelled like horle-radish; and six drachms and an half of a blackish-brown oil of the same smell. The *caput mortuum* weighed four scruples.

497
Rancid oils
purified.

All animal fats, when perfectly pure, burn totally away without leaving any feces, and have no particular smell. In the state in which we commonly find them, however, they are exceedingly apt to turn rancid, and emit a most disagreeable and noxious smell; and to this they are peculiarly liable, when long kept in a gentle degree of heat. In this state, too, an inflammable vapour arises from them, which when on fire is capable of producing explosions. Hence, in those works where large bellows are used, they have been often suddenly burst by the inflammable vapours arising from the rancid oil employed for softening the leather. The expressed unctuous oils of vegetables are subject to the same changes: but from this rancidity they may all be freed most effectually, by the simple process of agitating them well with water; which is to be drawn off, and fresh quantities added, till it comes off, at last, clear and insipid, without any ill smell. The proper instrument for performing this operation in large, is a barrel-churn, having in it four rows of narrow split deals, from the center to the circumference, each piece set at obtuse angles to the other, in order to give different directions to the oil and water as the churn turns round, thereby to mix them more intimately. The churn is to be swiftly turned round for a few minutes; and must then be left at rest, till the oil and water have fully separated; which will be in 15 or 20 minutes, more or less, according to the size of the churn. When this water is drawn off, fresh water is to be put in, and the churn again turned round, and this continued till the oil is perfectly sweet. If the oil and water are allowed to stand together for some days, a gelatinous substance is found between them, which is not very easily miscible either with oil or water. Chalk, quicklime, and alkaline salts, are found also capable of taking off the rancidity from oils and fats; but have the inconvenience of destroying a part of their substance.

IV. RESINS and BALSAMS.

These are commonly reckoned to be composed of an essential oil thickened by an acid; as the essential oils themselves are found to be convertible into a simillar substance, by the exhalation of their more volatile parts. True resins are generally transparent in a considerable degree; soluble in spirit of wine; and possessed of a considerable degree of flavour.

498
Whence
procured.

Resins are originally produced by inspissating the natural juices which flow from incisions made in the stems of growing vegetables, and are in that state called *balsams*. The balsams may be considered as essential oils thickened by losing some of their odoriferous principle, and of their finest and most volatile part. There are several kinds of balsams; which, however, differ from each other only in the smell, and degree of consistence; and, therefore, all yield simillar products on distillation. An analysis of turpentine therefore will be sufficient as an example

of the analysis and natural properties of all the rest.

The true turpentine-tree is found in Spain and the southern parts of France, as well as in the island of Chio and in the Indies. It is a middling sized evergreen tree, with leaves like those of the bay, bearing purplish, imperfect flowers; and, on separate pedicles, hard, unctuous berries, like those of juniper. It is extremely resinous; and, unless the resin is discharged, decays, produces fungous excrescences, swells, bursts, and dies; the prevention of which consists wholly in plentiful bleeding, both in the trunk and branches. The juice is the *Chio* or *Cyprus turpentine* of the shops. This sort is quite of a thick consistence, of a greenish white colour, clear and transparent, and of scarcely any taste or smell.

The kind now called *Venice turpentine*, is no other than a mixture of eight parts of common yellow or black rosin with five parts of oil of turpentine. What was originally Venice turpentine is now unknown. Neuman relates, that the Venice turpentine sold in his country was no other than that prepared from the larix tree, which grows plentifully in some parts of France, as also in Austria, Tyrol, Italy, Spain, &c. Of this there are two kinds; the young trees yielding a thin limpid juice, resembling balm of copaiba; the older, a yellower and thicker one.

The *Straßburgh turpentine* is extracted from the silver-fir. Dr Lewis takes notice that some of the exotic firs afford balsams, or resins, superior to those obtained from the native European ones; as particularly that called *balm of Gilead fir*, which is now naturalized to our own climate. A large quantity of an elegant resinous juice may be collected from the cones of this tree: the leaves also, when rubbed, emit a fragrant smell; and yield, with rectified spirit, an agreeable resinous extract.

The common turpentine is prepared from different sorts of the pine; and is quite thick, white, and opaque. Even this is often counterfeited by mixtures of rosin and common expressed oils.

All the turpentines yield a considerable proportion of essential oil. From sixteen ounces of Venice turpentine, Neuman obtained, by distillation with water, four ounces, and three drachms of oil. The same quantity distilled, without addition, in the heat of a water bath, gave but two ounces and an half; and from the residuum treated with water, only an ounce could be obtained. The water remaining in the still is found to have imbibed nothing from the turpentine: on the contrary, the turpentine is found to imbibe part of the water; the residuum and the oil amounting to a full ounce on the pound more than the turpentine employed. When turpentine is distilled, or boiled with water till it becomes solid, it appears yellowish; when the process is further continued, of a reddish brown colour: in the first state, it is called *boiled turpentine*; and in the latter, *colophony*, or *resin*.

On distilling sixteen ounces of turpentine in a retort with an open fire, increased by degrees, we obtain first four ounces of a limpid colourless oil; then two ounces and two drachms of a yellowish one; four ounces and three drachms of a thicker yellow oil; and two ounces and one drachm of a dark brownish

504
Essential
oil difficult
of solution. The limpid essential oil called *spirit of turpentine*, is exceedingly difficult of solution in spirit of wine; though turpentine itself dissolves with great ease. One part of the oil may indeed be dissolved in seven parts of rectified spirit; but, on standing for some time, the greatest part of the oil subsides to the bottom, a much greater proportion of spirit being requisite to keep it dissolved.

505
Benzoïn. 2. *Benzoïn*: This is a very brittle brownish resin, of an exceedingly fragrant smell. The tree which produces benzoïn is a native of the East Indies; particularly of Siam, and the island of Sumatra. It is never permitted to exceed the sixth year; being, after this time, unfit for producing the benzoïn. It is then cut down, and its place supplied by a young tree raised commonly from the fruit. One tree does not yield above three pounds of benzoïn.

A tree supposed to be the same with that which affords benzoïn in the East Indies, is plentiful also in Virginia and Carolina; from whence it has been brought into England, where it grows with vigour in the open ground. The bark and the leaves have the smell of benzoïn; and yield with rectified spirit a resin of the same smell: but no resin has been observed to issue from it naturally in this climate; nor has any benzoïn been collected from it in America.

506
Soluble in
spirit of
wine. Benzoïn dissolves totally in spirit of wine into a blood-red liquor, leaving only the impurities, which commonly amount to no more than a scruple on an ounce. To water, it gives out a portion of saline matter of a peculiar kind, volatile and sublimable in the fire; and which is most effectually freed by sublimation.

507
Flowers of
benzoïn. This substance, called *flowers of benzoïn*, is best prepared by moistening benzoïn, grossly powdered, with spirit of wine; and then proceeding to distillation with a very gentle heat, in a wide-necked glass-retort. The flowers arise immediately after the spirit, partly in a concrete saline form, and partly in that of a white butter. The receiver being now changed, and the fire increased, a small portion of brown-coloured flowers sublimes; followed, first, by a subtile oil; afterwards by a brownish oil; and last of all by a black, thick, empyreumatic one, together with an acid spirit. If the flowers and butter be dissolved in distilled water, over a gentle fire, the solution filtered, and set in the cold, the saline matter shoots into crystalline concretions of a fine silver whiteness; this salt, like tartar, being difficult of solution; and, when dissolved in hot water, separating again as the liquor cools. The dissolution and filtration should be performed as expeditiously, and the vessel kept as much covered, as possible, to prevent any considerable dissipation of the volatile matter. The salt still retains, even after this purification, a portion of oil; as appears from its penetrating smell, and from its burning in the fire. The spirit of wine, which arises at first in the distillation, is impregnated with a little of the salt. The oil which follows the flowers, re-distilled from earthy powders, or with water, may be used as an essential oil of benzoïn; for it has little or nothing of an empyreumatic taint. From 16 ounces of benzoïn are obtained two

PRACTICE ounces of rough flowers, nine ounces of oil, and seven scruples of an acid spirit. The residuum weighs two ounces and an half.

The principal use of resins is in the making of lacquers, varnishes, &c. See VARNISH.

V. BITUMENS.

These are inflammable mineral bodies, not sulphureous, or only casually impregnated with sulphur. They are of various degrees of consistency; and seem, in the mineral kingdom, to correspond with the oils and resins in the vegetable.

Concerning the origin of bitumens, chemists are not at all agreed. Some chemical writers, particularly Mr Macquer, imagine bitumens to be no other than vegetable resins altered in a particular manner by the admixture of some of the mineral acids in the earth; but Dr Lewis is of a contrary opinion, for the following reasons.

“Mineral bitumens are very different in their qualities from vegetable resins; and, in the mineral kingdom, we find a fluid oil very different from vegetable oils. The mineral oil is changed by mineral acids into a substance greatly resembling bitumens; and the vegetable oils are changed by the same acids into substances greatly resembling the natural resins.” (Here we cannot help differing from the Doctor, as we have never seen or heard of any instance of such a change taking place, on mixing a mineral acid with any vegetable oil, either expressed or distilled.) “From bitumens we obtain, by distillation, the mineral oil, and from resins the vegetable oil, distinct in their qualities as at first. Vegetable oils and resins have been treated with all the known mineral acids; but have never yielded any thing similar to the mineral bitumens. It seems, therefore, as if the oily products of the two kingdoms were essentially and specifically different. The laws of chemical inquiries at least demand, that we do not look upon them any otherwise, till we are able to produce from one a substance similar to the other. When this shall be done, and not before, the presumption that nature effects the same change in the bowels of the earth, will be of some weight.”

There is a perfectly fluid, thin bitumen, or mineral oil, called *naphtha*, clear and colourless as crystal; of a strong smell; extremely subtile; so light as to swim on all known liquors, ether perhaps excepted; spreading to a vast surface on water, and exhibiting rainbow-colours; highly inflammable: formerly made use of in the composition of the supposed inextinguishable greek fire.

Next to this in consistence is the *oleum petra*, or *petroleum*; which is grosser and thicker than naphtha, of a yellowish, reddish, or brownish colour; but very light, so as to swim even on spirit of wine. By distillation, the petroleum becomes thinner and more subtile, a gross matter being left behind; it does not, however, easily arise, nor does it totally lose its colour by this process, without particular managements or additions.

Both naphtha and petroleum are found plentifully in some parts of Persia, trickling through rocks, or swimming on the surface of waters. Kemper gives an account of two springs near Baku; one affording naphtha,

508
Origin of
bitumens.

509

510
Petroleum.

PRACTICE naphtha, which it receives in drops from subterraneous veins; the other, a blackish and more terid petroleum, which comes from Mount Caucasus. The naphtha is collected for making varnishes; the petroleum is collected in pits, and sent to different places for lamps and torches.

Native petrolea are likewise found in many different places, but are not to be had in the shops; what is sold there for petroleum, being generally oil of turpentine coloured with alkanet root. The true naphtha is recommended against disorders of the nerves, pains, cramps, and contractions of the limbs, &c.; but genuine naphtha is rarely or never brought to this country.

There are some bitumens, such as amber, ambergrease, pit-coal, and jet, perfectly solid; others, such as Barbadoes tar, of a middle consistence between fluid and solid. Turf and peat are likewise thought to belong to this class.

511
Amber.

1. *Amber*. This substance melts, and burns in the fire, emitting a strong peculiar smell. Distilled in a strong heat, it yields a phlegm; an oil; and a particular species of acid salt, (n° 313, — 315). The distillation is performed in earthen or glass-retorts, frequently with the addition of sand, sea-salt, coals, &c. which may break the tenacity of the melted mass, so as to keep it from swelling up, which it is apt to do by itself. These additions, however, make a perceptible difference in the produce of the distillation: with some, the salt proves yellowish and dry; with others, brownish or blackish, and unctuous or soft like an extract: with some, the oil is throughout of a dark-brown colour; with others, it proves externally green, or greenish; with elixated ashes, in particular, it is of a fine green. The quantity of oil and phlegm is greatest when coals are used, and that of salt when sea-salt is used.

512
Mostadvan-
taneously
distilled
without ad-
dition.

The most advantageous method of distilling amber, however, is without any addition; and this is the method used in Prussia, where the greatest quantities of salt and oil of amber are made. At first a phlegmatic liquor distils; then a fluid oil; afterwards one that is thicker and more ponderous; and last of all, an oil still more ponderous along with the salt. In order to collect the salt more perfectly, the receiver is frequently changed; and the phlegm, and light oil, which arise at first, are kept by themselves. The salt is purified, by being kept some time on bibulous paper, which absorbs a part of the oil; and changing the paper as long as it receives any oily stain. For the further depuration as well as the nature of this salt, see **SUCCINUM**.

513
Amber-
grease.

2. *Ambergrease*. This concrete, which is only used as a perfume, yields, on distillation, products of a similar nature to that of amber, excepting that the volatile salt is in much less quantity. See **AMBERGREASE**.

514
Pit-coal.

3. *Pit-coal*. [See the articles **COALERIES** and **LITHANTHRAX**]. This substance yields by distillation, according to the translator of the Chemical Dictionary, 1. a phlegm, or water; 2. a very acid liquor; 3. a thin oil, like naphtha; 4. a thicker oil, resembling petroleum, which falls to the bottom of the former, and which rises with a violent fire; 5. an acid, concrete salt; 6. an *uninflammable earth*, (we suppose he means a piece of charred coal, or cin-

der), remains in the retort. The fluid oil obtained from coals is said to be exceedingly inflammable, so as to burn upon the surface of water, like naphtha itself.

4. *Peat*. There are very considerable differences in this substance, proceeding probably from the admixture of different minerals: for the substance of peat is plainly of vegetable origin; whence it is found to answer for the smelting of ores, and the reduction of metallic calces, nearly in the same manner as coals of wood. Some sorts yield, in burning, a very disagreeable smell, which extends to a great distance; whilst others are inoffensive. Some burn into grey or white, and others into red, ferruginous ashes. The ashes yield, on elixation, a small quantity of alkaline, and some neutral salt.

The smoke of peat does not preserve or harden flesh like that of wood; and the foot into which it condenses is more apt to liquefy in moist weather. On distilling peat in close vessels, there arises a clear insipid phlegm; an acid liquor; which is succeeded by an alkaline one, and a dark-coloured oil. The oil has a very pungent taste, and an empyreumatic smell; less fetid than that of animal substances, but more so than that of mineral bitumens. It congeals, in the cold, into a pitchy mass, which liquefies in a small heat: it readily catches fire from a candle; but burns less vehemently than other oils, and immediately goes out upon removing the external flame. It dissolves almost totally in rectified spirit of wine, into a dark, brownish-red, liquor.

515
Peat.

516
Phenomena
on distilla-
tion.

VI. CHARCOAL.

This is the form to which all inflammable matters are reducible, by being subjected to the most vehement action of fire in close vessels; but though all the coals are nearly similar to one another in appearance, there is nevertheless a very considerable difference among them as to their qualities. Thus the charcoal of vegetables parts with its phlogiston very readily, and is easily reducible to white ashes; charred pit-coal, or, as it is commonly called, *coak*, much more difficultly; and the coals of burnt animal-substances, far more difficultly than either of the two. Mr Macquer acquaints us, that the coal of bullock's blood parts with its phlogiston with the utmost difficulty. He kept it very red, in a shallow crucible, surrounded with charcoal, for six hours and more, stirring it constantly that it might be all exposed to the air, without being able to reduce it to white, or even grey ashes. It still remained very black, and full of phlogiston. The coals of pure oils, or concrete oily substances, and foot, which is a kind of coal raised during the inflammation of oils, are as difficultly burnt as animal coals. These coals contain very little saline matter, and their ashes furnish no alkali. These coals, which are so difficultly burnt, are also less capable of inflaming with nitre than others more combustible; and some of them, in a great measure, resist even the action of nitre itself.

Charcoal is the most refractory substance in nature; no instance having been known of its ever being melted, or shewing the least disposition to fusion, either by itself, or with additions: hence, charcoal is found to be the most proper support for such bodies as are to be exposed to the focus of a large burning glass.

517
Differences
between the
coals of dif-
ferent sub-
stances.

518
Charcoal
perfectly
refractory.

The

PRACTICE The only true solvent of charcoal is *hepar sulphuris*. See n° 325.

The different quantities of phlogiston contained in different coals, and perhaps some other circumstances, render some kinds of charcoal much less fit to be used in reviving metals from their cakes, or in smelting them originally from their ores. The coals of vegetable substances are found to answer best for this purpose. See METALLURGY.

SECT. V. Vegetable and Animal Substances.

THE only substances afforded by vegetables or animals, which we have not yet examined, are the mucilaginous, or gummy; and the colouring parts obtained by infusion, or boiling in water. The last of these are treated of under the article *COLOUR-Making*, to which we refer; and in this section shall only consider the nature of mucilage, or gum.

519
Mucilage.

The mucilage of vegetables is a clear transparent substance, which has little or no taste or smell, the consistence of which is thick, ropy, and tenacious, when united with a certain quantity of superabundant water. It is entirely and intimately soluble in water, and contains no disengaged acid or alkali.

When mucilage is dissolved in a large quantity of water, it does not sensibly alter the consistence of the liquor: but, by evaporation, the water grows more and more thick; and, at last, the matter acquires the consistence of gum-arabic, or glue; and this without losing its transparency, provided a heat not exceeding that of boiling water has been used.

520
Phenomena on distillation.

Gums, and solid mucilages, when well dried and very hard, are not liquefied in the fire like resins, but swell, and emit many watery fumes; which are, at first, watery; then oily, fuliginous, and acrid. Distilled in close vessels, an aqueous acid liquor comes over,

along with an empyreumatic oil, as from other vegetable substances; a considerable quantity of coal remains, which burns to ashes with difficulty.

Mucilages and gums are not soluble either by oils, spirit of wine, alkalies, or acids, except in so far as they dissolve in these liquors by means of the water in which the alkali or acid are dissolved. They are, however, the most effectual means of uniting oil with water. Three parts of mucilage, poured upon one part of oil, will incorporate with it by trituration or agitation; and the compound will be soluble in water. Vegetable gums are used in medicine, as well as the mechanic arts: but the particular uses to which each of them is applicable, will be mentioned under the name of each particular gum.

The mucilage obtained from animal substances, when not too thick, is called *jelly*, or *gelatinous matter*; when further inspissated, the matter becomes quite solid in the cold, and is called *glue*. If the evaporation is still further continued, the matter acquires the consistence of horn.

521
Jelly and glue.

This gelatinous substance seems to be the only true animal one; for all parts of the body, by long continued boiling, are reducible to a jelly, the hardest bones not excepted. Animal jelly, as well as vegetable mucilage, is almost insipid and inodorous; but, though it is difficult to describe the difference betwixt them when apart, it is very easily perceived when they are both together. Acids and alkalies, particularly the latter, dissolve animal jellies with great ease; but the nature of these combinations is not yet understood. The other properties of this substance are common to it with the vegetable gums, except only that the animal mucilage forms a much stronger cement than any vegetable gum; and is therefore much employed for mechanical purposes, under the name of *glue*. See *GLUE*, and *ISINGLASS*.

C H E

CHEMNITZ (Martin), a famous Lutheran divine, the disciple of Melancthon, was born at Britzen in Brandenburg, in 1522. He was employed in several important negotiations by the princes of the same communion; and died in 1589. His principal work is, the *Examen of the Council of Trent*, in Latin.

CHEMOSH. See CHAMOS.

CHEMOSIS, a disease of the eyes, proceeding from an inflammation; wherein the white of the eye swells above the black, and overtops it to such a degree, that there appears a sort of gap between them. Others define it to be an elevation of the membrane which surrounds the eye, and is called the white; being an affection of the eye, like white flesh.

CHENOPODIUM, GOOSE-FOOT, or WILD ORACH; a genus of the dignity order, belonging to the pentandria class of plants. There are 18 species, 13 of which are natives of Britain. The most remarkable are the following: 1. The bonus henricus, or common English mercury, found growing naturally in shady lanes in many places in Britain. It has large triangular, arrow-pointed, entire leaves; upright, thick, striated stalks, garnished with triangular leaves, and terminated by close spikes of apetalous yellowish-green flowers

VOL. III.

C H E

in June and July, which are succeeded by ripe seeds in August. 2. The scoparia, belvedere, or annual mock-cypreis. The merit of this consists in its beautiful pyramidal form, resembling a young cypreis tree. 3. The botrys, or oak of Jerusalem. 4. The ambrosioides, or oak of Cappadocia. All these are very easily propagated from seeds; and will thrive best in a rich light earth. Most of the species have an aromatic smell. A species which grows near the Mediterranean is used by the Egyptians in sallads, on account of its saltish aromatic taste. From the same plant, kelp is made in other countries. The first species, or English mercury, was formerly used as spinnach; but is now disused, as being greatly inferior to that herb. As an article of the materia medica, it is ranked among the emollient herbs, but rarely made use of in practice. The leaves are applied by the common people for healing slight wounds, cleansing old ulcers, and other like purposes. The roots are given to sheep that have a cough. Goats and sheep are not fond of the herb; cows, horses, and swine, refuse it.

CHEPELIO, an island in the bay of Panama and province of Darien, in South America, situated about

11 II

three

Chepflow
Chermes.

three leagues from the city of Panama, which it supplies with provisions. W. Long. 81°. N. Lat. 9°.
CHEPSTOW, a market-town of Monmouthshire in England, seated on the river Wye near its mouth, in W. Long. 2. 40. N. Lat. 51. 40.

CHEQ, or CHERIF, the prince of Mecca, who is, as it were, high priest of the law, and sovereign possessor of all the Mahometans of whatever sect or country they be. See CALIPH.

The grand signior, sophis, moguls, khans of Tartary, &c. send him yearly presents, especially tapestry to cover Mahomet's tomb withal, together with a sumptuous tent for himself, and vast sums of money to provide for all the pilgrims during the 17 days of their devotion.

CHERASCO, a strong and considerable town of Italy, in Piedmont, and capital of a territory of the same name, with a strong citadel belonging to the king of Sardinia, where he retired in 1706, during the siege of Turin. It is seated at the confluence of the rivers Sturia and Tanaro, upon a mountain. E. Long. 7. 55. N. Lat. 44. 35.

CHERBURG, a sea-port town of France, in Normandy, with a harbour and Augustine abbey. It is remarkable for the sea-fight between the English and French fleets in 1692, when the latter were beat, and upwards of twenty of their men of war burnt near Cape la Hogne. The British landed here in August 1758, and took the town, with the ships in the basin, demolished the fortifications, and ruined the other works which had been long carried on for enlarging the harbour and rendering it more safe and convenient. E. Long. 1. 38. N. Lat. 49. 38.

CHEREM, among the Jews, is used to signify a species of annihilation. See ANNIHILATION.

The Hebrew word *cherem*, signifies properly to "destroy, exterminate, devote, or anathematise."

CHEREM is likewise sometimes taken for that which is consecrated, vowed, or offered to the Lord, so that it may no longer be employed in common or profane uses. No devoted thing that a man shall devote unto the Lord, of all that he hath of man and beast, and of the field of his possession, shall be sold or redeemed; every devoted thing is most holy to the Lord: none devoted, which shall be devoted of men, shall be redeemed, but shall surely be put to death. There are some who assert that the persons thus devoted were put to death; whereof Jephtha's daughter is a memorable example. Judg. xi. 29, &c.

CHEREM is also used for a kind of excommunication in use among the Jews. See NIDDI.

CHERESOU, or CHARRZUL, a town of Turkey in Asia, capital of Kurdistan, and the seat of a beglerbeg. E. Long. 45. 15. N. Lat. 36. 0.

CHERILUS, of Samos, a Greek poet, flourished 479 years before Christ. He sung the victory gained by the Athenians over Xerxes, and was rewarded with a piece of gold for every verse. His poem had afterwards the honour of being rehearsed yearly with the works of Homer.

CHERLESQUIOR, in Turkish affairs, denotes a lieutenant general of the grand signior's armies.

CHERMES, in zoology, a genus of insects belonging to the order of insecta hemiptera. The rostrum

is situate on the breast; the feelers are longer than the breast; the four wings are deflected; the breast is gibbous; and the feet are of the jumping kind. There are 17 species; and the trivial names are taken from the plants which they frequent, as the chermes graminis, or grass-bug; the chermes ulmi, or elm-bug, &c.

CHERMES Mineral. See KERMES.

CHERRY-ISLAND, an island in the northern ocean, lying between Norway and Greenland, in E. Long. 20. 5. N. Lat. 75. 0.

CHERRY-Tree, in botany. See PRUNES.

CHERSO, an island in the gulph of Venice, with a town of the same name near Croatia, belonging to the Venetians. The air is good, but the soil stony; however, it abounds in wine, cattle, oil, and excellent honey. E. Long. 15. 5. N. Lat. 45. 8.

CHERSONESUS, among modern geographers, the same with a peninsula *. In ancient geography, it was applied to several peninsulas; as the Chersonesus Aurea, Cimbrica, Taurica, and Thracia, now thought to be Malacca, Jutland, Crim Tartary, and Romania. * See Peninsula.

CHERTSEY, a market-town of Surrey in England, about seven miles west from Kingston upon Thames. W. Long. 30°. N. Lat. 51. 25.

CHERUB, (plural, CHERUBIM); a celestial spirit, which in the hierarchy is placed next to the seraphim. See HIERARCHY.

The term *cherub* in Hebrew, is sometimes taken for a calf or ox. Ezekiel sets down the face of a cherub as synonymous to the face of an ox. The word *cherub* in Syriac and Chaldee, signifies to till or plow, which is the proper work of oxen. Cherub also signifies strong and powerful. Grotius says, that the cherubim were figures much like that of a calf. Borchart thinks likewise, that the cherubim were more like to the figure of an ox than to any thing besides; and Spencer is of the same opinion. Lastly, St John, in the Revelations, calls cherubim *beasts*. Josephus says, the cherubim were extraordinary creatures, of a figure unknown to mankind. Clemens of Alexandria believes, that the Egyptians imitated the cherubim of the Hebrews in the representations of their sphinxes and their hieroglyphical animals. All the several descriptions which the Scripture gives us of cherubim differ from one another; but all agree in representing them as a figure composed of various creatures, as a man, an ox, an eagle, and a lion. Such were the cherubim described by Ezekiel. Those which Isaiah saw, and are called *seraphim* by him, had the figure of a man with six wings; with two whereof they covered their faces, with two more they covered their feet, and with the two others they flew. Those which Solomon placed in the temple of Jerusalem, are supposed to have been nearly of the same form. Those which St John describes in the Revelations, were all eyes before and behind, and had each six wings. The first was in the form of a lion, the second in that of a calf, the third of a man, and the fourth of an eagle. The figure of the cherubim was not always uniform, since they are differently described in the shapes of men, eagles, oxen, lions, and in a composition of all these figures put together. Moses likewise calls these symbolical or hieroglyphical representations, which were embroidered on the veils

Chermes
Cherub.

Chervil
Cheine.

of the tabernacle, *cherubim* of costly work. Such were the symbolical figures which the Egyptians placed at the gates of their temples, and the images of the generality of their gods, which were commonly nothing but statues composed of men and animals.

CHERVIL, in botany. See **CEROPHYLLUM**.

CESHIRE, a maritime county of England, bounded by Lancashire on the north; Shropshire and part of Flintshire, on the south; Derbyshire and Staffordshire, on the east and south-east; and Denbighshire, and part of Flintshire, on the west and north-west. It extends in length about 44 miles, in breadth 25; and is supposed to contain 125,000 inhabitants. Both the air and soil in general are good. In many places of the country are peat-mosses, in which are often found trunks of fir-trees, sometimes several feet under ground, that are used by the inhabitants both for fuel and candles. Here also are many lakes and pools well stored with fish; besides the rivers Mersey, Weaver, and Dee, which last falls into a creek of the Irish sea near Chester. This county also abounds with wood; but what it is chiefly remarkable for, is its cheese, which has a peculiar flavour, generally thought not to be inferior to any in Europe. Many conjectures have been formed concerning the reason of this flavour; but Dr Campbell *, with great probability, ascribes it to the salt-rocks which abound here, and of which a great quantity is annually sent to Liverpool, to be there manufactured into salt. As a proof of this, he tells us, that as the brine-spring at Namptwich is the richest in the whole county, and produces the fairest salt; so the town and its neighbourhood is remarkable for the best cheese in all Cheshire. The principal towns are Chester the capital, Cholmondeley, Namptwich, &c.

William the Conqueror erected this county into a palatinate, or county-palatine, in favour of his nephew Hugh Lupus, to whom he granted the same sovereignty and jurisdiction in it that he himself had in the rest of the island. By virtue of this grant, the town of Chester enjoyed sovereign jurisdiction within its own precincts; and that in so high a degree, that the earls held parliaments, consisting of their barons and tenants, which were not bound by the acts of the English parliament: but this exorbitant power of the palatinates was at last reduced by Henry VIII.; however, all cases and crimes, except those of error, foreign-plea, foreign-voucher, and high-treason, are still heard and determined within the shire. The earls were anciently superiors of the whole county, and all the land-holders were mediately or immediately their vassals, and under the like sovereign allegiance to them as they were to the kings of England; but the earldom was united to the crown by Edward III. since which time, the eldest sons of kings of England have always been earls of Chester, as well as princes of Wales. Cheshire sends four members to parliament; two for the county, and two for the capital.

CHESNE (Andrew du), styled the father of French history, was born in 1584. He wrote, 1. A history of the popes. 2. An history of England. 3. An inquiry into the antiquities of the towns of France. 4. An history of the cardinals. 5. A bibliotheca of the authors who have written the history and topogra-

phy of France, &c. He was crushed to death by a cart, in going from Paris to his country-house at Verriere, in 1640.

CHESNUT-TREE. See **FAGUS**.

CHESSE, an ingenious game performed with different pieces of wood, on a board divided into 64 squares or houses; in which chance has so small a share, that it may be doubted whether a person ever lost a game but by his own fault.

Each gamester has eight dignified pieces, *viz.* a king, a queen, two bishops, two knights, and two rooks, also eight pawns: all which, for distinction's sake, are painted of two different colours, as white and black.

As to their disposition on the board, the white king is to be placed on the fourth black house from the corner of the board, in the first and lower rank; and the black king is to be placed on the fourth white house on the opposite, or adversary's end of the board. The queens are to be placed next to the kings, on houses of their own colour. Next to the king and queen, on each hand, place the two bishops; next to them, the two knights; and last of all, on the corners of the board, the two rooks. As to the pawns, they are placed without distinction, on the second rank of the house, one before each of the dignified pieces.

Having thus disposed the men, the onset is commonly begun by the pawns, which march straight forward in their own file, one house at a time; except the first move, when it can advance two houses, but never moves backwards: the manner of their taking the adversary's men, is side-ways, in the next house forwards; where having captivated the enemy, they move forward as before. The rook goes forward or cross-ways through the whole file, and back again. The knight skips backward and forward to the next house, save one, of a different colour, with a sidling march, or a slope, and thus kills his enemies that fall in his way, or guards his friends that may be exposed on that side. The bishop walks always in the same colour of the field that he is placed in at first, forward and backward, alope, or diagonally, as far as he lists. The queen's walk is more universal, as she takes all the steps of the before mentioned pieces, excepting that of the knight; and as to the king's motion, it is one house at a time, and that, either forward, backward, sloping, or side-ways.

As to the value of the different pieces, next to the king is the queen, after her the rooks, then the bishops, and last of the dignified pieces comes the knight. The difference of the worth of pawns, is not so great as that of noblemen; only, it must be observed, that the king's bishop's pawn is the best in the field, and therefore the skilful gamester will be careful of him. It ought also to be observed, that whereas any man may be taken, when he falls within the reach of any of the adversary's pieces, it is otherwise with the king, who, in such a case, is only to be saluted with the word *check*, warning him of his danger, out of which it is absolutely necessary that he move; and, if it so happen that he cannot move without exposing himself to the like inconveniency, it is check-mate, and the game is lost.

Sarrafin has an express treatise on the different opi-

Chest
1
Chest.

nions of the origin of the Latin *schacchi*, whence the French *ethes*, and our *chess*, is formed. Menage is also very full on the same head. Leunclavius takes it to come from *Ufcoches*, famous Turkish robbers: P. Sirmond, from the German *schachze*, "theft;" and that from *calculus*. He takes *chess* to be the same with the *ludus latruncularum* of the Romans, but mistakenly. This opinion is countenanced by Vossius and Salmasius, who derive the word from *calculus*, as used for *latrunculus*. G. Tolofanus derives it from the Hebrew, *schach*, *vallavit et mat mortuus*; whence *check* and *check-mate*. Fabricius says, a celebrated Persian astronomer, one Schatrenschia, invented the game of *chess*; and gave it his own name, which it still bears in that country. Nicod derives it from *schogue*, or *seque*, a Moorish word for lord, king, and prince. Bochart adds, that *schach* is originally Persian; and that *schachmat*, in that language, signifies the king is dead.—The opinion of Nicod and Bochart, which is likewise that of Scriverius, appears the most probable.

Dionatus, on Terence's *Eunuch*, observes, that Pyrrhus, the most knowing and expert prince of his age at ranging a battle, made use of the men at *chess* to form his designs, and to shew the secrets thereof to others. Vopiscus, in his life of Proculus, informs us, that one of the Roman emperors had the title Augustus given him, because of his gaining ten games at *chess* successively. Tamerlane is recorded as a very expert gambler at *chess*.—*Chess* is doubtless a most ancient and universal game: the common opinion is, that it was invented by Palamedes at the siege of Troy. Others attribute the invention to Diomedes, who lived in the time of Alexander: the romance of the Rose ascribes it to one Attalus; but the truth is, the game is so very ancient, there is no tracing its author. In China, it makes a considerable part of the education of their maids; and seems to take the place of dancing among us. In Spain, whole cities challenge each other at *chess*. John of Salisbury relates, that in a battle between the French and English in 1117, an English knight seizing the bridle of Louis le Gros, and crying to his comrades, *The king is taken*, that prince struck him to the ground with his sword, saying, *Ne seais tu pas qu' aux echecs on ne prend pas le roy*? "Dost thou not know, that at *chess* the king is never taken?" The reason is, that when the king is reduced to such a pass that there is no way for him to escape, the game ends, without exposing the royal piece to further affront.

Cardinal Cajetan, and other casuists, rank *chess* in the number of prohibited games, as requiring too much application: and Montaign blames it as too serious for a game.

CHESS-TREES, *taquets d'anire*; two pieces of wood bolted perpendicularly, one on the starboard, and another on the larboard side of the ship. They are used to confine the *clue*, or lower corners of the main-sail; for which purpose there is a hole in the upper part, through which the rope passes that usually extends the clue of the sail to windward. See **TACK**.

The chess-trees are commonly placed as far before the main-mast as the length of the main-beam.

CHEST, in commerce, a kind of measure, containing an uncertain quantity of several commodities.

A chest of sugar, *v. g.* contains from ten to fifteen hundred weight; a chest of glass, from two hundred to three hundred feet; of Castile soap, from two and an half to three hundred weight; of indigo, from one and an half to two hundred weight, five score to the hundred.

CHEST, or *Thorax*, in anatomy. See there, Part V.

CHESTER, commonly called *West-Chester*, to distinguish it from many other Chesters in the kingdom; the capital of Cheshire, in England. It is a very ancient city, supposed to have been founded by the Romans; and plainly appears to have been a Roman station by the many antiquities which have been and are still discovered in and about the town. It was among the last places the Romans quitted; and here the Britons maintained their liberty long after the Saxons had got possession of the rest of their country. At present it is a large well-built wealthy city, and carries on a considerable trade. Mr Pennant calls it "a city without parallel," on account of the singular structure of the four principal streets. They are as if excavated out of the earth, and sunk many feet beneath the surface: the carriages drive far beneath the level of the kitchens, on a line with ranges of shops. The houses are mostly of wood, with galleries, piazzas, and covered walls before them, by which not only the shops, but those who are walking about the town, are so hid, that one would imagine there were scarce any inhabitants in it, though it is very populous. But though by this contrivance, such as walk the streets are screened from rain, &c. yet the shops are thereby rendered dark and inconvenient. The back courts of all the houses are on a level with the ground; but to go into any of the four principal streets, it is necessary to descend a flight of several steps. W. Long. 3. 0. N. Lat. 53. 12.

NEW CHESTER, a town of Pennsylvania in America, and capital of a county of that name. It is seated on the Delaware; and has a fine capacious harbour, admitting vessels of any burthen. W. Long. 74. 7. N. Lat. 40. 15.

CHESTERFIELD, a market-town of Derbyshire in England, pleasantly situated on a hill between two small rivers. It has the title of an earldom; and a considerable market for corn, lead, and other country commodities. The houses are, for the most part, built of rough stone, and covered with slate. W. Long. 1. 25. N. Lat. 53. 20.

CHESTERFIELD (Earl of.) See **STANHOPE**.

CHEVAL DE FRISE, a large piece of timber pierced, and traversed with wooden spikes, armed or pointed with iron, five or six feet long. See Plate LXXXIV. fig. 8.

The term is French, and properly signifies a *Friesland horse*; as having been first invented in that country.—It is also called a *Turnpike* or *Turniquet*. See **TURNPIKE**.

Its use is to defend a passage, stop a breach, or make a retrenchment to stop the cavalry. It is sometimes also mounted on wheels, with artificial fires, to roll down in an assault. Errard observes, that the prince of Orange used to inclose his camp with *Chevaux de Frise*, placing them one over another.

CHEVALER,

Chest
1
Cheval.

Chevalier
|
Clayne.

CHEVALER, in the menage, is said of a horse, when, in passing upon a walk or trot, his off fore-leg crosses or overlaps the near fore-leg every second motion.

CHEVALIER, a French term, ordinarily signifying a knight. See KNIGHT. The word is formed of the French *cheval*, "horse;" and the barbarous Latin *caualis*.

It is used, in heraldry, to signify any *cavalier*, or horseman armed at all points; by the Romans called *cataphractus equus*: now out of use, and only to be seen in coat-armour.

CHEVAUX DE FRISE. See CHEVAL *de Frise*.

CHEVIN, a name used in some parts of England for the CHUB.

CHEVIOT, (or TIVIOT) HILLS, run from north to south through Cumberland; and were formerly the borders or boundaries between England and Scotland, where many a bloody battle has been fought between the two nations; one of which is recorded in the ballad of Chevy-chase. See CHASE.

CHEVISANCE, in law, denotes an agreement or composition, as an end or order set down between a creditor and his debtor, &c. In the statutes, this word is most commonly used for an unlawful bargain or contract.

CHEVREAU (Urban), a learned writer, born at Lundun in 1613. He distinguished himself in his youth by his knowledge of the belles lettres; and became secretary of state to queen Christina of Sweden. Several German princes invited him to their courts; and Charles-Lewis, the elector palatine, retained him under the title of counsellor. After the death of that prince, he returned to France, and became preceptor to the duke of Maine. At length retiring to Lundun, he died there in 1701, aged 88. He was the author of several books; and amongst others, of an Universal History, which has been often reprinted.

CHEVRON, or CHEVERON, in heraldry. See there, n° 23, 24.

CHEWING-BALLS, a kind of balls made of asafetida, liver of antimony, bay-wood, juniper-wood, and pelltury of Spain; which being dried in the sun, and wrapped in a linen cloth, are tied to the bit of the bridle for the horse to chew: they create an appetite; and it is said, that balls of Venice-treacle may be used in the same manner with good success.

CHEYKS. See BENGAL, n° 6.

CHEYNE (Dr George), a physician of great learning and abilities, born in Scotland in 1671, and educated at Edinburgh under the great Dr Pricairn. He passed his youth in close study, and with great temperance: but coming to settle at London, when about 30, and finding the younger gentry and free-livers to be the most easy of access and most susceptible of friendship, he changed on a sudden his former manner of living in order to force a trade, having observed this method to succeed with some others. The consequence was, that he grew daily in bulk, and in intimacy with his gay acquaintance; swelling to such an enormous size, that he exceeded 32 stone weight; and he was forced to have the whole side of his chariot made open to receive him into it: he grew short-breathed, lethargic, nervous, and scorbutic; so that

his life became an intolerable burden. In this deplorable condition, after having tried all the power of medicine in vain, he resolved to try a milk and vegetable diet: the good effects of which quickly appeared. His size was reduced almost a third; and he recovered his strength, activity, and cheerfulness; with the perfect use of all his faculties. In short, by a regular adherence to this regimen, he lived to a mature period, dying at Bath in 1748, aged 77. He wrote several treatises that were well received; particularly, "an essay on Health and Long Life;" and "the English Malady, or a treatise of Nervous Diseases;" both the result of his own experience.

CHIABRERA (Gabriel), esteemed the Pindar of Italy, was born at Savona in 1552, and went to study at Rome. The Italian princes, and Urban VIII. gave him public marks of their esteem. He wrote a great number of poems; but his lyric verses are most admired. He died at Savona in 1638, aged 86.

CHIAN EARTH, in pharmacy, one of the medicinal earths of the ancients, the name of which is preserved in the catalogues of the materia medica, but of which nothing more than the name has been known for many ages in the shops.

It is a very dense and compact earth; and is sent hither in small flat pieces from the island of Chios, in which it is found in great plenty at this time. It stands recommended to us as an astringent. They tell us, it is the greatest of all colimetics; and that it gives a whiteness and smoothness to the skin, and prevents wrinkles, beyond any of the other substances that have been celebrated for the same purposes.

CHIAOUS, a word in the original Turkish, signifying "envoys," are officers to the number of five or six hundred in the grand signior's court, under the command of a *chiaous bashi*. They frequently meet in the grand vizier's palace, that they may be in readiness to execute his orders, and carry his dispatches into all the provinces of the empire. The *chiaous bashi* assists at the divan, and introduces those who have business there.

CHIAPA, the capital of a province of the same name in Mexico, situated about 300 miles east of Acapulco. W. Long. 98. o. N. Lat. 16. 30.

CHIAPA *el Real*, a town of North America, in Mexico, a province of the same name, with a bishop's see. Its principal trade consists in chocolate-nuts, cotton, and sugar. W. Long. 98. 35. N. Lat. 16. 20.

CHIAPAS *de los Indes*, a large and rich town of North America, in Mexico, and in a province of the same name. The governor and most of the inhabitants are originally Americans. W. Long. 98. 5. N. Lat. 15. 6.

CHIARI (Joseph), a celebrated Italian painter, was the disciple of Carlo Maratti; and adorned the churches and palaces of Rome with a great number of fine paintings. He died of an apoplexy in 1727, aged 73.

CHIARI, a town of Italy, in the province of Brescia, and territory of Venice, 7 miles west of Brescia, and 27 east of Milan. Here the Imperialists gained a victory over the French in 1701. E. Long. 18. 18. N. Lat. 45. 30.

CHIARO-SCURO. See CHIARO-*Oscurro*.

CHIAVENNA, a handsome, populous, and large town

Chiabrera
|
Chiavenna.

Chief
|
Chief.

town of Switzerland, in the country of the Grisons. It is a trading place, especially in wine and delicate fruits. The governor's palace, and the churches, are very magnificent, and the inhabitants are Roman Catholics. It is seated near the lake Como. E. Long. 9. 29. N. Lat. 46. 15.

CHIAUSI, among the Turks, officers employed in executing the vizirs, bashaws, and other great men: the orders for doing this, the grand signior sends them wrapped up in a black cloth; on the reception of which, they immediately perform their office.

CHICANE, or CHICANERY, in law, an abuse of judiciary proceeding, tending to delay the cause, to puzzle the judge, or impose upon the parties.

CHICANE, in the schools, is applied to vain sophisms, distinctions, and subtleties, which protract disputes, and obscure the truth.

CHICHESTER, the capital city of the county of Suffex, is surrounded with a wall, which has four gates, answering to the four cardinal points; from which run two streets, that cross one another in the middle and form a square, where the market is kept, and where there is a fine stone piazza built by bishop Read. The space between the west and south gates is taken up with the cathedral church and the bishop's palace. It has five parish-churches; and is seated on the little river Lavant, which washes it on all sides except the north. This city would have been in a much more flourishing condition if it had been built by the sea-side; however, the inhabitants have endeavoured to supply this defect in some measure by cutting a canal from the city down into the bay. The principal manufactures of the town are malt and needles. The market of Chichester is noted for fish, wheat, barley, malt, and oats: the finest lobsters in England are bred in the Lavant; and it is observable, that this river, unlike most others, is very low in winter, but in summer often overflows its banks. Chichester is a city and a county of itself; the government being vested in a mayor, recorder, aldermen, common-council without limitation, and four justices of the peace chosen out of the aldermen. It is a bishop's see, and sends two members to parliament. W. Long. 50. N. Lat. 50. 50.

CHICK, or CHICKEN, in zoology, denotes the young of the gallinaceous order of birds, especially the common hen. See PHASIANUS.

CHICKEN-Pox. See (Index subjoined to) MEDICINE.

CHICK-Weed, in botany. See ALSINE.

CHICKLING-PEA, in botany, a name given to the LATYRUS.

CHICUITOS, a province of South America, in the government of Santo-Cruz de la Sierra. The chief riches consist of honey and wax; and the original inhabitants are very voluptuous, yet very warlike. They maintained bloody wars with the Spaniards till 1690; since which, some of them have become Christians. It is bounded by la Plata on the N. E. and by Chili on the W.

CHIDLEY, or CHIMLEY, a market-town of Devonshire, situated in W. Long. 4. o. N. Lat. 51. o.

CHIEF, a term signifying the head or principal part of a thing or person. Thus we say, the chief of a

party, the chief of a family, &c. The word is formed of the French *chef*, "head;" of the Greek *κεφαλη*, *caput*, "head;" though Menage derives it from the Italian *capo*, formed of the Latin *caput*.

CHIEF, in heraldry, is that which takes up all the upper part of the escutcheon from side to side, and represents a man's head: see HERALDRY, n° 15.—In *chief*, imports something borne in the chief part or top of the escutcheon.

CHIEFTAIN, denotes the captain or chief of any class, family, or body of men. Thus the chieftains or chiefs of the Highland clans, were the principal noblemen or gentlemen of their respective clans. See CLANS.

CHIELEFA, a strong town of Turkey in Europe, in the Morea. It was taken by the Venetians in 1685; but after that the Turks retook it, with all the Morea. E. Long. 22. 21. N. Lat. 26. 50.

CHILBLAIN, (*pernio*), in medicine, a tumour affecting the feet and hands; accompanied with an inflammation, pains, and sometimes an ulcer or solution of continuity: in which case it takes the denomination of *chaps* on the hands, and of *kibes* on the heels. Chilblain is compounded of *chill* and *blain*; *q. d.* a blain or sore contracted by cold. *Pernio* is the Latin name adopted by physicians; and is derived by Vossius from *perna* "a gammon of bacon," on account of some resemblance. *Chap* alludes to *gape*, both in sound and appearance. *Kibes*, in Welsh *kibws*, may be derived from the German *kerben*, "to cut;" the skin, when broke, appearing like a cut.

Chilblains are occasioned by excessive cold stopping the motion of the blood in the capillary arteries. See the article PERNIO.

CHILD, a term of relation to *parent*. See PARENT and CHILDREN.

Bartholine, Paré, Licetus, and many other writers, give an account of a petrified child, which has seemed wholly incredible to some people. The child, however, which they describe, is still in being; and is kept as a great rarity in the king of Denmark's museum at Copenhagen. The woman who was big with this, lived at Sens in Champaign in the year 1582; it was cut out of her belly, and was universally supposed to have lain there about 20 years. That it is a real human fetus, and not artificial, is evident to the eyes of any observer; and the upper part of it, when examined, is found to be of a substance resembling the gypsum, or stone whereof they make the plaster of Paris: the lower part is much harder; the thighs and buttocks being a perfect stone of a reddish colour, and as hard as common quarry-stone: the grain and surface of this part appears exactly like that of the calculi, or stones taken out of human bladders; and the whole substance examined ever so nearly, and felt ever so carefully, appears to be absolute stone. It was carried from Sens to Paris, and there purchased by a goldsmith of Venice; and Frederic III. king of Denmark, purchased it of this man at Venice for a very large sum, and added it to his collection of rarities.

CHILD-Bed, } See MIDWIFERY.
CHILD-Birth. }

CHILD-Wit, a power to take a fine of a bond-woman

Chief
|
Child-wit.

man unlawfully gotten with child, that is, without consent of her lord. Every reputed father of a base child got within the manor of Writtle in Essex, pays to the lord a fine of 3*s.* 4*d.*; where, it seems, child-wit extends to free, as well as bond women.

CHILDERMAS'-DAY, or INNOCENTS'-Day, an anniversary held by the church of England on the 28th of December, in commemoration of the children of Bethlehem massacred by order of Herod.

CHILDREN, the plural of CHILD.

Mr Derham computes, that marriages, one with another, produce four children, not only in England, but in other parts also.

In the genealogical history of Tuscany, wrote by Gamarini, mention is made of a nobleman of Sienna, named Pichi, who of three wives had 150 children; and that, being sent ambassador to the pope and the emperor, he had 48 of his sons in his retinue. In a monument in the church-yard of St Innocent, at Paris, erected to a woman who died at 88 years of age, it is recorded, that she might have seen 288 children directly issued from her. This exceeds what Hake-well relates of Mrs Honeywood, a gentlewoman of Kent, born in the year 1527, and married at 16 to her only husband R. Honeywood, of Charing, Esq; and died in her 93^d year. She had 16 children of her own body; of which three died young, and a fourth had no issue: yet her *grandchildren*, in the second generation, amounted to 114; in the third, to 228; though in the fourth, they fell to 9. The whole number she might have seen in her life-time being 367. 16+114+228+9=367. So that she could say the same as the distich does of one of the Dalburg's family at Basil:

1 2 3 4
Mater ait natæ dic natæ filia nata,
 5 6

Ut moneat, natæ, plangere, liliam.

Management of CHILDREN. See INFANT.

Overlaying of CHILDREN, is a misfortune that frequently happens; to prevent which the Florentines have contrived an instrument called *arcuccio*. See ARCUCCIO.

CHILDREN ARE, in law, a man's issue begotten on his wife. As to *illegitimate children*, see BASTARD.

For the legal duties of parents to their children, see PARENT and BASTARD.

As to the duties of children to their parents, they arise from a principle of natural justice and retribution. For to those who gave us existence, we naturally owe subjection and obedience during our minority, and honour and reverence ever after: they who protected the weakness of our infancy, are intitled to our protection in the infirmity of their age; they who by sustenance and education have enabled their offspring to prosper, ought, in return, to be supported by that offspring, in case they stand in need of assistance. Upon this principle proceed all the duties of children to their parents, which are enjoined by positive laws. And the Athenian laws carried this principle into practice with a scrupulous kind of nicety: obliging all children to provide for their father when fallen into poverty; with an exception to spurious children, to those whose chastity had been prostituted

with consent of their father, and to those whom he had not put in any way of gaining a livelihood. The legislature, says baron Montesquieu, considered, that, in the first case, the father, being uncertain, had rendered the natural obligation precarious; that, in the second case, he had sullied the life he had given, and done his children the greatest of injuries, in depriving them of their reputation; and that, in the third case, he had rendered their life, (so far as in him lay), an insupportable burden, by furnishing them with no means of subsistence.

Our laws agree with those of Athens, with regard to the first only of these particulars, the case of spurious issue. In the other cases, the law does not hold the tie of nature to be dissolved by any misbehaviour of the parent; and therefore a child is equally justifiable in defending the person, or maintaining the cause or suit, of a bad parent, as of a good one; and is equally compellable, if of sufficient ability, to maintain and provide for a wicked and unnatural progenitor, as for one who has shewn the greatest tenderness and parental piety.

CHILI, a province of South America, bounded by Peru on the north, by the province of La Plata on the east, by Patagonia on the south, and by the Pacific ocean on the west, lying between 75 and 85 degrees of west longitude, and between 25 and 45 degrees of south latitude; though some comprehend in this province, Patagonia and Terra del Fuego.

The first attempt of the Spaniards upon this country was made by Almagro in the year 1535, after he and Pizarro had completed the conquest of Peru. He set out on his expedition to Chili with a considerable body of Spaniards and auxiliary Indians. For 200 leagues, he was well accommodated with every necessary by the Indians, who had been subjects of the emperors of Peru: but reaching the barren country of Charcas, his troops became discontented through the hardships they suffered; which determined Almagro to climb the mountains called Cordilleras, in order to get the sooner into Chili; being ignorant of the invaluable mines of Potosi, contained in the province of Charcas where he then was. At that time the Cordilleras were covered with snow, the depth of which obliged him to dig his way through it. The cold made such an impression on his naked Indians, that it is computed no less than 10,000 of them perished on these dreadful mountains, 150 of the Spaniards sharing the same fate; while many of the survivors lost their fingers and toes through the excess of cold. At last, after encountering incredible difficulties, Almagro reached a fine, temperate, and fertile plain on the opposite side of the Cordilleras, where he was received with the greatest kindness by the natives. These poor savages, taking the Spaniards for deputies of their god Virachoca, immediately collected for them an offering of gold and silver worth 200,000 ducats: and soon after brought a present to Almagro worth 300,000 more. These offerings only determined him to conquer the whole country as soon as possible. The Indians among whom he now was, had acknowledged the authority of the Peruvian incas, or emperors, and consequently gave Almagro no trouble. He therefore marched immediately against those who had never been

been conquered by the Peruvians, and inhabited the southern parts of Chili. These savages fought with great resolution, and disputed every inch of ground : but in five months time the Spaniards had made such progress, that they must infallibly have reduced the whole province in a very little time, had not Almagro returned to Peru, in consequence of a commission sent him from Spain.

In 1540, Pizarro having overcome and put Almagro to death, sent into Chili, *Baldivia*, or *Valdivia*, who had learned the rudiments of war in Italy, and was reckoned one of the best officers in the Spanish service. As he penetrated southwards, however, he met with much opposition : the confederated caziques frequently gave him battle, and displayed great courage and resolution ; but could not prevent him from penetrating to the valley of *Mafisco*, which he found incredibly fertile and populous. Here he founded the city of St Jago ; and finding gold mines in the neighbourhood, forced the Indians to work in them ; at the same time building a castle for the safety and protection of his new colony. The natives, exasperated at this slavery, immediately took up arms ; attacked the fort ; and, though defeated and repulsed, set fire to the outworks, which contained all the provisions of the Spaniards. Nor were they discouraged by this and many other defeats, but still continued to carry on the war with vigour. At last, Valdivia, having overcome them in many battles, forced the inhabitants of the vale to submit ; upon which he immediately let them to work in the mines of Quilotes. This indignity offered to their countrymen redoubled the fury of those who remained at liberty. Their utmost efforts, however, were as yet unable to stop Valdivia's progress. Having crossed the large rivers Maule and Hata, he travelled a vast tract of country, and founded the city of *La Concepcion* on the South-sea-coast. He erected fortresses in several parts of the country, in order to keep the natives in awe ; and built the city called *Imperial*, about 40 leagues to the southward of Concepcion. The Spanish writers say, that the neighbouring valley contained 80,000 inhabitants of a peaceable disposition ; and who were even so tame as to suffer Valdivia to parcel out their lands among his followers, while they themselves remained in a state of inactivity. About 16 leagues to the eastward of *Imperial*, the Spanish general laid the foundations of the city *Villa Rica*, so called on account of the rich gold mines he found there. But his ambition and avarice had now involved himself in difficulties from which he could never be extricated : He had extended his conquests beyond what his strength was capable of maintaining. The Chileans were still as desirous as ever of recovering their liberties. The horses, fire-arms, and armour of the Spaniards, indeed, appeared dreadful to them ; but the thoughts of endless slavery were still more so. In the course of the war they had discovered that the Spaniards were vulnerable and mortal men like themselves ; they hoped, therefore, by dint of their superiority in numbers, to be able to expel the tyrannical usurpers. Had all the nations joined in this resolution, the Spaniards had certainly been exterminated ; but some of them were of a pacific and fearful disposition, while others considered servitude as the greatest of all possible calamities.

Of this last opinion were the *Araceans*, the most intrepid people in Chili, and who had given Valdivia the greatest trouble. They all rose to a man, and chose *Capaulcan*, a renowned hero among them, for their leader. Valdivia, however, received notice of their revolt sooner than they intended he should, and returned with all expedition to the vale of Aracea ; but before he arrived, 14,000 of the Chileans were there assembled under the conduct of Capaulcan. He attacked them with his cavalry, and forced them to retreat into the woods ; but could not obtain a complete victory, as they kept continually falling out and harassing his men. At last Capaulcan, having observed that fighting with such a number of undisciplined troops only served to contribute to the defeat and confusion of the whole, divided his forces into bodies of 1000 each. These he directed to attack the enemy by turns ; and, though he did not expect that a single thousand would put them to flight, he directed them to make as long a stand as they could ; when they were to be relieved and supported by another body ; and thus the Spaniards would be at last wearied out and overcome. The event fully answered his expectations. The Chileans maintained a fight for seven or eight hours, until the Spaniards, growing faint for want of refreshment, retired precipitately. Valdivia ordered them to possess a pass at some distance from the field, to stop the pursuit ; but this design being discovered to the Chilkians by the treachery of his page, who was a native of that country, the Spaniards were surrounded on all sides, and cut in pieces by the Indians. The general was taken and put to death ; some say with the tortures usually inflicted by those savages on their prisoners* ; others, that he had melted gold poured down his throat ; but all agree, that the Indians made flutes and other instruments of his bones, and preserved his skull as a monument of their victory, which they celebrated by an annual festival. After this victory the Chileans had another engagement with their enemies ; in which also they proved victorious, defeating the Spaniards with the loss of near 3000 men ; and upon this they bent their whole force against the colonies. The city of Concepcion, being abandoned by the Spaniards, was taken and destroyed ; but the Indians were forced to raise the siege of *Imperial* ; and their progress was at last stopped by Garcia de Mendoza, who defeated Capaulcan, took him prisoner, and put him to death. No defeats, however, could dispirit the Chileans. They continued the war for 50 years ; and to this day they remain unconquered, and give the Spaniards more trouble than any other American nation. Their most irreconcilable enemies are the inhabitants of Aracea and Tucapel, those to the south of the river Bobio, or whose country extends towards the Cordilleras.—The manners of these people greatly resemble those of North America, which we have already described under the article AMERICA ; but seem to have a more warlike disposition. It is a constant rule with the Chileans never to sue for peace. The Spaniards are obliged not only to make the first overtures, but to purchase it by presents. They have at last been obliged to abandon all thoughts of extending their conquests, and reduced to cover their frontiers by erecting forts at proper distances.

* See America, n^o 35.

Chili.

The Spanish colonies in Chili are dispersed on the borders of the South-sea. They are parted from Peru by a desert 80 leagues in breadth; and bounded by the island of Chiloe, at the extremity next the straits of Magellan. There are no settlements on the coast except those of Baldivia, Concepcion-island, Valparaíso, and Coquimbo or La Serena, which are all sea-ports. In the inland country is St Jago, the capital of the colony. There is no culture nor habitation at any distance from these towns. The buildings in the whole province are low, made of unburnt brick, and mostly thatched. This practice is observed on account of the frequent earthquakes; and is properly adapted to the nature of the climate, as well as the indolence of the inhabitants.

The climate of Chili is one of the most wholesome in the whole world. The vicinity of the Cordilleras gives it such a delightful temperature as could not otherwise be expected in that latitude. Though gold mines are found in it, their richness has been too much extolled; their produce never exceeds L. 218,750. The soil is prodigiously fertile. All the European fruits have improved in that happy climate. The wine would be excellent if nature were properly assisted by art: and the corn-harvest is reckoned a bad one when it does not yield a hundred fold. With all these advantages, Chili has no direct intercourse with the mother-country. Their trade is confined to Peru, Paraguay, and the savages on their frontiers. With these last they exchange their less valuable commodities, for oxen, horses, and their own children, whom they are ready to part with for the most trifling things. This province supplies Peru with great plenty of hides, dried fruit, copper, salt-meat, horses, hemp, lard, wheat, and gold. In exchange it receives tobacco, sugar, cocoa, earthen-ware, woollen-cloth, linen, hats made at Quito, and every article of luxury brought from Europe. The ships sent from Callao on this traffic were formerly bound to Concepcion Bay, but now come to Valparaíso. The commerce between this province and Paraguay is carried on by land, though it is a journey of 300 leagues, 40 of which lie through the snows and precipices of Cordilleras; but if it was carried on by sea, they must either pass the straits of Magellan, or double Cape Horn, which the Spaniards always avoid as much as possible. To Paraguay are sent some woollen stuffs called *ponchos*, which are used for cloaks; also wines, brandy, oil, and chiefly gold. In return they receive wax, a kind of tallow fit to make soap, European goods, and negroes.

Chili is governed by a chief, who is absolute in all civil, political, and military affairs, and is also independent of the viceroy. The latter has no authority except when a governor dies; in which case he may appoint one in his room for a time, till the mother-country names a successor. If, on some occasions, the viceroy has interfered in the government of Chili, it was when he has been either authorized by a particular trust reposed in him by the court, or by the deference paid to the eminence of his office; or when he has been actuated by his own ambition to extend his authority. In the whole province of Chili there are not 20,000 white men, and not more than 60,000 ne-

VOL. III.

grees, or Indians, able to bear arms. The military establishment amounted formerly to 2000 men; but the maintaining of them being found too expensive, they were reduced to 500 at the beginning of this century.

CHILIAD, an assemblage of several things ranged by thousands. The word is formed of the Greek *χίλιας*, *millē*, a thousand.

CHILIARCHA, or CHILIARCHUS, an officer in the armies of the ancients, who had the command of a thousand men.

CHILIAGON, in geometry, a regular plain figure of 100 sides and angles. Though the imagination cannot form the idea of such a figure, yet we may have a very clear notion of it in the mind, and can easily demonstrate that the sum of all its angles is equal to 1996 right ones: for the internal angles of every plane figure are equal to twice as many right ones as the figure hath sides, except those four which are about the centre of the figure, from whence it may be resolved into as many triangles as it has sides. The author of *L'art de Penfer*, p. 44. has brought this instance to shew the distinction between imagination and conceiving.

CHILIASTS, in church-history See MILLENA-RIANS.

CHILLINGWORTH (William), an eminent divine of the church of England, was born at Oxford in 1602, and bred there. He made early great proficiency in his studies, being of a very quick genius. He was an expert mathematician, as well as an able divine, and a very good poet. Study and conversation at the university turning upon the controversy between the church of England and that of Rome, on account of the king's marriage with Henrietta daughter to Henry IV. king of France, Mr Chillingworth forsook the church of England, and embraced the Romish religion. Dr Laud, then bishop of London, hearing of this, and being greatly concerned at it, wrote Mr Chillingworth; who expressing a great deal of candour and impartiality, that prelate continued to correspond with him. This set Mr Chillingworth on a new inquiry; and at last determined him to return to his former religion. In 1634 he wrote a confutation of the arguments which had induced him to go over to the church of Rome. He spoke freely to his friends of all the difficulties that occurred to him; which gave occasion to a groundless report, that he had turned Papist a second time, and then Protestant again. His return to the communion of the church of England made a great noise, and engaged him in several disputes with those of the Romish persuasion. But in 1635 he engaged in a work which gave him a far greater opportunity to confute the principles of the church of Rome, and to vindicate the Protestant religion, under the title of "The Religion of Protestants a safe Way to Salvation." Sir Thomas Coventry, lord keeper of the great seal, offering him preferment, Mr Chillingworth refused to accept it on account of his scruples with regard to the subscription of the 39 articles. However he at last surmounted these scruples; and being promoted to the chancellorship of the church of Sarum, with the prebend of Brixworth in Northamptonshire annexed to it, he com-

plied with the usual subscription. Mr Chillingworth was zealously attached to the royal party; and, in August 1643, was present in king Charles I.'s army at the siege of Gloucester, where he advised and directed the making certain engines for assaulting the town. Soon after, having accompanied the Lord Hopton, general of the king's forces in the west, to Arundel castle in Sussex, he was there taken prisoner by the parliamentary forces under the command of Sir William Waller, who obliged the castle to surrender. But his illness increasing, he obtained leave to be conveyed to Chichester, where he was lodged at the bishop's palace; and, after a short sickness, died in 1644. He hath left several excellent works behind him.

CHILMINAR. See PERSEPOLIS.

CHILO, one of the seven Æges of Greece, and of the ephori of Sparta the place of his birth, flourished about 556 years before Christ. He was accustomed to say, that there were three things very difficult: "To keep a secret; to know how best to employ our time; and to suffer injuries without murmuring." According to Pliny, it was he who caused the short sentence, *Know thyself*, to be written in letters of gold in the temple of Delphos. It is said that he died with joy, while embracing his son, who had been crowned at the Olympic games.

CHILOE, an island lying near the coast of Chili, in South America, under the 43^d degree of south latitude. It is the chief of an archipelago of 40 islands, and its principal town is Cañiro. It rains here almost all the year, inasmuch that nothing but Indian corn, or some such grain, that requires but little heat to ripen it, can ever come to perfection. They have excellent shell-fish, very good wild-fowl, hogs, sheep, and beeves. As also a great deal of honey and wax. They carry on a trade with Peru and Chili; whither they send boards of cedar, of which they have vast forests.

CHILTERN, a chain of chalky hills, running from east to west through Buckinghamshire.

CHIMÆRA, a port-town of Turkey in Europe, situated at the entrance of the gulph of Venice, in the province of Epirus, about 32 miles north of the city Corfu, near which are the mountains of Chimæra, which divide Epirus from Thessaly. E. Long. 20. 40. N. Lat. 40. 20.

CHIMÆRA, a fabulous monster, which the poets feign to have the head of a lion, the body of a goat, and the tail of a dragon; and add, that this odd beast was killed by Bellerophon. According to authors, the foundation of the fable was, that in Lycia there was a burning mountain or volcano of this name; that the top of this mountain was seldom without lions, nor the middle, which had very good grass, without goats; that serpents bred at the bottom, which was marshy; and that Bellerophon rendered the mountain habitable.

By a *chimera*, among the philosophers, is understood a mere creature of the imagination, composed of such contradictions and absurdities as cannot possibly any where exist but in thought.

CHIMES of a CLOCK, a kind of periodical music, produced at equal intervals of time, by means of a particular apparatus added to a clock.

In order to calculate numbers for the chimes, and adapt the chime-barrel, it must be observed, that the barrel must turn round in the same time that the tune it is to play requires in singing. As for the chime-barrel, it may be made up of certain bars that run athwart it, with a convenient number of holes punched in them to put in the pins that are to draw each hammer: and these pins, in order to play the time of the tune rightly, must stand upright, or hang down from the bar, some more, some less. To place the pins rightly, you may proceed by the way of changes on bells, viz. 1, 2, 3, 4; or rather make use of the musical notes. Observe what is the compass of your tune, and divide the barrel accordingly from end to end.

Thus in the examples on Plate LXXIX. fig. 1, 2, each of the tunes are eight notes in compass; and accordingly, the barrel is divided into eight parts. These divisions are struck round the barrel; opposite to which are the hammer-tails.

We speak here as if there were only one hammer to each bell, that it may be more clearly apprehended; but when two notes of the same found come together in a tune, there must be two hammers to the bell to strike it: so that if, in all the tunes you intend to chime of eight notes compass, there should happen to be such double notes on every bell; instead of eight, you must have sixteen hammers; and accordingly you must divide the barrel, and strike sixteen strokes round it, opposite to each hammer-tail: then you are to divide it round about, into as many divisions as there are musical bars, semibreves, minims, &c. in the tune.

Thus the hundredth-psalm tune has 20 semibreves, and each division of it is a semibreve: the first note of it also is a semibreve; and, therefore, on the chime-barrel must be a whole division, from five to five; as you may understand plainly, if you conceive the surface of a chime-barrel to be represented by the above figures, as if the cylindrical superficies of the barrel were stretched out at length, or extended on a plane: and then such a table, so divided, if it were to be wrapped round the barrel, would shew the places where all the pins are to stand in the barrel: for the dots running about the table, are the places of the pins that play the tune.

Indeed, if the chimes are to be complete, you ought to have a set of bells to the gamut notes; so as that, each bell having the true found of *sol, la, mi, fa*, you may play any tune with its flats and sharps: nay, you may by this means play both the bass and treble with one barrel: and by letting the names of your bells at the head of any tune, that tune may easily be transferred to the chime-barrel, without any skill in music: but it must be observed, that each line in the music is three notes distant; that is, there is a note between each line, as well as upon it.

CHIMNEY, in architecture, a particular part of a house, where the fire is made, having a tube or funnel to carry off the smoke.

Method of Building CHIMNEYS that will not smoke.

—Workmen have different methods of drawing up the funnels of chimneys, generally according to their own fancies and judgments, and sometimes according to the customs

Chimes.

China.

clustoms of places. They are seldom directed by sound and rational principles. It will be found for the most part, that the smoking of chimneys is owing to their being carried up narrower near the top than below, or, zig-zag, all in angles: in some cases, indeed, it is owing to accidental causes; but, for the most part, to those two above mentioned. Where they are carried up in the pyramid or tapering form, especially if the house be of a considerable height, it is ten to one but they sometimes smoke. The air in the rooms, being rarefied, is forced into the funnel of the chimney, and receives from the fire an additional force to carry up the smoke. Now it is evident, that the further up the smoke flies, the less is the force that drives it, the slower it must move, and consequently the more room in proportion it should have to move in; whereas in the usual way it has less, by the sides of the chimney being gathered closer and closer together.

The method here proposed of carrying up chimneys will be objected to by some thus: The wider a chimney is at the top, say they, the more liberty has the wind to blow down. Very true; but is it not resisted in going down, both by the form of the chimney and other evident causes, so that it must return again? In the other way, when the wind blows down, the resistance being less, the wind and smoke are, if we may use the expression, imprisoned, and make the smoke puff out below. This method has proved effectual after all others had failed; and that in a house placed in the worst situation possible, namely, under a high mountain to the southward, from which strong blasts blow down upon it. A vent was carried up without angles, as perpendicular as possible; and was made about three or four inches wider at top than at the bottom: the funnel was gathered in a throat directly above the fire-place, and so widening upwards. Since that time the house has not only ceased to smoke, but, when the doors stand open, the draught is so strong that it will carry a piece of paper out at the chimney-head. See more on this subject under the article SMOKE.

CHIMNEY-Money, otherwise called *Hearth-money*, a duty to the crown on houses. By stat. 14. Char. II. cap. 2. every fire-hearth, and stove of every dwelling or other house, within England and Wales (except such as pay not to church and poor), was chargeable with 2 s. per annum, payable at Michaelmas and Lady-day to the king and his heirs and successors, &c.; which payment was commonly called *chimney-money*. This tax, being much complained of as burthenome to the people, has been since taken off, and others imposed in its stead; among which that on windows has by some been esteemed almost equally grievous.

CHIMPANZEE, in natural history. See SIMIA.

Boundaries,
extent, &c.

CHINA, a country of Asia, situated on the most easterly part of that continent. It is bounded on the north by Tartary; from which it is divided, partly by a prodigious wall of 1500 miles in length, and partly by high, craggy, and inaccessible mountains. On the east, it is bounded by the ocean; on the west, by part of the Mogul's empire, and India beyond the Ganges, from which it is parted by other ridges of high moun-

tains and sandy deserts. On the south, it is bounded partly by the kingdoms of Lao, Tonquin, Ava, and Cochin-China, and partly by the southern or Indian sea, which flows between it and the Philippine islands. There are several ways of computing its length and breadth. According to some of these, it is reckoned 1269, 1600, or 1800 miles in length and as much in breadth: however, by the best and latest accounts, this vast country is somewhat of an oval form, the breadth being less than the length, by little more than a fourth-part. It contains 15 provinces, exclusive of that of *Lyau-tong*, which is situated without the great wall, though under the same dominion. Their names are, 1. Shenfi; 2. Shanfi; 3. Pecheli: which are situated on the north side, along the wall. 4. Shan-tong; 5. Kyan-nang; 6. Che-kyang; 7. Fo-kyen: which are situated along the eastern ocean. 8. Quang-tong; 9. Quang-li; 10. Yu-nan; 11. Se-chen: which stretch themselves towards the south and south-west. And, 12. Ho-nan; 13. Hu-quang; 14. Quey-chew; 15. Kyang-fi: which take up the middle part. For a particular description of all these, see their proper articles.

The origin of all nations is involved in obscurity and fable; but that of the Chinese much more so than any other. Every nation is inclined to assume too high an antiquity to itself, but the Chinese carry theirs beyond all bounds. Indeed, though no people on earth are more exact in keeping records of every memorable transaction, yet such is the genius of the Chinese for superstition and fable, that the first part of their history is deservedly condemned by every rational person. What contributes more to the uncertainty of the Chinese history is, that neither we, nor they themselves, have any thing but fragments of their ancient historical books; for about 213 years before Christ, the reigning emperor *Si-whang-ti* caused all the books in the empire to be burned, except those written by lawyers and physicians. Nay, the more effectually to destroy the memory of every thing contained in them, he commanded a great number of learned men to be buried alive, lest, from their memories, they should commit to writing something of the true memoirs of the empire. The inaccuracy of the Chinese annals is complained of even by their most respected author, Confucius himself; who also affirms, that, before his time, many of the oldest materials for writing such annals had been destroyed.

According to the Chinese historians, the first monarch of the whole universe, (that is, of China), was called *Poon-ku*, or *Puen-cu*. This, according to some, was the first man; but according to Bayer and Menzelius, two of the greatest critics in Chinese literature that have hitherto appeared, the word signifies the highest antiquity. *Poon-ku* was succeeded by *Tienc-hoang*, which signifies the emperor of heaven. They call him also the intelligent heaven, the supreme king of the middle heaven, &c. According to some of their historians, he was the inventor of letters, and of the Cyclic characters by which they determine the place of the year, &c. *Tienc-hoang* was succeeded by *Ti-hoang*, (the emperor of the earth), who divided the day and night, appointing 30 days to make one moon, and fixed the winter solstice to the 11th

moon. Ti-hoang was succeeded by Gine-hoang, (sovereign of men), who with his nine brothers shared the government among them. They built cities, and surrounded them with walls; made a distinction between the sovereign and subjects; instituted marriage, &c.

The reigns of these four emperors make up one of what the Chinese called *ki*, "ages," or "periods," of which there were nine before Fo-hi, whom their most sensible people acknowledge as the founder of their empire.

The history of the second *ki*, contradicts almost every thing said of the first; for though we have but just now been told that Gine-hoang and his brethren built cities surrounded with walls; yet, in the succeeding age, the people dwelt in caves, or perched upon trees as it were in nests. Of the third *ki* we hear nothing; and in the fourth, it seems matters had been still worse, as we are told that men were then only taught to retire into the hollows of rocks. Of the fifth and sixth we have no accounts. These six periods, according to some writers contained 90,000 years; according to others, 1,100,750.

In the seventh and eighth *ki*, they tell us over again what they had said of the first; namely, that men began to leave their caves and dwell in houses, and were taught to prepare clothes, &c. Tchine-kiang, the first monarch of the eighth *ki*, taught his subjects to take off the hair from skins with rollers of wood, and cover themselves with the skins so prepared. He taught them also to make a kind of web of their hair, to serve as a covering to their heads against rain. They obeyed his orders with joy, and he called his subjects *people clothed with skins*. His reign lasted 350 years; that of one of his successors, also, named Yeou-tiao-chi, lasted more than 300; and his family continued for 12 or 18,000 years. But what is very surprising, all these thousands and millions of years had elapsed without mankind having any knowledge of fire. This was not discovered till towards the close of this period, by one Souigine. After so useful a discovery, he taught the people to dress their vituals; whereas before, they had devoured the flesh of animals quite raw, drank their blood, and swallowed even their hair and feathers. He is also said to have been the inventor of fishing, letters, &c.

In the ninth period we find the invention, or at least the origin, of letters, attributed to one T'ang-hie, who received them from a divine tortoise that carried them on his shell, and delivered them into the hands of T'ang-hie. During this period also, music, money, carriages, merchandize and commerce, &c. were invented. There are various calculations of the length of these *ki* or periods. Some make the time from Puan-ku to Confucius, who flourished about 479 years before Christ, to contain 276,000 years; others, 2,276,000; some, 2,759,860 years; others, 3,276,000; and some no less than 96,961,740 years.

These extravagant accounts are by some thought to contain obscure and imperfect hints concerning the cosmogony, and creation of the world, &c. Puan-ku, the first emperor, they think represents eternity preceding the duration of the world. The succeeding ones, Tiene-hoang, Ti-hoang, and Gine-hoang, they

imagine, signify the creation of the heavens and earth, and the formation of man. The ten *ki*, or ages, nine of which preceded Fo-hi, mean the ten generations preceding Noah. This may very possibly be the case; for about 300 years before Christ, some Jews travelled into China, who might have made the Mosaic writings known there.

What we have now related, contains the substance of that part of the Chinese history which is entirely fabulous. After the nine *ki* or "ages" already taken notice of, the tenth commenced with Fo-hi; and the history, though still very dark, obscure, and fabulous, begins to grow somewhat more consistent and intelligible. Fo-hi was born in the province of Shenfi. His mother walking upon the bank of a lake in that province, saw a very large print of a man's foot in the sand there; and, being surrounded by an iris or rainbow, became impregnated. The child was named *Fo-hi*; and, when he grew up, was by his countrymen elected king on account of his superior merit, and styled *T'ient-tse*, that is "the son of heaven." He invented the eight *qua*, or symbols, consisting of three lines each, which, differently combined, formed 64 characters that were made use of to express every thing. To give these the greater credit, he pretended that he had seen them inscribed on the back of a dragon-horse, (an animal shaped like a horse, with the wings and scales of a dragon), which arose from the bottom of a lake. Having gained great reputation among his countrymen for this prodigy, he is said to have created mandarins or officers, under the name of *dragons*. Hence we may assign a reason why the emperors of China always carry a dragon in their banners. He also instituted marriage, invented music, &c. Having established a prime minister, he divided the government of his dominions among four mandarins, and died after a reign of 115 years.

After Fo-hi followed a succession of emperors, of whom nothing remarkable is recorded, except that in the reign of *Tau*, the seventh after Fo-hi, the sun did not set for 10 days, so that the Chinese were afraid of a general conflagration. This event the compilers of the Universal history take to be the same with that mentioned in the book of Joshua, when the sun and moon stood still for about the space of a day. Fo-hi, they will have to be the same with Noah. They imagine, that after the deluge, this patriarch remained some time with his descendants; but on their wicked combination to build the tower of Babel, he separated himself from them with as many as he could persuade to go along with him; and that, still travelling eastward, he at last entered the fertile country of China, and laid the foundation of that vast empire.—But, leaving these fabulous and conjectural times, we shall proceed to give some account of that part of the Chinese history, which may be more certainly depended on.

As the Chinese, contrary to the practice of almost all nations, have never sought to conquer other countries, but rather to improve and content themselves with their own, their history for many ages furnishes nothing remarkable. The whole of their emperors, abstracting from those who are said to have reigned in the fabulous times, are comprehended

20. <i>Iwen</i> ,	8	1280.
21. <i>Ming</i> ,	16	1368.
22. <i>Tsing</i> ,		1645.

This table is formed according to the accounts of the Jesuit Du Halde, and is commonly reckoned to be the most authentic; but according to the above mentioned hypothesis of the compilers of the Universal History, who make *Yau* cotemporary with Joshua, the dynasty of *Hya* did not commence till the year before Christ 1357; and to accommodate the history to their hypothesis, great alterations must be made in the duration of the dynasties.

The most interesting particulars of the Chinese history relate only to the incursions of the Tartars, who at last conquered the whole empire, and who still continue to hold the sovereignty; though by transferring the seat of the empire to Peking, and adopting the Chinese language, manners, &c. Tartary would seem rather to have been conquered by China, than China by Tartary. These incursions are said to have begun very early; even in the time of the emperor *Shun*, successor to *Yau* above mentioned, in whose reign the miraculous solstice happened. At this time, however, the Tartars were repulsed, and obliged to retire into their own territories. From time to time, however, they continued to threaten the empire with invasions, and the northern provinces were often actually ravaged by the Tartars in the neighbourhood. About the year before Christ 213, *Shi-whang-ti*, having fully subdued all the princes, or *kingi*, as they were called, of the different provinces, became emperor of China with unlimited power. He divided the whole empire into 36 provinces; and finding the northern part of his dominions much incommoded by the invasions of the neighbouring barbarians, he sent a formidable army against them which drove them far beyond the boundaries of China. To prevent their return, he built the famous wall already mentioned, which separates China from Tartary. After this, being elated with his own exploits, he formed a

design of making posterity believe that he himself had been the first Chinese emperor that ever sat on the throne. For this purpose, he ordered all the historical writings to be burnt, and caused many of the learned to be put to death, as already mentioned.

What effect the great wall for some time had in preventing the invasions of the Tartars, we are not told; but in the tenth century of the Christian era, those of *Kitan* or *Lyau* got a footing in China. The *Kitan* were a people of Eastern Tartary, who dwelt to the north and north-east of the province of *Pecheli* in China, particularly in that of *Layu-tong* lying without the great wall. These people having subdued the country between *Korea* and *Kalgai*, became much more troublesome to the Chinese than all the other Tartars. Their empire commenced about the year 916, in the fourth year of *Mo-ti-kyun-ti*, second emperor of the 14th Chinese dynasty called *Hew-lyang*. In 946, *Ming-ti*, second emperor of the 15th dynasty, being dead, *Sheking-tang*, his son-in-law, rebelled against *Ming-ti*, his son and successor, whom he deprived of his crown and life. This he accomplished by means of an army of 50,000 men furnished by the *Kitan*. *Fi-ti*, the son of *Ming-ti*, being unable to resist the usurper, fled to the city *Ghey-chew*; where shutting himself up with his family and all his valuable effects, he set fire to the palace and was burnt to ashes. On his death, *Sheking-tang* assumed the title of emperor; founded the 16th dynasty; and changed his name to that of *Kaut-su*. But the *Kitan* general refusing to acknowledge him, he was obliged to purchase a peace by yielding up to the Tartars 16 cities in the province of *Pecheli*, besides a yearly present of 300,000 pieces of silk.

This submission served only to enflame the avarice and ambition of the *Kitan*. In 959, they broke the treaty when least expected, and invaded the empire afresh. *Tsi-vang*, the emperor at that time, opposed them with a formidable army; but through the treachery of his general *Lyew-chi-ywen*, the Tartars were allowed to take him prisoner. On this, *Tsi-vang* was glad to recover his liberty by accepting of a small principality; while the traitor became emperor of all China, and changing his name to *Kaut-su*, founded the 17th dynasty. The Tartars, in the mean time, ravaged all the northern provinces without opposition, and then marched into the southern. But being here stopped by some bodies of Chinese troops, the general thought proper to retire with his booty into Tartary. In 962, *Kaut-li*, dying, was succeeded by his son *Li-ti*. The youth of this prince gave an opportunity to the eunuchs to raise commotions; especially as the army was employed at a distance in repelling the invasions of the Tartars. This army was commanded by *Ko-ghey*, who defeated the enemy in several battles, and thus restored peace to the northern provinces. In the mean time, *Li-ti* was slain by his eunuchs, and the empress placed his brother on the throne: but *Ko-ghey*, returning in triumph, was saluted emperor by his victorious army, and the empress being unable to support the rights of her son, was obliged to submit, while *Ko-ghey*, assuming the name of *Yay-tsu*, founded the 18th dynasty. Nine years after

after this, however, the grandees of the empire, setting aside Kong-ti, the third in succession from Tay-tsu, on account of his non-age, proclaimed his guardian, named *Chau-quang-yu*, emperor; who, assuming the name of Kau-tsu, founded the 19th dynasty, called *Song*, or *Tsong*.

Under this monarch the empire began to recover itself; but the Kitan still continued their incursions. The successors of Kau-tsu opposed them with various success; but at last, in 978, the barbarians became so strong as to lay siege to a considerable city. Tay-tsong, successor to Kau-tsu, detached 200 soldiers, each carrying a light in his hand, against them in the night-time, with orders to approach as near as possible to the Tartar camp. The barbarians, imagining, by the number of lights, that the whole Chinese army was at hand, immediately fled, and, falling into the ambuscades laid for them by the Chinese general, were almost all cut to pieces.

This check, however, did not long put a stop to the ravages of the Kitan. In the year 999, they laid siege to a city in the province of Pecheli; but Ching-tsong, successor to Tay-tsong, came upon them with his army so suddenly, that they took themselves to flight. The emperor was advised to take advantage of their consternation, and recover the country which had been yielded to them; but instead of pursuing his victory, he bought a peace, by consenting to pay annually 100,000 taels (about L. 34,000), and 200,000 pieces of silk. The youth and pacific disposition of Jin-tsong, successor to Ching-tsong, revived the courage of the Kitan; and, in 1035, war would have been renewed, had not the emperor condescended to as shameful a treaty as that concluded by his father. Two years after, the Tartars demanded restitution of ten cities in the province of Pecheli, which had been taken by Ko-giely founder of the 18th dynasty; upon which Jin-tsong engaged to pay them an annual tribute of 200,000 taels of silvers, and 300,000 pieces of silk in lieu of these cities.

From this time, the Kitan remained in peaceable possession of their Chinese dominions till the year 1117. Whey-tsong, at that time emperor, being able neither to bear their ravages, nor by himself to put a stop to them, resolved upon a remedy which at last proved worse than the disease. This was to call in the Nu-che, Nyu-che, or Eastern Tartars, to destroy the kingdom of the Kitan. From this he was dissuaded by the king of Korea, and most of his own ministers; but, disregarding their salutary advice, he joined his forces to those of the Nu-che. The Kitan were then every where defeated; and at last reduced to such extremity, that those who remained were forced to leave their country, and fly to the mountains of the west.

Thus the empire of the Kitan was totally destroyed, but nothing to the advantage of the Chinese; for the Tartar general, elated with his conquest, gave the name of *Kin* to his new dominion, assumed the title of emperor, and began to think of aggrandizing himself and enlarging his empire. For this purpose, he immediately broke the treaties concluded with the Chinese emperor; and, invading the provinces of Pecheli and Shen-si, made himself master of the greater

part of them. Whey-tsong, finding himself in danger of losing his dominions, made several advantageous proposals to the Tartar; who, seeming to comply with them, invited him to come and settle matters by a personal conference. The Chinese monarch complied; but, on his return, the terms agreed on seemed intolerable to his ministers; so that they told him the treaty could not subsist, and that the most cruel war was preferable to such an ignominious peace. The Kin monarch, being informed of all that passed, had recourse to arms, and took several cities. Whey-tsong was weak enough to go in person to hold a second conference; but, on his arrival, was immediately seized by the Tartar. He was kept prisoner under a strong guard during the remaining part of his life; and ended his days in 1126, in the desert of Shamo, having nominated his eldest son Kin-tsong to succeed him.

Kin-tsong began his reign with putting to death six ministers of state, who had betrayed his father into the hands of the Kin Tartars. The barbarians in the mean time pursued their conquests without opposition. They crossed the Whang-ho, or Yellow River, which an handful of troops might have prevented; and marching directly towards the imperial city, took and plundered it. Then seizing the emperor and his consort, they carried them away captives; but many of the principal lords, and several of the ministers, preferring death to such an ignominious bondage, killed themselves. The Kin being informed by the empress *Meng* that he had been divorced, they left her behind. This proved the means of saving the empire; for by her wisdom and prudence she got the crown placed on the head of Kau-tsong, ninth son of the emperor Whey-tsong by his divorced empress.

Kau-tsong fixed his court at Nanking the capital of Kyang-nan; but soon after was obliged to remove it to Kang-chew in Che-kyang. He made several efforts to recover some of his provinces from the Kin, but without effect. Ili-tsong the Kin monarch, in the mean time, endeavoured to gain the esteem of his Chinese subjects by paying a regard to their learning and learned men, and honouring the memory of Confucius. Some time after, he advanced to Nanking, from whence Kau-tsong had retired, and took it; but, receiving advice that Yo-si, general of the Song, or southern Chinese, was advancing by long marches to the relief of that city, they set fire to the palace, and retired northward. However, Yo-si arrived time enough to fall upon their rear-guard, which suffered very much; and from this time the Kin never dared to cross the river Yangtze. In a few years afterwards the Chinese emperor submitted to become tributary to the Kin, and concluded a peace with them upon very dishonourable terms. This submission, however, was of little avail: for, in 1163, the Tartars broke the peace; and, invading the southern province with a formidable army, took the city of Yang-chew. The king, having approached the river Yangtze, near its mouth, where it is widest as well as most rapid, commanded his troops to cross it, threatening with his drawn sword to kill those who refused. On receiving such an unreasonable command, the whole army mutinied; and the king being killed in the beginning

gining of the tumult, the army immediately retired.

From this time to the year 1210, nothing remarkable occurs in the Chinese history; but this year, Jenghiz-khan, chief of the western Tartars, *Moguls*, or *Mungli*, quarrelled with Yong-tsi emperor of the Kin; and at the same time the king of Hya, disgusted at being refused assistance against Jenghiz-khan, threatened him with an invasion on the west-side. Yong-tsi prepared for his defence; but in 1211, receiving news that Jenghiz-khan was advancing southward with his whole army, he was seized with fear, and made proposals of peace, which were rejected. In 1212, the Mogul generals forced the great wall; or, according to some writers, had one of the gates treacherously opened to them, to the north of Shan-ti; and made incursions as far as Peking the capital of the Kin empire. At the same time the province of Lyan-tong was almost totally reduced by several Kitan lords who had joined Jenghiz-khan; several strong places were taken, and an army of 300,000 Kin defeated by the Moguls. In autumn they laid siege to the city of Tay-tong-fu; where, although the governor Hujaku fled, yet Jenghiz-khan met with considerable resistance. Having lost a vast number of men; and being himself wounded by an arrow, he was obliged to raise the siege and retire into Tartary; after which the Kin retook several cities. The next year, however, Jenghiz-khan re-entered China; retook the cities which the Kin had reduced the year before; and overthrew their armies in two bloody battles, in one of which the ground was strewn with dead bodies for upwards of four leagues.

The same year Yong-tsi was slain by his general Hujaku; and Sun, a prince of the blood, advanced in his room. After this the Moguls, attacking the empire with four armies at once, laid waste the provinces of Shan-ti, Honan, Pecheli, and Shantung. In 1214 Jenghiz-khan sat down before Peking; but instead of assaulting the city, offered terms of peace, which were accepted, and the Moguls retired into Tartary. After their departure, the emperor, leaving his son at Peking, removed his court to Pien-lyang near Kay-fong-fu, the capital of Honan. At this Jenghiz-khan being offended, immediately sent troops to besiege Peking. The city held out to the fifth month of the year 1215, and then surrendered. At the same time the Moguls finished the conquest of Lyan-tong; and the Song refused to pay the usual tribute to the Kin.

In 1216, Jenghiz-khan returned to pursue his conquests in the west of Asia, where he fluid seven years; during which time his general Muhli made great progress in China against the Kin emperor. He was greatly assisted by the motions of Ning-tsong emperor of the Song, or southern China; who, incited by the frequent perfidies of the Kin, had declared war against them, and would hearken to no terms of peace, though very advantageous proposals were made. Notwithstanding this, however, in 1220, the Kin, exerting themselves, raised two great armies, one in Shen-ti, and the other in Shang-tong. The former baffled the attempts of the Song and king of Hya, who had united against them; but the latter, though no fewer than 200,000, were entirely defeated by Muhli. In 1221,

that officer passed the Whang-ho, and died after conquering several cities.

In 1224, the Kin emperor died; and was succeeded by his son Shew, who made peace with the king of Hya: but next year, that kingdom was entirely destroyed by Jenghiz-khan. In 1226, Oktay son to Jenghiz-khan marched into Honan, and besieged Kay-Song-fu, capital of the Kin empire; but was obliged to withdraw into Shen-ti, where he took several cities, and cut in pieces an army of 30,000 men. In 1227 Jenghiz-khan died, after having desired his sons to demand a passage for their army through the dominions of the Song, without which he said they could not easily vanquish the Kin.

After the death of that great conqueror, the war was carried on with various success; but though the Moguls took above 60 important posts in the province of Shen-ti, they found it impossible to force Tong-quan, which it behoved them to do in order to penetrate effectually into Honan. In April 1231 they took the capital of Shen-ti, and defeated the Kin army which came to its relief. Hereupon Toley, having assembled all his forces, sent a messenger to the Song generals to demand a passage through their territories. This, however, they not only refused, but put the messenger to death; which so enraged Toley that he swore to make them repent of it, and was soon as good as his word. He decamped in August 1231; and having forced the passages, put to the sword the inhabitants of

Wha-yang and Pong-chew, two cities in the district of Han-chong-fu. Then having cut down rocks to fill up deep abysses, and made roads through places almost inaccessible, he came and besieged the city of Han-chong-fu itself. The miserable inhabitants fled to the mountains on his approach, and more than 100,000 of them perished. After this, Toley divided his forces, consisting of 30,000 horse, into two bodies. One of these went westward to Myen-chew: from thence, after opening the passages of the mountains, they arrived at the river Kyaling, which runs into the great Kyang. This they crossed on rafts made of the wood of demolished houses; and then, marching along its banks, seized many important posts. At last, having destroyed more than 140 cities, towns, or fortresses, they returned to the army. The second detachment seized an important post in the mountains, called *Tantong*, six or seven leagues to the eastward of Han-chong-fu. On the other side Oktay advanced, in October, towards Pu-chew a city of Shan-ti; which being taken after a vigorous defence, he prepared to pass the Whang-ho. Toley, after surmounting incredible difficulties, arrived in December on the borders of Honan, and made a shew as if he designed to attack the capital of the Kin empire. On his first appearance in Honan through a passage so little suspected, every body was filled with terror and astonishment, so that he proceeded for some time without opposition. At last the emperor ordered his generals, Hota, Ilapua, and others, to march against the enemy.

Tolcy boldly attacked them; but was obliged to retire, which he did in good order. Hota was for pursuing him, saying that the Mogul army did not exceed 30,000 men, and that they seemed not to have eaten any thing for two or three days. Ilapua, however, was of opinion that there was no occasion for being so hasty, as the Moguls were inclosed between the rivers Han and Whang-ho, so that they could not escape. This negligence they soon had occasion to repent of: for Tolcy, by a stratagem, made himself master of their heavy baggage; which accident obliged them to retire to Tang-chew. From thence they sent a messenger to acquaint the emperor that they had gained the battle, but concealed the loss of their baggage. This good news filled the court with joy; and the people who had retired into the capital for its defence, left it again, and went into the country; but, in a few days after, the vanguard of the Moguls, who had been sent by the emperor Oktay, appeared in the field, and carried off a great number of those that had quitted the city.

25
Capital of
the Kin em-
pire besieged.

In January 1232, Oktay passing the Whang-ho; encamped in the district of Kay-fong-fu, capital of the Kin empire, and sent his general Suputay to besiege the city. At that time the place was near 30 miles in circumference: but having only 40,000 soldiers to defend it, as many more from the neighbouring cities, and 20,000 peasants, were ordered into it; while the emperor published an affecting declaration, animating the people to defend it to the last extremity. Oktay, having heard with joy of Tolcy's entrance into Honan, ordered him to send succours to Suputay. On the other hand, the Kin generals advanced with 150,000 men to relieve the city; but being obliged to divide their forces in order to avoid in part the great road which Tolcy had obstructed with trees, they were attacked by that prince at a disadvantage, and, after a faint resistance, defeated with great slaughter, and the loss of both their generals, one killed and the other taken. The emperor now ordered the army at Tong-quan and other fortified places, to march to the relief of Kay-fong-fu. They assembled accordingly, to the number of 110,000 foot and 15,000 horse; and were followed by vast numbers of people who expected by their means to be protected from the enemy. But many of those troops having deserted, and the rest being enfeebled by the fatigues of their march, they dispersed on the approach of their pursuers, who killed all they found in the highways. After this the Moguls took Tong-quan and some other considerable posts; but were obliged to raise the sieges of Quey-te-fu and Loyang, by the bravery of the governors. Kyang-shin, governor of Loyang, had only 3 or 4000 soldiers under him, while his enemies were 30,000 strong. He placed his worst soldiers on the walls, putting himself at the head of 400 brave men; whom he ordered to go naked, and whom he led to all dangerous attacks. He invented engines to cast large stones, which required but few hands to play them, and aimed so true as to hit at 100 paces distance. When their arrows failed, he cut those shot by the enemy into four pieces; pointed them with pieces of brass coin; and discharged them from wooden tubes with as much force as bullets are from a musket.

Thus he harrassed the Moguls for three months so grievously, that they were obliged, notwithstanding their numbers, to abandon the enterprise.

Oktay, at last, notwithstanding his successes, resolved to return to Tartary; and offered the Kin emperor peace, provided he became tributary, and delivered up to him 27 families which he named. These offers were very agreeable to the emperor; but Suputay, taking no notice of the treaty, pushed on the siege of the capital with more vigour than ever. By the help of the Chinese slaves in his army, the Mogul general soon filled the ditch; but all his efforts seemed only to inspire the besieged with new vigour. The Moguls at that time made use of artillery, but were unable to make the least impression upon the city walls. They raised walls round those they besieged, which they fortified with ditches, towers, and battlements. They proceeded also to sap the walls of the city; but were very much annoyed by the artillery of the besieged, especially by their bombs, which sinking into the galleries, and bursting under ground, made great havoc among the miners. For 16 days and nights the attacks continued without intermission; during which time an incredible number of men perished on both sides: at length, Suputay, finding that he could not take the city, withdrew his troops, under pretence of conferences being on foot. Soon after, the plague cluded; began in Kay-fong-fu; and raged with such violence, that, in 50 days, 900,000 biers were carried out, besides a vast multitude of the poorer sort who could not afford any.

In a short time, two unlucky accidents occasioned a renewal of the war; which now put an end to the empire of the Kin. Gan-yong, a young Mogul lord, having assumed the government of some cities in Kyang-nan, and killed the officer sent to take possession of them, declared for the Kin. The emperor unwarily took Gan-yong into his service, and gave him the title of Prince. Upon this Oktay sent an envoy, attended by 30 other persons, to inquire into the affair; but the Kin officers killed them all, without being punished by the emperor. Suputay, having informed his master of all these proceedings, was ordered to continue the war in Honan. Shew-fu now commanded his officers to unite their troops for the defence of the capital; but before his orders could be obeyed, they were attacked and defeated, one after another, by the Moguls. This obliged him to raise soldiers from among the peasants, for whose subsistence the people were taxed $\frac{1}{3}$ of the rice they possessed. The city began now to be distressed for want of provisions; and as it was but in a bad posture of defence, the emperor marched with an army against the Moguls. His expedition proved unfortunate; for, sending part of his army to besiege a city called Why-chew, it was totally cut in pieces, and Suputay a second time sat down before the capital.

On hearing this bad news, the emperor repassed the Whang-ho, and retired to Quey-te-fu. Here he had not been long, before the capital was delivered up by treachery, and Suputay put all the males of the imperial race to death; but, by the express command of Oktay, spared the inhabitants, who are said to have amounted to 1,430,000 families. After this disaster the

China. the unhappy monarch left his troops at Quey-te-fu, and retired to Juning-fu, a city in the southern part of Honan, attended only by 400 persons. Here the diffidence of the Moguls made him think of living at ease; but while he flattered himself with these vain hopes, the enemy's army arrived before the city and invested it. The garrison were terrified at their approach; but were encouraged by the emperor, and his brave general Hu-fye-hu, to hold out to the last. As there were not in the city a sufficient number of men, the women, dressed in men's clothes, were employed to carry wood, stones, and other necessary materials to the walls. All their efforts, however, were ineffectual. They were reduced to such extremities, that for three months they fed on human flesh; killing the old and feeble, as well as many prisoners, for food. This being known to the Moguls, they made a general assault in January 1234. The attack continued from morning till night; but at last the assailants were repulsed. In this action, however, the Kin lost all their best officers; upon which the emperor resigned the crown to Cheng-lin a prince of the blood. Next morning, while the ceremony of investing the new emperor was performing, the enemy mounted the south walls, which were defended only by 200 men; and the south gate being at the same time abandoned, the whole army broke in. They were opposed, however, by Hu-fye-hu; who, with 1000 soldiers, continued to fight with amazing intrepidity. In the mean time Shew-fu, seeing every thing irreparably lost, lodged the seal of the empire in a house; and then causing sheaves of straw to be set round it, ordered it to be set on fire as soon as he was dead. After giving this order he hanged himself, and his commands were executed by his domestics. Hu-fye-hu, who still continued fighting with great bravery, no sooner heard of the tragical death of the emperor, than he drowned himself in the river Ju; as did also 500 of his most resolute soldiers. The same day the new emperor, Cheng-lin, was slain in a tumult; and thus an end was put to the dominion of the Kin Tartars in China.

The empire of China was now to be shared between the Song, or southern Chinese, and the Moguls. It had been agreed upon, that the province of Honan should be delivered up to the Song as soon as the war was finished. But they, without waiting for the expiration of the term, or giving Oktay notice of their proceedings, introduced their troops into Kay-fong-fu, Lo-yang, and other considerable cities. On this the Mogul general resolved to attack them; and re-passing the Whang-ho, cut in pieces part of the garrison of Lo-yang, while they were out in search of provisions. The garrison of Kay-fong-fu likewise abandoned that place; and the Song emperor degraded the officers who had been guilty of those irregularities, sending ambassadors to Oktay, at the same time, to desire a continuance of the peace. What Oktay's answer was we are not told, but the event shewed that he was not well pleased; for, in 1235, he ordered his second son Prince Kotovan, and his general Chahay, to attack the Song in Se-chwen, while others marched towards the borders of Kyang-nan.

In 1236, the Moguls made great progress in the province of Huquang, where they took several cities, Vol. III.

and put vast numbers to the sword. This year they introduced paper or silk money, which had formerly been used by Chang-t'ong, sixth emperor of the Kin. Prince Kotovan forced the passages into the district of Han-chong-fu in the province of Shenfi, which he entered with an army of 500,000 men. Here a terrible battle was fought between the vast army of the Moguls and the Chinese troops, who had been driven from the passages they defended. The latter consisted only of 10,000 horse and foot, who were almost entirely cut off; and the Moguls lost such a number of men, that the blood is said to have run for two leagues together. After this victory the Moguls entered Se-chwen, which they almost entirely reduced, committing such barbarities, that, in one city, 40,000 people chose rather to put an end to their own lives than submit to such cruel conquerors.

In 1237, the Moguls received a considerable check before the city of Kantong in Kyang-nan, the siege of which they were obliged to raise with loss. In 1238 they besieged Lu-chew, another city in the same province. They surrounded it with a rampart of earth and a double ditch; but the Chinese general ordered their intrenchments to be filled with immense quantities of herbs steeped in oil, and then set on fire; while he shot stones upon them from a tower seven stories high. At the same time a vigorous sally was made; and the Mogul army being thrown into the utmost disorder, were obliged finally to abandon the siege, and retire northwards.

In 1239, these barbarians were opposed by a general called Meng-kong, with great success; who this and the following year, gained great honour by his exploits. While he lived, the Moguls were never able to make any considerable progress; but his death, in 1246, proved of the greatest detriment to the Chinese affairs; and soon after, the Tartars renewed the war with more vigour and success than ever. In 1255, they re-entered the province of Se-chwen; but still met with vigorous opposition in this quarter, because the Chinese took care to have Se-chwen furnished with good troops and generals. Though they were always beaten, being greatly inferior in number to their enemies, yet they generally retook the cities the Moguls had reduced, as the latter were commonly obliged to withdraw for want of provisions and forage. In 1259 they undertook the siege of Ho-chew, a strong city to the west of Peking, defended by Vang-kyen, a very able officer, who commanded a numerous garrison. The siege continued from the month of February till August, during which time the Moguls lost an immense number of men. On the 10th of August they made a general assault in the night. They mounted the walls before the governor had intelligence; but were soon attacked by him with the utmost fury. The Mogul emperor, Meng-ko, himself came to the scalade; but his presence was not sufficient to overcome the valour of Vang-kyen. At the same time the scaling-ladders of the Moguls were blown down by a storm; upon which a terrible slaughter ensued, and among the rest fell the emperor himself. Upon this disaster the Mogul generals agreed to raise the siege, and retire towards Shen-fi.

who succeeded him, laid siege to Vu-chang-fu, a city not far distant from the capital of the Song empire. At this the emperor being greatly alarmed, distributed immense sums among his troops; and having caused great levies to be made throughout the empire, sent a formidable army to the relief of Vu-chang-fu. Unfortunately the command of this army was committed to the care of Kya-tse-tau, a man without either courage or experience in war. He was besides very vain and vindictive in his temper; often using the best officers ill, and entirely overlooking their merit, which caused many of them to go over to the Moguls. The siege of Vu-chang-fu was commenced, and had continued a considerable time, when Kya-tse-tau, afraid of its being lost, and at the same time not daring to take any effectual step for its relief, made proposals of peace. A treaty was accordingly concluded, by which Kya-tse-tau engaged to pay an annual tribute of about L. 50,000 in silver; and as much in silk; acknowledging likewise the sovereignty of the Moguls over the Song empire. In consequence of this treaty, the Moguls retreated after the boundaries of the two empires had been fixed, and repassed the Kyang; but 170 of them having flaid on the other side of the river, were put to death by Kya-tse-tau.

37
Treachery
of a Chi-
nese mini-
ster.

This wicked minister totally concealed from the emperor his having made such a shameful treaty with the Moguls; and the 170 foldiers massacred by his order, gave occasion to a report that the enemy had been defeated; so that the Song court believed that they had been compelled to retreat by the superior valour and wisdom of Kya-tse-tau. This proved the ruin of the empire; for, in 1260, the Mogul emperor sent Haukung to the Chinese court to execute the treaty according to the terms agreed on with Kya-tse-tau. The minister, dreading the arrival of this envoy, imprisoned him near Nanking; and took all possible care that neither Hupilay, nor Li-tsong the Chinese emperor, should ever hear any thing of him.

It was impossible such unparalleled conduct could fail to produce a new war. Hupilay's courtiers incessantly pressed him to revenge himself on the Song for their treacherous behaviour; and he soon published a manifesto against them, which was followed by a renewal of hostilities in 1268. The Mogul army amounted to 500,000 men; but notwithstanding their numbers, little progress was made till the year 1271. Syan-yang and Fan-ching, cities in the province of Se-chew, had been besieged for a long time ineffectually; but this year an *Igar* lord advised Hupilay to send for several of those engineers out of the west, who knew how to cast stones of 150 pounds weight out of their engines, which made holes of seven or eight feet wide in the strongest walls. Two of these engineers were accordingly sent for; and after giving a specimen of their art before Hupilay, were sent to the army in 1272. In the beginning of 1273 they planted their engines against the city of Fan-ching, and presently made a breach in the walls. After a bloody conflict the suburbs were taken; and soon after the Moguls made themselves masters of the walls and gates of the city. Nevertheless a Chinese officer, with only 100 soldiers, refused to fight from street to street. This he did for a long time with the greatest obstinacy,

38
Desperate
conflict.

killing vast numbers of the Moguls; and both parties are said to have been so much overcome with thirst, that they drank human blood to quench it. The Chinese set fire to the houses, that the great beams, falling down, might embarrass the way of their pursuers; but at last being quite wearied out, and filled with despair, they put an end to their own lives. After the taking of Fan-ching, all the materials which had served at the siege were transported to Syen-yang. The two engineers posted themselves against a wooden retrenchment raised on the ramparts. This they quickly demolished; and the besieged were so intimidated by the noise and havoc made by the stones cast from these terrible engines, that they immediately surrendered.

In 1274 Pe-yen, an officer of great valour, and endowed with many other good qualities, was promoted to the command of the Mogul army. His first exploits were the taking of two strong cities; after which he passed the great river Ky-ang, defeated the Song army, and laid siege to Vu-chang-fu. This city was soon intimidated into a surrender; and Pe-yen, by restraining the barbarity of his soldiers, whom he would not allow to hurt any body, soon gained the hearts of the Chinese so much, that several cities surrendered to him on the first summons. In the mean time the treacherous Kya-tse-tau, who was sent to oppose Pe-yen, was not ashamed to propose peace on the terms he had formerly concluded with Hupilay; but these being rejected, he was obliged at length to come to an engagement. In this he was defeated, and Pe-yen continued his conquests with great rapidity. Having taken the city of Nanking, and some others, he marched towards Hang-chew-fu, the capital of the Song empire. Peace was now again proposed, but rejected by the Mogul general; and at last the empress was constrained to put herself, with her son, then an infant, into the hands of Pe-yen, who immediately sent them to Hupilay.

39
Chinese
Empress
submits.

The submission of the empress did not yet put an end to the war. Many of the chief officers swore to do their utmost to rescue her from the hands of her enemies. In consequence of this resolution they distributed their money among the soldiers, and soon got together an army of 40,000 men. This army attacked the city where the young emperor Kongsong was lodged, but without success; after which, and several other vain attempts, they raised one of his brothers to the throne, who then took upon him the name of Twon-tsong. He was but nine years of age when he was raised to the imperial dignity, and enjoyed it but a very short time. In 1277 he was in great danger of perishing, by reason of the ship on board which he then was being cast away. The poor prince fell into the water, and was taken up half dead with the fight. A great part of his troops perished at that time, and he soon after made offers of submission to Hupilay. These, however, were not accepted; for, in 1278, the unhappy Twon-tsong was obliged to retire into a little desert island on the coast of Quang-tong, where he died in the 11th year of his age.

Notwithstanding the progress of the Moguls, vast territories still remained to be subdued before they could

40
Dissolution
of the Song
empire.

China.

could become masters of all the Chinese empire. On the death of T'won-t'ong, therefore, the mandarins raised to the throne his brother, named Te-ping, at that time but eight years of age. His army consisted of no fewer than 200,000 men; but being utterly void of discipline, and entirely ignorant of the art of war, they were defeated by 20,000 Mogul troops. Nor was the fleet more successful; for being put in confusion by that of the Moguls, and the emperor in danger of falling into their hands, one of the officers taking him on his shoulders, jumped with him into the sea, where they were both drowned. Most of the mandarins followed this example, as did also the empress and minister, all the ladies and maids of honour, and multitudes of others, inasmuch that 100,000 people are thought to have perished on that day. Thus ended the Chinese race of emperors; and the Mogul dynasty, known by the name of *Yuen*, commenced.

47
Reign of
Hupilay.

Though no race of men that ever existed were more remarkable for cruelty and barbarity than the Moguls; yet it doth not appear, that the emperors of the *Yuen* dynasty were in any respect worse than their predecessors. On the contrary, Hupilay, by the Chinese called *Shi-tu*, found the way of reconciling the people to his government, and even of endearing himself to them so much, that the reign of his family is to this day styled by the Chinese *the wise government*. This he accomplished by keeping as close as possible to their ancient laws and customs; by his mild and just government; and by his regard for their learned men. He was indeed ashamed of the ignorance and barbarity of his Mogul subjects, when compared with the Chinese. The whole knowledge of the former was summed up in their skill in managing their arms and horses, being perfectly destitute of every art or science, or even of the knowledge of letters. In 1269, he had caused the Mogul characters to be contrived. In 1280, he caused some mathematicians search for the source of the river Whang-ho, which at that time was unknown to the Chinese themselves. In four months time they arrived in the country where it rises, and made a map of it, which they presented to his majesty. The same year a treatise on astronomy was published by his order; and, in 1282, he ordered the learned men to repair from all parts of the empire to examine the state of literature, and take measures for its advancement.

At his first accession to the crown he fixed his residence at Tay-ywen-fu, the capital of Shen-si; but thought proper afterwards to remove it to Peking. Here, being informed that the barks which brought to court the tribute of the southern provinces, or carried on the trade of the empire, were obliged to come by sea, and often suffered shipwreck, he caused that celebrated canal to be made, which is at present one of the wonders of the Chinese empire, being 300 leagues in length. By this canal above 9000 imperial barks transport with ease, and at small expence, the tribute of grain, rice, silks, &c. which is annually paid to the court. In the third year of his reign Shi-tu formed a design of reducing the islands of Japan, and the kingdoms of Tonkin and Cochinchina. Both these enterprizes ended unfortunately, but the first remarkably so; for of 100,000 persons employed in

it, only four or five escaped with the melancholy news of the destruction of the rest, who all perished by shipwreck. Shi-tu reigned 15 years, died in the 80th year of his age, and was succeeded by his grandson. The throne continued in the *Yuen* family till the year 1367, when Shun-ti the last of that dynasty was driven out by a Chinese named Chu. During this period the Tartars had become enervated by long prosperity; and the Chinese had been roused into valour by their subjection. Shun-ti, the reigning prince, was quite sunk in sloth and debauchery; and the empire, besides, was oppressed by a wicked minister named Ama. In June 1355, Chu, a Chinese of mean extraction, and head of a small party, set out from Ho-chew, passed the Kyang, and took Tay-ping. He then associated himself with some other malcontents, at the head of whom he reduced the city of Ta-chew, in Kyang-nan. Soon after he made himself master of Nanking, having defeated the Moguls who came to his relief. In December 1356, he was able to raise 100,000 men, at the head of whom he took the city of U-chew, in the east borders of *Quangsi*; and here, assembling his generals, it was resolved neither to commit slaughters nor to plunder. The most formidable enemy he had to deal with was *Chen-yew-lyang*, styled "emperor of the Han." This man being grieved at the progress made by Chu, equipped a fleet, and raised a formidable army, in order to reduce Nan-chang-fu, a city of Kyang-li, which his antagonist had made himself master of. The governor, however, found means to inform Chu of his danger, upon which that chief caused a fleet to be fitted out at Nanking, in which he embarked 200,000 soldiers. As soon as *Chen-yew-lyang* was informed of his enemy's approach, he raised the siege of Nan-chang-fu, and gave orders for attacking Chu's naval force. An engagement ensued between a part of the fleets, in which Chu proved victorious; and next day, all the squadrons having joined, in order to come to a general engagement, Chu gained a second victory, and burnt 100 of the enemy's vessels. A third and fourth engagement happened, in both which Chu gained the victory; and in the last, *Chen-yew-lyang* himself was killed, his son taken prisoner, and his generals obliged to surrender themselves, with all their forces and vessels.

In January 1364, Chu's generals proposed to have He proclaimed emperor; but this he declined, and at first contented himself with the title of King of U. In February he made himself master of *Vu-chang-fu*, capital of *Hu-quang*; where, with his usual humanity, he relieved those in distress, encouraged the literati, and would allow his troops neither to plunder nor destroy. This wise conduct procured him an easy conquest both of *Kyang-li* and *Hu-quang*. The Chinese submitted to him in crowds, and professed the greatest veneration and respect for his person and government.

All this time Shun-ti, with an unaccountable negligence, never thought of exerting himself against Chu; but continued to employ his forces against the rebels who had taken up arms in various parts of the empire; so that Chu found himself in a condition to assume the title of emperor. This he chose to do at Nanking on the first day of the year 1368. After this his troops

In the third month, Chu, who had now taken the title of *Hong-yu* or *Tay-tyi*, reduced the fortresses of Tong-quin, after which his troops entered Pecheli from Honan on the one side, and Shan-tong on the other. Here his generals defeated and killed one of Shun-ti's officers; after which they took the city of Tong-chew, and then prepared to attack the capital, from which they were now but 12 miles distant. On their approach the emperor fled with all his family beyond the great wall, and thus put an end to the dynasty of Ywen. In 1370 he died, and was succeeded by his son, whom the successor of Hong-yu drove beyond the Kobi or Great Desert, which separates China from Tartary. They continued their incursions, however, for many years; nor did they cease their attempts till 1583, when vast numbers of them were cut in pieces by the Chinese troops.

China again conquered by the Tartars.

The 21st dynasty of Chinese emperors, founded in 1368 by Chu, continued till the year 1644, when they were again expelled by the Tartars. The last Chinese emperor was named Whay-tsong, and ascended the throne in 1623. He was a great lover of the sciences, and a favourite of the Christians; though much addicted to the superstitions of the Bonzes. He found himself engaged in a war with the Tartars, and a number of rebels in different provinces. That he might more effectually suppress the latter, he resolved to make peace with the former; and for that end sent one of his generals, named *Tuen*, into Tartary, at the head of an army, with full power to negotiate a peace; but that traitor made one upon such shameful terms, that the emperor refused to ratify it. Ywen, in order to oblige his master to comply with the terms made by himself, poisoned his best and most faithful general, named *Mau-ven-long*; and then desired the Tartars to march directly to Peking, by a road different from that which he took with his army. This they accordingly did, and laid siege to the capital. Ywen was ordered to come to its relief; but, on his arrival, was put to the torture and strangled; of which the Tartars were no sooner informed, than they raised the siege, and returned to their own country. In 1636, the rebels above-mentioned composed four great armies, commanded by as many generals; which, however, were soon reduced to two, commanded by Li, and Chang. These agreed to divide the empire between them; Chang taking the western provinces, and Li the eastern ones. The latter seized on part of Shen-ti, and then of Honan, whose capital, named Kay-fong-fu, he laid siege to, but was repulsed with loss. He renewed it six months after, but without success; the besieged clung rather to feed on human flesh than surrender. The Imperial forces coming soon after to its assistance, the general made no doubt of being able to destroy the rebels at once, by breaking down the banks of the Yellow River; but unfortunately the rebels escaped to the mountains, while the city was quite overflowed, and 300,000 of the inhabitants perished.

After this disaster, Li marched into the provinces of Shen-ti and Honan; where he put to death all the mandarins, exacted great sums from the officers in place, and shewed no favour to any but the populace,

whom he freed from all taxes: by this means he drew so many to his interest, that he thought himself strong enough to assume the title of emperor. He next advanced towards the capital, which, though well garrisoned, was divided into factions. Li had taken care to introduce before-hand a number of his men in disguise; and by these the gates were opened to him the third day after his arrival. He entered the city in triumph at the head of 300,000 men; whilst the emperor kept himself shut up in his palace, busied only with his superstitions. It was not long, however, before he found himself betrayed; and, under the greatest consternation, made an effort to get out of the palace, attended by about 600 of his guards. He was still more surprised to see himself treacherously abandoned by them, and deprived of all hopes of escaping the insults of his subjects. Upon this, preferring death to the disgrace of falling alive into their hands, he immediately retired with his empress, whom he tenderly loved, and the prince's her daughter, into a private part of the garden. His grief was so great that he was not able to utter a word; but the soon understood his meaning, and, after a few silent embraces, hanged herself on a tree in a silken robe. Her husband staid only to write these words on the border of his vest: "I have been basely deserted by my subjects; do what you will with me, but spare my people." He then cut off the young prince's head with one stroke of his scymitar, and hanged himself on another tree, in the 17th year of his reign, and 36th of his age. His prime minister, queens, and eunuchs, followed his example; and thus ended the Chinese monarchy, to give place to that of the Tartars, which hath continued ever since.

It was some time before the body of the unfortunate monarch was found. At last it was brought before the rebel Li, and by him used with the utmost indignity; after which he caused two of Whay-tsong's sons, and all his ministers, to be beheaded; but his eldest son happily escaped by flight. The whole empire submitted peaceably to the usurper, except prince U-fan-ghey, who commanded the imperial forces in the province of Lyau-tong. This brave prince, finding himself unable to cope with the usurper, invited the Tartars to his assistance, and Tsong-te their king immediately joined him with an army of 80,000 men. Upon this the usurper marched directly to Peking; but not thinking himself safe there, plundered and burnt the palace, and then fled with the immense treasure he had got. What became of him afterwards we are not told; but the young Tartar monarch was immediately declared emperor of China, his father Tsong-te having died almost as soon as he set his foot in that empire.

The new emperor, named *Shun-chi*, or *Xun-chi*, began his reign with rewarding U-fan-ghey, by conferring upon him the title of King; and assigned him the city of Si-gnan-fu, capital of Shen-ti, for his residence. This, however, did not hinder U-fan-ghey from repenting of his error in calling in the Tartars, or, as he himself used to phrase it, "in sending for lions to drive away dogs." In 1674, he formed a very strong alliance against them, and had probably prevailed if his allies had been faithful. But they treacherously deserted him one after another; which so affected him,

China.

48

than

China.

that he died soon after. In 1681 Hong-wha, son to U-san-ghyey, who continued his efforts against the Tartars, was reduced to such straits that he put an end to his own life.

During this space, there had been some resistance made to the Tartars in many of the provinces. Two princes of Chinese extraction had at different times been proclaimed emperors; but both of them were overcome and put to death. In 1682, the whole 15 provinces were so effectually subdued, that the emperor Kang-hi, successor to Shun-chi, determined to visit his native dominions of Tartary. He was accompanied by an army of 70,000 men, and continued for some months taking the diversion of hunting. This he continued to do for some years; and in his journeys took father Verbiest along with him, by which means we have a better description of these countries than could possibly have been otherwise obtained. This prince was a great encourager of learning, and of the Christian religion; in favour of which last he published a decree, dated in 1692. In 1716, however, he revived some obsolete laws against the Christians, nor could the Jesuits with all their art preserve the footing they had got in China. The causes of this alteration in his resolution are, by the missionaries, said to have been the slanders of the mandarins; but, from the known character of the Jesuits, it will be readily believed, that there was something more at bottom. This emperor died in 1722, and was succeeded by his son Yong-ching; who not only gave no encouragement to the missionaries, but persecuted all Christians of whatever denomination, not excepting even those of the imperial race. At the beginning of his reign he banished all the Jesuits into the city of Canton, and in 1732 they were banished from thence into Ma-kau, a little island inhabited by the Portuguese, but subject to China. He died in 1736; but though the Jesuits entertained great hopes from his successor, we have not heard that they have yet met with any success.

Thus we have given an account of the most memorable transactions recorded in the Chinese history. It now remains only to describe the present state of the empire and its inhabitants, according to the best and latest accounts.

The division of China into 15 provinces, we have already mentioned. In such a vast tract of country, it is impossible that either the climate or soil should be alike in all places. The climate, however, is, in general, reckoned very moderate, except in the northern provinces, where the cold is extremely piercing, owing to the high ridges of mountains with which those parts are intersected, and which are always covered with snow. Even in those parts which lie under the tropics, the winds that blow from the northern mountains, make the winter, which continues for three or sometimes four months, extremely cold and piercing. The southern parts are excessively hot and dry; but the heats are more easily borne by means of the cooling grooves, groves, &c. to which the inhabitants retire in the heat of the day, when there is the same universal silence and cessation from business as if it was midnight. These parts have neither frost nor snow; but are much troubled with storms and violent rains, about the time of the equinoxes, especially the

autumnal, which is all the winter they have. They enjoy a serene sky all the rest of the year. It is, however, universally acknowledged, that where nature has been most unequal in the distribution of her gifts, the inhabitants have remedied these inconveniences as far as human industry could go. In some provinces, they have levelled whole ridges of mountains; in others, they have raised artificial ones. In some, they have provided fences against excessive colds; in others, against heats and droughts, &c. In short, by varying their agriculture, manuring, and planting, according to the differences of soils and climates, almost every spot throughout this vast empire produces more than enough to make its inhabitants rich and happy. All these advantages are farther improved by the vast number of canals cut from one river to another, and the innumerable carriages they keep up by land, by which each canton may easily communicate its own peculiar product to all the rest.

On these accounts, the Chinese entertained the most extraordinary opinion of themselves and their country. The advantages they had over those neighbouring nations they knew or heard of, appeared to them so considerable, that they looked upon themselves as the only favourites of heaven, and the rest of mankind as barbarians, whom they represented as monsters, dwarfs, and contemptible creatures. They looked upon their country to be placed in the centre of the earth; and themselves as the only people who had a human shape or form. All the other kingdoms or nations, the number of which they imagined might amount to 72, were scattered about in small islands, the biggest of which, according to their maps, was not so large as the least of the Chinese provinces. These were stuck round their empire, to which they gave a quadrangular form, like as many satellites, designed only to serve and adorn it. They indeed gave the preference to their four neighbouring kingdoms of Tartary, Japan, Ton-king, and Korea. The inhabitants of these, though reckoned barbarians, they still looked upon as considerably improved by their vicinity to China: but as to the rest, they were looked upon as outcasts into the extreme parts of the earth, and the refuse of nature; and as such they characterized them in their maps, marking them by such emblems as were most fit to inspire their nation with disdain and contempt. It was therefore no small matter of wonder to them, when, upon their becoming acquainted with the Europeans, they found them not only as polite and rational as themselves, but far superior to them in all kinds of learning. From that time they used to say that "the Chinese had two eyes, the Europeans one, and the rest of the world none at all."

When the country was first discovered by the Europeans, they were no less surprised at the ingenuity and politeness of the Chinese, than the latter were at the learning of the Europeans. The first traveller that we know of who visited China, was Fra. Paulo, more commonly known by the name of *Paulus Venetus*, about the end of the 13th century. At that time all Europe was immersed in such a state of barbarism, that the riches and polite behaviour of the Chinese could not but appear very extraordinary in his eyes. His accounts were not believed, but laughed at as a romance.

romance. When the Portuguese discovered the famous country by sea, above 200 years ago, they were almost as much surprised as Paulus Venetus had been. Neither were their accounts credited, till the missionaries whom the pope kept pouring in since the year 1580 published so many accounts concerning the riches of China that they could no longer be denied. It must be owned, however, that the Chinese were vastly inferior to the Europeans in the liberal sciences; but, on the other hand, the former, to this day, as much exceed them in opulence, manufactures, handicrafts, agriculture, &c.

55
Incredible
numbers of
people.

Another advantage for which this country hath been famed, and in which it certainly exceeds every other in the world, is the vast number of its inhabitants. In most of the provinces, the cities, towns, and villages, are so thick crowded upon one another, that the whole seems to be almost a continued town. All of them swarm with inhabitants, every one employed in some manufacture, traffic, or work. Their roads are crowded with passengers night and day, with coaches, carriages, waggons, and sometimes whole caravans; all employed in carrying on some useful commerce, and in conveying all sorts of merchandizes, provisions, and other wares, from one end of the kingdom to the other. The number of armies, garrisons, and troops necessary for defending this vast empire, far exceed what is to be found in any other part of the world, and indeed are almost incredible. According to some Chinese registers, the whole number of males amounted to 59,788,364; at that time the army consisted of 902,054 foot, and 989,167 horse, besides 767,970 men kept in garrisons. For these, as well as for the accommodation of the mandarins and other officers of the court, there are reckoned 1145 inns or places of entertainment. In short, to speak in the style of one of their writers, "the Chinese empire is so immensely populous, that its inhabitants are not to be computed by thousands, but by millions." Many of these live entirely in vessels on the canals, keeping hogs, poultry, dogs, and other domestic animals, on board. Besides these vessels, there is a prodigious number of floats of timber which perpetually go up and down the canals and rivers, carrying whole villages of people upon them. Some of these floats are above a mile in length. The people build huts upon the floats, and live in them till they have disposed of their timber, which they sometimes carry 1000 miles.

56
Extreme
misery of
the great-
est part of
them.

From this description, it is natural to imagine that the Chinese must be the happiest nation in the whole world, and that poverty is scarce known among them; but the case is far otherwise. This empire exceeds other nations as much in the misery of many of its inhabitants, as it does in the number of them. This is in a great measure owing to the wickedness and corruption of their magistrates. Every province has its viceroy and several orders of mandarins, who are designed to serve as checks upon each other, and pervert the people from oppressing one another, or being oppressed by their governors. But the misfortune is, that they all find it their interest to wink at one another's crimes; and thus the people are oppressed to a degree beyond what they could be by any single governor however bad. The first class of mandarins

are the judges of courts, who determine civil and criminal causes; the next attend the affairs of the treasury and revenue; and the third command the militia. All these, according to the Chinese constitution, ought to keep their offices no longer than three years; and are never to be natives of the province where they officiate; lest, if they be of mean descent, they should be despised; or, if rich, should become too much respected and powerful. They are allowed sufficient salaries, that they may be enabled to discharge their offices, and administer justice without fees or bribery. Their palaces and places of residence are also provided for them at the expence of government, to prevent them from being too profuse in furniture, &c. But all these wise regulations they find means to elude; and there is not a nation on earth where extortion and fraud are carried to a greater height, or more universally diffused, than in China. Thus the court at Peking extorts vast sums from the viceroys of the provinces, and these again from the mandarins under them. The mandarins of course must fleece the inferior officers, and they again plunder the people, who having none below them whom they can oppress, are reduced to the necessity of cheating one another, or those foreigners who trade with them. In this they are so expert, that it is commonly said a Chinese will cheat a man of any other nation; but none can cheat a Chinese, except one of his own country.

The consequence of this extortion is manifest, in the misery to which the lower ranks of inhabitants are reduced in years of dearth: which sometimes happen through excessive drought, or the devastations of the grasshoppers; which, in some parts of the empire, at times, appear in such numbers, as not only to devour every herb, leaf, or fruit, but even the small wood of the branches, and fibres of the roots of trees. In these calamitous cases, the common people are often obliged to expose or destroy their children, sell them for slaves, and sometimes to rise in rebellion. Even in their most plentiful seasons, the poorer sort, notwithstanding all their art and industry, are glad to support themselves not only on the very refuse of every kind of provisions, but even on dogs and cats, though they die of old age or sickness, rats, mice, and other vermin; or on the garbage of any fowl, fish, or fowl, they can purchase; for these are sold in the markets as well as the more dainty meats; and there are cooks-shops where the entrails of fitches, fowls, &c. are dressed, and whither those who can afford no better are glad to repair.

57
Govern-
ment.

The government of China is monarchical, and in the highest degree despotic; and has been so from the earliest ages. Nay, so much were they inured to this kind of government, and so little notion had they of any other, that when the Dutch ambassador made his first application, he found it very difficult to make the court understand what he meant by the "High and mighty lords the states general, and the republic of Holland." Their laws are contained in some books which they call canonical; but their monarchs are the sole interpreters of them; so that we may say the whole legislative power is lodged in their breast, and depends entirely on their will.

The revenue of the emperor is computed at about 50,000,000

50,000,000 Sterling. Their punishments are either capital, as in cases of rebellion, murder, treason, &c. or corporal and pecuniary in lesser crimes. Rebellion and treason being esteemed the greatest of all possible crimes are punished with the greatest rigour, viz. by cutting the criminal into 10,000 pieces, in the following manner: the executioner, having first tied him to a stake, tears the skin off his head and forehead, and lets it hang over his eyes, to prevent him, according to some, from seeing how dreadfully the rest of his body is mangled. Then he proceeds to flay the other parts of his body with a kind of cutlase, till he hath almost cut all his flesh in pieces; and then abandons him to the populace, who commonly dispatch him in the same butcherly manner. This punishment, however, is seldom executed with such extreme rigour, unless under some cruel princes; for the law only directs the body of the criminal to be cut into several pieces, his belly ripped up, and his entrails taken out, after which the carcase is to be thrown into a ditch or river, as is commonly done to great malefactors.

Next to treason or rebellion against the emperor, that against parents is reckoned the greatest crime, and is punished with equal severity. In this case, if a father accuses a son before a magistrate, no further proof is required, but the criminal is immediately executed. This is done for mere obstinacy or disobedience; but if the offender hath proceeded so far as mockery, insult, or lifting a hand, the whole country is alarmed, and the punishment of the criminal reserved for the emperor himself. In this last case, the magistrates of the place are turned out with disgrace, and the whole neighbourhood is threatened with some severe punishment for having given birth to such a monster. The offender is then condemned to be cut like a traitor or rebel, into 10,000 pieces, and afterwards burnt; his lands, house, or houses, to be destroyed, and to remain so, as a monument of such a detestable crime.

Murder is also capital, and is punished either by beheading or strangling the criminal. The former of these is reckoned the most dishonourable; because, in that case, the head, which is the most honourable part, is separated from the body, and the person doth not go out of the world with the body intire, as when he came into it. Adultery is so far from being a capital crime in China, that some fond parents, out of compassion to their daughter's weakness, will contract with their future husbands, in consideration of some valuable present, to allow her the liberty of now and then indulging herself with a gallant, without being called to an account for it. But where no such contract hath been made, the husband may inflict a corporal punishment, or divorce a wife who proves unfaithful. Neither is theft capitally punished. Those who are guilty of it, are either condemned to the bastinado, that is, to receive such a number of blows with a cudgel on their backs or buttocks as the magistrate shall appoint. After this, if the offender is able, he must kneel down before him, and thank him for his kind correction; though one blow would be sufficient to lame a man, if the executioner was not bribed. When the theft is of a higher nature, the offender is condemned to the *kan-ghe*, or wooden

ruff. This is a kind of portable pillory, consisting of two pieces of wood hollowed out in the middle, so as to fit the neck of the offender, and of such a breadth, that the wearer can neither see his own feet, nor put his hand to his mouth, so that he must be beholden to some other person for his food. It is made lighter or heavier according to the nature of the crime, or the favour of the mandarin: the lightest are about 40 or 50 pounds weight, but many weigh much more; some even 200 pounds; and so troublesome and grievous are these collars, that the wearers often die. The time of wearing is likewise appointed by the mandarin; as also the place where it is to be worn. When the time is expired, the offender is brought back to the mandarin; and after a suitable admonition, and a sound drubbing, which begins and ends every punishment of this kind, he is released from his burden, and set at liberty.

There are two kinds of torture used in China, the ordinary and extraordinary. The first is inflicted by a kind of engine, which they clap on the hands or feet, or both; and which distorts the bones to such a degree that the ankles are sometimes squeezed quite flat by it. The extraordinary torture is seldom used, except in cases of treason or rebellion, in order to make the criminal discover his accomplices after the fact has been proved. It is inflicted by cutting slight gashes in the body, and stripping off the skin in narrow slips or fillets. One thing, however, must be said in praise of the Chinese, with regard to the treatment of their criminals, viz. that their prisons are much more capacious, airy, and sweet, than any of the European ones. They are generally large spacious courts, on whose four sides are the apartments of the criminals, raised upon wooden columns, in the form of a gallery; and on the four corners are secured the most notorious rogues, in strong cells and fetters. The women are confined in a separate court, and no man is admitted to come or even speak to them; except through a grate, or the turning-box, through which their victuals, and other necessities are conveyed.

As to their persons, the Chinese are generally of middling stature, broad faced, with black hair, small black eyes, short noses, and thin beards. This last circumstance is the effect of a very painful operation, viz. pulling up the greatest part of the beard by the roots with tweezers. Since the accession of the Tartar monarchs to the crown, they have forced the Chinese to cut off all their hair except a lock on the crown like the Mahometans. Near the tropic, their complexions incline to tawny; but in the northern part, they are as fair as other people under the same parallel. The women are esteemed for their little feet, which are reckoned their greatest beauty: and in order to form them little, they are bound up from their infancy so tight, that they cannot grow to the common size; the foot of a full grown woman not being bigger than that of a child of four years old. The men wear a cap of the shape of a bell on their heads, which does not cover their ears; they also wear a vest and sash, and over the vest a loose coat or gown, and a kind of silk boots quilted with cotton. In the southern provinces the inhabitants, when at home, throw off every

ry thing but a pair of drawers, and appear naked ; as the common people also do on the streets. The women dress with their hair down, having nothing on their heads, in the south. They generally wear a silk vest, red, blue, or green ; and over it a loose gown with white sleeves, and embroidered felt shoes ; but, by reason of the smallness of their feet, hobble prodigiously when they walk. Here, as in most other countries of the east, the married couple are brought together without any previous acquaintance with each other ; the bargain being struck by the parents, or by some go-between, and afterwards ratified by presents sent on both sides. There is scarce any country in the world where grief for the dead is manifested to such a degree, as in China, especially for near relations ; or where the mourning is so deep, and so long continued. Every Chinese keeps in his house a table whereon are written the names of his father, grandfather, and great-grandfather ; before which they frequently prostrate themselves ; and when the father of a family dies, the name of the great-grandfather is taken away, and that of the deceased added to make up the number.

61

Religion.

The Chinese are said to worship one supreme God along with several inferior deities, who appear to have been men eminent in several ages ; particularly the inventors of arts and sciences. There are at this day three sects in China. 1. The followers of La-lao-kun, who lived above 500 years before Christ. He taught that God was corporeal, and had many subordinate deities under his government. His disciples study magic, and pretend to make a drink that will confer immortality. The second is the sect of the learned, or disciples of Confucius. He left many admirable precepts in morality, and instructed the people in philosophy. He speaks of God as a most pure and perfect principle, and the fountain and essence of all beings. Though we are told that he prohibited idolatry, he has temples and images erected to him, and is worshipped with the most profound veneration ; as appears from the pope's decree against the Jesuits, for indulging their converts in this idolatrous worship. The third sect, which is that of the idol Fo, or Fo-hi, is much more numerous than either of the former. They style him the only saviour of the world. His priests, the bonzes, teach several moral precepts, and a state of rewards and punishments after this life. The punishments consist chiefly in animating some vermin, or beast of burden after death. They forbid the drinking of wine ; and do not forget to instruct their followers how much it is their duty to entertain and nourish their priests, and to build them temples and monasteries, and perform the penances they enjoin. If these things are neglected, they threaten them with the most unhappy transfigurations. The Chinese have also an image of immortality, which they worship under the shape of a monstrous fat man sitting cross-legged, with a huge prominent belly. There is another called the *Idol of Pleasure*, about 20 feet high ; and between these, in their temples is an image 30 feet high, gilded over, with a crown upon his head, and richly dressed. The Christian religion, we are told, was planted in this country, either by the apostle Thomas, or some of his disciples. The Chinese re-

cords seem to intimate that a man came there about that time, who preached a heavenly doctrine, and confirmed it by miracles. There is also an ancient marble pillar erected in the province of Shen-si, in memory of a man that brought Christianity thither in the year 636. However, the missionaries of the church of Rome did not find, as we are told, the least vestige of Christianity on their arrival in China.

62

Learning.

The learning of the Chinese is, in a great measure, confined to the study of their own language. Their characters are a kind of short-hand, every one of which signifies a word or sentence. There are near 60,000 of these characters in all, but those in common use do not exceed 3000. This vast number of characters, however, is reducible to a pure and simple alphabet like those of any other language : for a character is no more than a word written with its proper consonants and vowels ; not indeed at length as we do, but intermingled one with another by some peculiar method known only to them, or perhaps only to their learned men. They write from the top to the bottom of the page. In all other respects the knowledge and learning of the Chinese are very limited. Some knowledge of astronomy they certainly had ; but that was exceedingly defective. They are said indeed to have calculated the eclipses of the sun and moon for a vast number of years ; but many of these calculations have been found by the Europeans who visited them to be false and erroneous, and whatever progress they have made in that or other sciences must be attributed entirely to the Jesuit missionaries. They are, however, in some things a very ingenious people. The art of printing they have had from time immemorial. It is true, this is only performed by wooden blocks in the same manner as cards are done among us ; but the vast number of their characters renders it impossible to bring that art to the same perfection which it hath attained in Europe. Their chief commodities are, silk, cotton, tea, china-ware, and cabinets or lacquered-ware. Their silks are exceedingly fine ; their atlas's, gold and silver stuffs, are not to be paralleled ; but their porcelain is thought to be equalled or even excelled by that of Dresden, and their lacquered-ware is greatly excelled by that of Japan. In hard-ware the Europeans excel them prodigiously ; the Chinese being mere bunglers at making clocks, watches, door and gun-locks, &c. They had the use of gun-powder, and of the mariner's compass, for many centuries before they were known in Europe ; but through a neglect unaccountable in such an ingenious people they scarce reaped one single advantage either from the one or the other.

63

Navigation.

The Chinese had no traffic with other nations, except those in their neighbourhood, till the Portuguese discovered their country by the way of the Cape of Good Hope. Their junks, as they are called, are many of them 1000 tons burthen, heavy sailers, with square heads and stems. Some of them have two masts, others three, but never any top-masts ; and their sails are made of matting, which they let down upon the deck when they furled them. The hold of the ship is divided into many small partitions, which are made so tight, that if a leak happens in one of them it goes no further, and the goods stowed in the other partitions

China-root
I
Chio.

partitions receive no damage. The compilers of the Universal History take notice, that the Chinese vessels are built according to the proportions of Noah's ark; viz. six breadths to a length: and this they will have to be a proof that the Chinese empire was founded by Noah. They have no coin throughout the whole empire, except a copper one of very little value. Their merchandize is bought with gold and silver cut for the purpose, from ingots or plates. The former is of less value in China than in most other nations; and therefore silver is advantageously exchanged by the Europeans for that precious metal.

CHINA-Root, in the materia medica, the root of a species of *SMILAX*, brought both from the East and West Indies; and thence distinguished into oriental and occidental. Both sorts are lengthy, full of joints, of a pale-reddish colour, with no smell, and very little taste. The oriental, which is the most esteemed, is considerably harder and paler-coloured than the other. Such should be chosen as is fresh, close, heavy, and upon being chewed appears full of a fat unctuous juice. It is generally supposed to promote insensible perspiration and the urinary discharge, and by its unctuous quality to obtund acrimonious juices. China-root was first brought into Europe in the year 1535, and used as a specific against venereal and cutaneous disorders. With this view it was made use of for some time; but has long since given place to more powerful medicines.

CHINA-Ware. See **PORCELAIN**.

CHINCA, a sea-port town of Peru in South America, situated in an extensive valley of the same name, in W. Long. 76. o. S. Lat. 13. o.

CHIN-COUGH, a convulsive kind of cough to which children are generally subject. See (the *Index* subjoined to) **MEDICINE**.

CHINESE, in general denotes any thing belonging to China, or its inhabitants.

CHINESE Swanpan. See **SWANPAN**.

CHINKAPIN. See **FAGUS**.

CHINON, an ancient town of Tourain in France, remarkable for the death of Henry II. king of England, and for the birth of the famous Rabelais. It is seated on the river Vienne, in a fertile and pleasant country, in E. Long. o. 18. N. Lat. 47. 2.

CHIO, or **CHIOS**, an Asiatic island lying near the coast of Natolia, opposite to the peninsula of Ionia. It was known to the ancients by the name of *Æthalia*, *Macris*, *Pithyusa*, &c. as well as that of Chios. According to Herodotus, the island of Chios was peopled originally from Ionia. It was at first governed by kings, but afterwards the government assumed a republican form; which, by the direction of Isocrates, was modelled after that of Athens. They were, however, soon enslaved by tyrants, and afterwards conquered by Cyrus king of Persia. They joined the other Grecians in the Ionian revolt; but were shamefully abandoned by the Samians, Lesbians, and others of their allies; so that they were again reduced under the yoke of the Persians, who treated them with the utmost severity. They continued subject to them till the battle of Mycale, when they were restored to their ancient liberty, which they enjoyed till the downfall of the Persian empire, when they became

Chionanthus
I
Chirographer

subject to the Macedonian princes. In the time of the emperor Vespasian the island was reduced to the form of a Roman province; but the inhabitants were allowed to live according to their own laws under the superintendence of a prætor. It is now subject to the Turks; and is called *Scio*; see that article.

CHIONANTHUS, the **SNOW-DROP TREE**; a genus of the monogynia order, belonging to the dianthia class of plants. There is but one species particularly described by botanists, viz. the *Virginica* or *fringe-tree*. It is common in Virginia and South Carolina, where it grows by the sides of rivulets. It rises to the height of ten feet; the leaves are as large as those of the laurel, but much thinner. The flowers come out in May, and are of a pure white; from whence it has the name of the *snow-drop tree*. They hang down in large branches, and are cut into narrow segments; from which it has got its other name of the *fringe-tree*. After the flowers are fallen off, the fruit appears, which grows to the size of a sloe, having a stone in the middle. The plants are propagated from seeds sown on a hot-bed, and kept in a stove. Some have been raised from layers; but this method is very precarious, and therefore the other is to be preferred. The seeds must be procured from America, for they never come to perfection in this country.

CHIOURLIC, an ancient town of Turkey in Europe, and in Romania, with a see of a Greek bishop. It is seated on a river of the same name, in E. Long. 7. 47. N. Lat. 41. 18.

CHIOZZO, an ancient and handsome town of Italy, in the territory of Venice, and in a small island, near the Lagoon, with a podestà, a bishop's see, and a harbour defended by a fort. E. Long. 12. 23. N. Lat. 45. 17.

CHIPPENHAM, a town of Wiltshire, seated on the river Avon. It is a good thorough-fare town; has a handsome stone-bridge over the river, consisting of 16 arches; and sends two members to parliament. W. Long. 2. 12. N. Lat. 51. 25.

CHIROGRAPH, was anciently a deed which, requiring a counterpart, was engrossed twice on the same piece of parchment, counterwise; leaving a space between, wherein was wrote **CHIROGRAPH**; through the middle whereof the parchment was cut, sometimes straight, sometimes indentedly; and a moiety given to each of the parties. This was afterwards called *dividenda*, and *charta divisæ*; and was the same with what we now call *charter-party*. See **CHARTER-Party**. The first use of these chirographs with us, was in the time of Henry III.

CHIROGRAPH was also anciently used for a fine: and the manner of engrossing the fines, and cutting the parchment in two pieces, is still retained in the office called the *chirographer's office*.

CHIROGRAPHER of **FINES**, an officer in the common pleas, who engrosses **FINES** acknowledged in that court, into a perpetual record, (after they have been examined, and passed by other officers;) and writes and delivers the indentures thereof to the party. He makes two indentures; one for the buyer, the other for the seller; and a third indented piece, containing the effect of the fine, and called the *foot of the fine*; and delivers it to the *custos brevium*.—The

same

Chiromancy.
Chiron.

same officer also, or his deputy, proclaims all fines in court every term, and endorses the proclamations on the backside of the foot; keeping, withal, the writ of covenant, and the note of the fine.

CHIROMANCY, a species of divination drawn from the lines and lineaments of a person's hand; by which means, it is pretended, the dispositions may be discovered. See **DIVINATION**, n° 9.

CHIRON, a famous personage of antiquity; styled by Plutarch, in his dialogue on music, "*The wife Centaur*." Sir Isaac Newton places his birth in the first age after Deucalion's deluge, commonly called the *Golden Age*; and adds, that he formed the constellations for the use of the Argonauts, when he was 88 years old; for he was a practical astronomer, as well as his daughter Hippo: he may, therefore, be said to have flourished in the earliest ages of Greece, as he preceded the conquest of the Golden Fleece, and the Trojan war. He is generally called the son of Saturn and Philyra; and is said to have been born in Thesfaly among the **CENTAURS**, who were the first Greeks that had acquired the art of breaking and riding horses: whence the poets, painters, and sculptors, have represented them as a compound of man and horse; and perhaps it was at first imagined by the Greeks, as well as the Americans, when they first saw cavalry, that the horse and the rider constituted the same animal.

Chiron was represented by the ancients as one of the first inventors of medicine, botany, and *chirurgery*; a word which some etymologists have derived from his name. He inhabited a grotto or cave in the foot of Mount Pelion, which, from his wisdom and great knowledge of all kinds, became the most famous and frequented school throughout Greece. Almost all the heroes of his time were fond of receiving his instructions; and Xenophon, who enumerates them, names the following illustrious personages among his disciples: Cephalus, Æsculapius, Melanion, Nestor, Amphiaræus, Peleus, Telamon, Meleager, Theseus, Hippolitus, Palamedes, Ulysses, Menestheus, Diomedes, Castor and Pollux, Machaon and Podalirius, Antilochus, Æneas, and Achilles. From this catalogue it appears, that Chiron frequently instructed both fathers and sons; and Xenophon has given a short eulogium on each, which may be read in his works, and which redounds to the honour of the preceptor. The Greek historian, however, has omitted naming several of his scholars, such as Bacchus, Phœnix, Cocytus, Arylæus, Jason, and his son Medeus, Ajax, and Protefilaus. Of these we shall only take notice of such as interest Chiron more particularly. It is pretended that the Grecian Bacchus was the favourite scholar of the Centaur: that he learned of this master the revels, orgies, bacchanalia, and other ceremonies of his worship. According to Plutarch, it was likewise at the school of Chiron that Hercules studied music, medicine, and justice; though Diodorus Siculus tells us, that Linus was the music-master of this hero. But among all the heroes who have been disciples of this Centaur, no one reflected so much honour upon him as Achilles, whose renown he in some measure shared; and to whose education he in a particular manner attended, being his grandfather by the mother's side. Apollo-

Burney's
Hist. of
Music.

dorus tells us, that the study of music employed a considerable part of the time which he bestowed upon his young pupil, as an incitement to virtuous actions, and a bridle to the impetuosity of his temper. One of the best remains of antique painting now existing, is a picture upon this subject, dug out of the ruins of Herculanæum, in which Chiron is teaching the young Achilles to play on the lyre. The death of this philosophic musician was occasioned, at an extreme old age, by an accidental wound in the knee with a poisoned arrow, shot by his scholar Hercules at another. He was placed after his death by Mæzus among the constellations, through respect for his virtues, and in gratitude for the great services which he had rendered the people of Greece. Sir Isaac Newton says*, * *Chronol.* p. 151. in proof of the constellations being formed by Chiron and Mæzus for the use and honour of the Argonauts, that nothing later than the expedition was delineated on the sphere; according to the same author, Chiron lived till after the Argonautic expedition, in which he had two grandsons. The ancients have not failed to attribute to him several writings; among which, according to Suidas, are *precepts*, *υποθεσεις*, in verse, composed for the use of Achilles; and a medicinal treatise on the *diseases incident to horses* and other quadrupeds, *ἰαματρικος*; the lexicographer even pretends, that it is from this work the Centaur derived his name. Fabricius gives a list of the works attributed to Chiron, and discusses the claims which have been made for others to the same writings; and in vol. xiii. he gives him a distinguished place in his catalogue of ancient physicians.

CHIRONIA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants. There are eight species, of which the *fruticosa* is the most remarkable. It is a native of the Cape of Good Hope. The root is fibrous, and spreads near the surface of the ground. The stalks are round, and inclining to be ligneous, but are of a very soft texture; these rise from two to three feet high, sending out several branches which grow erect, and are garnished with succulent leaves an inch or more in length, and about an eighth of an inch in breadth. At the end of each shoot the flowers are produced, which are tubulous, and spread open at the top; they are of a bright red colour; and when there are a large number of flowers open on the same plant, they make a fine appearance. The flowers are produced from June to autumn; and the seeds ripen in October. The plants are propagated by seeds, which must be sown in pots filled with light sandy earth, and plunged in a moderate hot-bed. In summer they may be inured to the open air; but must always be sheltered in winter.

CHIRONOMY, in antiquity, the art of representing any past transaction by the gestures of the body, more especially by the motions of the hands: this made a part of liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIROTONY, among ecclesiastical writers, denotes the imposition of hands used in conferring priestly orders. However, it is proper to remark, that chirotony originally was a method of electing magistrates, by holding up the hands.

Chironia
Chirotony.

CHIRURGEON,

CHIRURGEON, or SURGEON. See SURGEON. CHIRURGERY. See SURGERY. CHISLEY-LAND, in agriculture, a soil of a middle nature between sandy and clayey land, with a large admixture of pebbles.

CHISEL, a well known instrument much used in carpentry, masonry, joinery, sculpture, &c.

CHITAU, in the materia medica, a kind of lignum aloes. See LIGNUM Aloes.

CHITON, in zoology, a genus of the order of vermes testacea. The name *chiton* is from *χiton*, *Corica*, a coat of mail. The shell is plated, and consists of many parts lying upon each other transversely: the inhabitant is a species of the DORIS. They are common on the shores of Scarborough, Aberdeen, and Lochbroom. See several species represented of their natural size on Plate LXXIV.

CHITTRICK'S MEDICINE for the STONE. This medicine was some years ago kept as a secret, and had great reputation as a lithontriptic, which indeed it seems in many cases to deserve. It was discovered by Dr Blackrie to be no other than soap-lye, and the following receipt for using it was procured by General Dunbar: "Take one tea-spoonful of the strongest soap-lye, mixed in two table-spoonfuls of sweet milk, an hour before breakfast, and at going to bed. Before you take the medicine take a sup of pure milk, and immediately after you have swallowed the medicine take another. If you find this agrees with you for two or three days, you may add half as much more to the dose."

CHIVALRY, in law, is used for a tenure of lands by knight's service; whereby the knight was bound to perform service in war unto the king, or the mesne lord of whom he held by that tenure. And chivalry was either general or special: *general*, when it was only in the feoffment that the tenant held *per servitium militare*, without any specification of sergeantry, escuage, &c.; *special*, when it was declared particularly by what kind of knight-service the land was held.

For the better understanding of this tenure it hath been observed, that there is no law but is holden immediately or immediately of the crown by some service; and therefore all freeholds that are to us and our heirs, are called *feuda*, or *feoda*, "fees;" as proceeding from the king for some small yearly rent, and the performance of such services were originally laid upon the land at the donation thereof. For as the king gave to the great nobles, his immediate tenants, large possessions forever, to hold of him for this or that service or rent; so they, in time, parcelled out to such others as they liked, the same lands for rents and services as they thought good: and these services were, by Littleton, divided into two kinds, *chivalry* and *sovcage*; the first whereof was martial and military, the other rustic. Chivalry, therefore, was a tenure of service, whereby the tenant was obliged to perform some noble or military office unto his lord: and it was of two kinds; either *regal*, that is, held only of the king; or *common*, where held of a common person. That which might be held only of the king was called *servitium*, or *sergeantia*; and was again divided into *grand* and *petit* serjeanty. The grand serjeanty was

where one held lands of the king by service, which he ought to do in his own person; as, to bear the king's banner or spear, to lead his host, to find men at arms to fight, &c. *Petit* serjeanty was when a man held lands of the king, to yield him annually some small thing towards his wars, as a sword, dagger, bow, &c. Chivalry that might be holden of a common person was termed *scutagium*, "escuage;" that is, service of the shield; which was either uncertain or certain.

Escuage uncertain, was likewise two-fold: first, where the tenant was bound to follow his lord, going in person to the king's wars, either himself, or sending a sufficient man in his place, there to be maintained at his expence, so long as was agreed upon between the lord and his first tenant at the granting of the fee; and the days of such service seem to have been rated by the quantity of land so holden: as, if it extended to a whole knight's fee, then the tenant was to follow his lord 40 days; and if but to half a knight's fee, then 20 days; if a fourth part, then 10 days, &c. The other kind of this escuage was called *castle-ward*, where the tenant was obliged, by himself or some other, to defend a castle as often as it should come to his turn. And these were called *escuage uncertain*; because it was uncertain how often a man should be called to follow his lord to the wars, or to defend a castle, and what his charge would be therein.

Escuage certain, was where the tenure was set at a certain sum of money to be paid in lieu of such service; as that a man should pay yearly for every knight's fee 20 s.; for half a knight's fee 10 s. or some like rate; and this service, because it is drawn to a certain rent, groweth to be of a mixed nature, not merely focage, and yet focage in effect, being now neither personal service nor uncertain. The tenure called chivalry had other conditions annexed to it: but there is a great alteration made in these things by the stat. 12. Car. 2. c. 24. whereby tenures by knight's service of the king, or any other person in capite, &c. and the fruits and consequences thereof, are taken away and discharged; and all tenures are to be construed and adjudged to be free and common focage, &c.

CHIVALRY, properly so called, and, under the idea of a distinct military order, conferred in the way of investiture, and accompanied with the solemnity of an oath, and other ceremonies, as described in the old historians and romances, seems to have sprung immediately out of the *feudal constitution*.

The first and most sensible effect of this constitution was the erection of a great number of petty tyrannies. For the power given by it to the barons over their numerous vassals was so great, that they all were in truth a sort of absolute sovereigns, at least with regard to one another. Hence, their mutual arms and interests often interfering, the feudal state was, in a good degree, a state of war; and their castles were so many fortresses, as well as palaces. In this state of things, all imaginable encouragement was to be given to the use of arms. And this condition of the times gave rise to that military institution which we know by the name of *chivalry*. Further, military discipline was not to be relaxed even in the intervals of peace.

Origin of
chivalry.

Chivalry. peace. Hence the origin of jousts and tournaments, those images of war. Chivalry was the natural, and even sober, effect of the feudal policy.

Character- The conjecture of the rise of chivalry, from the istics and genius of Chivalry. circumstances of the feudal government, accounts for the several characteristics of this singular profession.

1. The passion for arms; the spirit of enterprise; the honour of knighthood; the rewards of valour, ambition, interest, glory, all concurred, under such circumstances, to produce these effects. When this turn was given to the thoughts and passions of men, life and fashion would do the rest, and carry them to all the excesses of military fanaticism. One of the strangest circumstances in the old romances, and which looks most like a mere extravagance of the imagination, is that of the *women-warriors*; yet in this they did but copy from the manners of the times.

2. Their romantic ideas of justice; their passion for adventures; their eagerness to run to succour the distressed; and the pride they took in redressing wrongs, and removing grievances. The feudal state being a state of almost perpetual violence, rapine, and plunder, it was unavoidable that numbers of the tenants or followers of one baron should be carried away by the followers of another: and the interest each had to protect his own, would, of course, introduce the point of honour in attempting, by all means, not only to retaliate on the enemy, but to rescue the captive sufferers out of the hands of their oppressors. It would be meritorious in the highest degree to fly to their assistance, when they knew where they were to be come at; or to seek them out with diligence, when they did not. This last service they called *going in quest of adventures*; which at first, no doubt, was confined to those of their own party, but afterwards, by the habit of acting on this principle, would be extended much further. So that, in process of time, we find the knights-errant, as they were now properly styled, wandering the world over in search of occasions on which to exercise their generous and disinterested valour.

3. The courtesy, affability, and gallantry, for which these adventurers were so famous, are but the natural effects and consequences of their situation. For the castles of the barons were the courts of these little sovereigns, as well as their fortresses: the resort of their vassals thither, in honour of their chiefs, and for their own proper security, would make that civility and politeness which is seen at courts, and insensibly prevails there, a predominant part in the character of these assemblies. Further, the free commerce of the ladies, in these knots and circles of the great, would operate so far on the sturdiest knights as to give birth to the attentions of gallantry.

4. It only remains to account for that character of religion, which was so deeply imprinted on the minds of these knights, and was essential to their institution. Two reasons are assigned for this singularity. First, the superstition of the times, which was so great, that no institution of a public nature could have found credit that was not consecrated by churchmen and interwoven with religion. Secondly, the condition of the Christian world; which had but just recovered a breath-

ing time from the brutal ravages of the Saracen armies. The remembrance of what they had lately suffered from these enemies of their faith, made it natural and even necessary to engage a new military order on the side of religion. And here, by the way, the reason appears why the Spaniards, of all the Europeans, were furthest gone in every characteristic madness of true chivalry. Their fanaticism in every way was especially inflamed and kept alive by the memory and neighbourhood of their infidel invaders.

Such was the state of things in the western world, when the crusades to the holy land were set on foot. Whence we see how well prepared the minds of men were for engaging in that enterprise.

THERE is a remarkable correspondence between the manners of the old heroic times, as painted by their great romancer Homer, and those which are represented to us in the modern books of knight-errantry. A fact of which no good account can be given, but by another not less certain; that the political states of Greece, in the earliest periods of its story, was similar, in many respects, to that of Europe, as broken by the feudal system, into an infinite number of petty independent governments.

Some obvious circumstances of agreement between the heroic and Gothic manners may be worth putting down.

1. The military enthusiasm of the barons, is but of a piece with the fanaticism of the heroes. Hence the same particularity of description in the accounts of battles, wounds, deaths, in the Greek poet, as in the Gothic romancers. Hence that minute curiosity in the display of their dresses, arms, accoutrements. The minds of all men being occupied with warlike images and ideas, were much gratified by those details, which appear cold and uninteresting to modern readers.

We hear much of knights-errant encountering giants, and quelling savages, in books of chivalry. These giants were oppressive feudal lords, and every lord was to be met with, like the giant, in his strong-hold or castle. Their dependents of a lower form, who imitated the violence of their superiors, and had not their castles but lurking places, were the savages of romance. The greater lord was called a giant for his power; the less, a savage, for his brutality.

- Another terror of the Gothic ages, was monsters, dragons, and serpents. Their stories were received in those days for several reasons: 1. From the vulgar belief of enchantments: 2. From their being reported on the faith of eastern tradition, by adventurers from the holy land: 3. In still later times from the strange things told and believed on the discovery of the new world.

In all these respects, Greek antiquity resembles the Gothic. For what are Homer's *Læstrigons* and *Cyclops*, but bands of lawless savages, with each of them a giant of enormous size at their head? And what are the Grecian *Bacchus*, *Hercules*, and *Theſeus*, but knights-errant, the exact counterparts of Sir Launcelot, and Amadis de Gaul?

3. The oppressions which it was the glory of the knights to avenge, were frequently carried on, as we are told, by the *charms and enchantments of women*. These charms, we may suppose, are often metapho-

Chivalry.

The resemblance between the heroic and Gothic manners.

rical;

Chivalry. rical ; as expressing only the blandishments of the sex. Sometimes they are taken to be real, the ignorance of those ages acquiescing in such conceits. And are not these stories matched by those of Calypso and Circe, the enchantresses of the Greek Poet ?

4. Robbery and Piracy were honourable in both : so far were they from reflecting any discredit on the ancient or modern *redressers of wrongs*. What account can be given of this, but that, in the feudal times, and in the early days of Greece, when government was weak, and unable to redress the injuries of petty sovereigns, it would be glorious for private adventurers to undertake this work ; and, if they could accomplish it in no other way, to pay them in kind by downright plunder and rapine ?

5. Balthard was in credit with both. They were extremely watchful over the chastity of their own women ; but such as they could seize upon in the enemies quarter, were lawful prize. Or if, at any time, they transgressed in this sort at home, the fault was covered by an ingenious fiction. The offspring was reputed divine. Their greatest heroes were the fruit of goddesses approached by mortals ; just as we hear of the doughtiest knights being born of fairies.

6. With the greatest fierceness and savageness of character, the utmost generosity, hospitality, and courtesy, was imputed to the heroic ages. Achilles was at once the most relentless, vindictive, implacable, and the friendliest of men. We have the very same representation in the Gothic romances. As in those lawless times, dangers and distresses of all kinds abounded, there would be the same demand for compassion, gentleness, and generous attachments to the unfortunate, those especially of their own clan, as of resentment, rage, and animosity against their enemies.

7. Again, the martial games celebrated in ancient Greece, on great and solemn occasions, had the same origin and the same purpose as the tournaments of the Gothic warriors.

8. Lastly, the passions for adventures so natural in their situation, would be as naturally attended with the love of praise and glory. Hence the same encouragement, in the old Greek and Gothic times, to page-yrists and poets. In the affairs of religion and gallantry, indeed, the resemblance between the hero and the knight is not so striking. But the religious character of the knight was an accident of the times, and no proper effect of his civil condition. And that his devotion for the fair sex should so far surpass that of the hero, is a confirmation of the system here advanced. For the consideration had of the females in the feudal constitution, will of itself account for this difference. It made them capable of succeeding to fiefs, as well as the men. And does not one see, on the instant, what respect and dependence this privilege would draw upon them ?

It was of mighty consequence who should obtain the favour of a rich heiress. And though, in the strict feudal times, she was supposed to be in the power and at the disposal of her superior lord, yet this rigid state of things did not last long. Hence we find some distressed damsel was the spring and mover of every knight's adventure. She was to be rescued by his arms, or won by the fame and admiration of his prow-

els. The plain meaning of all which was this : That as, in these turbulent times, a protector was necessary to the weakness of the sex, so the courteous and valorous knight was to approve himself fully qualified for that purpose.

It may be observed, that the two poems of Homer were intended to expose the mischiefs and inconveniences arising from the political state of Old Greece : the *Iliad*, the dissensions that naturally spring up among independent chiefs ; and the *Odyssey*, the influence of their greater subjects, more especially when unrestrained by the presence of their sovereign. And can any thing more exactly resemble the condition of the feudal times, when, on occasion of any great enterprise, as that of the crusades, the designs of the confederate Christian states were perpetually frustrated, or interrupted at least, by the dissensions of their leaders ; and their affairs at home, as perpetually distressed and disordered by the rebellious usurpations of their greater vassals ? Jerusalem was to the European, what Troy had been to the Grecian princes.

Court of CHIVALRY, a court formerly held before the lord high constable and earl marshal of England jointly, and having both civil and criminal jurisdiction : but since the attainder of Stafford duke of Buckingham under Henry VIII. and the consequent extinguishment of the office of lord high constable, it hath usually, with respect to civil matters, been heard before the earl marshal only. This court by stat. 13. Ric. II. c. 2. hath cognizance of contracts and other matters, touching deeds of arms and war, as well out of the realm as in it. And from its sentences lies an immediate appeal to the king in person. This court was in great reputation in the times of pure chivalry, and afterwards during the English connexions with the continent, by the territories which their princes held in France : but is now grown almost entirely out of use, on account of the feebleness of its jurisdiction, and want of power to enforce its judgments ; as it can neither fine nor imprison, not being a court of record.

1. The *civil* jurisdiction of this court of chivalry, is principally in two points ; the redressing injuries of honour ; and correcting encroachments in matters of coat-armour, precedence, and other distinctions of families. As a court of honour, it is to give satisfaction to all such as are aggrieved in that point ; a point of a nature so nice and delicate, that its wrongs and injuries escape the notice of the common law, and yet are fit to be redressed somewhere. Such, for instance, as calling a man a *coward*, or giving him the lie ; for which, as they are productive of no immediate damage to his person or property, no action will lie in the courts at Westminster : and yet they are such injuries as will prompt every man of spirit to demand some honourable amends ; which, by the ancient law of the land, was given in the court of chivalry. But modern resolutions have determined, that how much soever a jurisdiction may be expedient, yet no action for words will at present lie therein. And it hath always been most clearly holden, that as this court cannot meddle with any thing determinable by common law, it therefore can give no pecuniary satisfaction or damages ; in as much as the quantity and determination

Chivalry
Chium.

determination thereof is ever of common law cognizance. And therefore this court of chivalry can at most order reparation in point of honour; as, to compel the defendant *mendacium sibi ipsi imponere*, or to take the lie that he has given upon himself, or to make such other submission as the laws of honour may require. As to the other point of its civil jurisdiction, the redressing of usurpations and encroachments in matters of heraldry and coat-armour; it is the business of this court, according to Sir Matthew Hale, to adjust the right and armorial ensigns, bearings, crests, supporters, pennons, &c.; and also rights of places or precedence, where the king's patent or act of parliament, which cannot be over-ruled by this court, have not already determined it. The proceedings of this court are by petition in a summary way: and the trial not by a jury of twelve men, but by witnesses, or by combat. But, as it cannot imprison, not being a court of record; and as, by the resolutions of the superior courts, it is now confined to so narrow and restrained a jurisdiction; it has fallen into contempt. The marshalling of coat-armour, which was formerly the pride and study of all the best families in the kingdom, is now greatly disregarded; and has fallen into the hands of certain officers and attendants upon this court, called *heralds*, who consider it only as a matter of lucre, and not of justice: whereby such falsity and confusion have crept into their records, (which ought to be the standing evidence of families, descents, and coat-armour), that though formerly some credit has been paid to their testimony, now, even their common seal will not be received as evidence in any court of justice in the kingdom. But their original visitation books, compiled when progresses were solemnly and regularly made into every part of the kingdom, to inquire into the state of families, and to register such marriages and descents as were verified to them upon oath, are allowed to be good evidence of pedigrees.

2. As a criminal court, when held before the lord high constable of England jointly with the earl Marshal, it had jurisdiction over pleas of life and member, arising in matters of arms and deeds of war, as well out of the realm as within it. But the criminal, as well as civil part of its authority, is fallen into entire disuse: there having been no permanent high constable of England, (but only *pro hac vice*, at coronations and the like), since the attainder and execution of Stafford duke of Buckingham, in the 13th year of Henry VIII.; the authority and charge, both in war and peace, being deemed too ample for a subject; so ample, that when the chief justice Fineux was asked by king Henry VIII. how far they extended? he declined answering; and said, the decision of that question belonged to the law of arms, and not to the law of England.

CHIVES, in botany, are slender thread-like substances, generally placed within the blossom, and surrounding the POINTALS. They are formed of the woody substance of the plant.

CHIUM MARMOR, in the natural history of the ancients, the name of a black marble, called also the *Lapis obsidianus*. It is very hard, and of a fine black; and, beside the many uses which the ancients put it to,

is well known among our goldsmiths by the name of the touch-stone; most of them being furnished with nothing better for that purpose than a piece of this: though the basalt, which might be had plentifully enough, is greatly preferable for those uses; any black marble, however, that is tolerably hard, will do. There is a very fine and elegantly smooth marble, of a compact texture, and fine glossy black, but shewing no glittering particles when fresh broken, as most of the black marbles do. It is extremely hard, and cuts with difficulty, but is capable of the highest polish of any marble. The ancients had it from Ethiopia and the island of Chios; we have it from Italy.

CHIUM VINUM, Chian wine, or wine of the growth of the island of Chios, now Scio, is commended by Dioscorides, as affording good nourishment, fit to drink, less disposed to intoxicate, endued with the virtue of restraining fluxions, and a proper ingredient in ophthalmic medicines. Hence Scribonius Largus directs the dry ingredients in collyria for the eyes to be made up with Chian wine.

CHLAMYS, in antiquity, a military habit worn by the ancients over the Tunica. It belonged to the patricians; and was the same in the time of war, that the toga was in the time of peace. This sort of gown was called *palla*, from the rich embroidery with figures in Phrygian work; and *purpurea*, because the ground-work was purple. The chlamydes of the emperors were all purple, adorned with a golden and embroidered border.

CHLOROSIS, in Medicine, a disease, commonly called the *green-sickness*, incident to young girls. See (the ENIGMA subjoined to) MEDICINE.

CHOCOLATE, in commerce, a kind of paste, or cake, prepared of certain ingredients, the basis of which is cacao. See CACAO.

The Indians, in their first making of chocolate, used to roast the cacao in earthen pots; and having afterwards cleared it of the husks, and bruised it between two stones, they made it into cakes with their hands. The Spaniards improved this method: when the cacao is properly roasted, and well cleaned, they pound it in a mortar, to reduce it into a coarse mass, which they afterwards grind on a stone till it be of the utmost fineness: the paste being sufficiently ground, is put quite hot into tin moulds, in which it coagels in a very little time. The form of these moulds is arbitrary: the cylindrical ones, holding two or three pounds, are the most proper; because the bigger the cakes are, the longer they will keep. Observe, that these cakes are very liable to take any good or bad scent, and therefore they must be carefully wrapt up in paper, and kept in a dry place. Complaints are made, that the Spaniards mix with the cacao nuts too great a quantity of cloves and cinnamon, besides other drugs without number, as musk, ambergrease, &c. The grocers of Paris use few or none of these ingredients: they only chuse the best nuts, which are called *caracas*, from the place from whence they are brought; and with these they mix a very small quantity of cinnamon, the sweetest vanilla, and the finest sugar, but very seldom any cloves. In England, the chocolate is made of the simple cacao, excepting that sometimes sugar and sometimes vanilla is added.

Chord.

Chocolate ready made, and cacao paste, are prohibited to be imported from any part beyond the seas. If made and sold in Great Britain, it pays inland-duty 1 s. 6 d. *per lb.* avoidupoise: it must be inclosed in papers containing one pound each, and produced at the excise-office to be stamped. Upon three days notice given to the officer of excise, private families may make chocolate for their own use, provided no less than half an hundred weight of nuts be made at one time.

The chocolate made in Portugal and Spain is not near so well prepared as the English; depending perhaps on the machine employed there, *viz.* the double cylinder, which seems very well calculated for exact triture. If perfectly prepared, no oil appears on the solution. London chocolate gives up no oil like the foreign; and it also may, in some measure, depend on the thickness of the preparation. The solution requires more care than is commonly imagined. It is proper to break it down, and dissolve it thoroughly in cold water by milling it with the chocolate stick. If heat is applied, it should be done slowly: for, if suddenly, the heat will not only coagulate it, but separate the oil; and therefore much boiling after it is dissolved, is hurtful. Chocolate is commonly required by people of weak stomachs; but often rejected for want of proper preparation. When properly prepared, it is easily dissolved; and an excellent food where a liquid nutrient vegetable one is required, and is less flatulent than any of the farinacea.

CHOCOLATE-*Nut Tree*. See CACAO.

CHOENIX, *γωνίς*, an ancient dry measure, containing the 48th part of a *medimnus*, or six bushels.

CHOIR, that part of the church or cathedral where choiristers sing divine service; it is separated from the chancel where the communion is celebrated, and also from the nave of the church where the people are placed: the patron is said to be obliged to repair the choir of the church. It was in the time of Constantine that the choir was separated from the nave. In the twelfth century, they began to inclose it with walls; but the ancient balustrades have been since restored, out of a view to the beauty of architecture.

CHOIR, in nunneries, is a large hall adjoining to the body of the church, separated by a grate, where the nuns sing the office.

CHOISI (Francis Timoleon de), dean of the cathedral of Bayeux, and one of the forty of the French academy, was born at Paris in 1644. In 1685, he was sent with the chevalier de Chaumont to the king of Siam, and was ordained priest in the Indies by the apostolical vicar. He wrote a great number of works, in a polite, florid, and easy style; the principal of which are, 1. Four dialogues on the Immortality of the soul, &c. 2. Account of a voyage to Siam. 3. An Ecclesiastical History, in 11 vols, 4^{to}. 4. Life of David, with an interpretation of the Psalms. 5. Life of Solomon, &c. He died at Paris in 1724.

CHOLEDOCHUS, in ANATOMY. See there, n^o 358.

CHOLER. See BILE.

CHOLERA MORBUS, a sudden eruption or overflowing of the bile or bilious matters both upwards and downwards. See (the *Index* subjoined to) MEDICINE.

CHONDROPTERYGII, in ichthyology, a term

formerly applied to the order of fishes now called *amphibia nantes* by Linnaeus. See AMPHIBIA.

CHOP-CHURCH, or CHURCH-CHOPPER, a name, or rather nick-name, given to parsons who make a practice of exchanging benefices. See PERMUTATION.

Chop-church occurs in an ancient statute as a lawful trade or occupation; and some of the judges say it was a good addition. Brook holds that it was no occupation, but a thing permissible by law.

CHOPIN, or CHOPINE, a liquid measure used both in Scotland and France, and equal to half their pint. See PINT and MEASURE.

CHOPIN (Rene), a famous civilian born at Bailleul in Anjou in 1537. He was advocate in the parliament of Paris, where he pleaded for a long time with great reputation. He at last shut himself up in his closet; and composed many works, which have been collected together, and printed in 6 vols, folio. He died at Paris in 1606.

CHORASSAN, or KHORASSAN, a province of Persia adjoining to Ubec Tartary. This was the ancient Bactria, and the birth-place of Kouli Khan.

CHORD, or CORD, primarily denotes a slender rope or cordage*. The word is formed of the Latin, *chorda*, and that from the Greek, χορδή, a gut, *dege*. * See COR- whereof strings may be made.

CHORD, in geometry, a right line drawn from one part of an arch of a circle to another. Hence,

CHORD of an Arch, is a right line joining the extremes of that arch.

CHORD, in music, the union of two or more sounds uttered at the same time, and forming together an entire harmony.

The natural harmony produced by the resonance of a sounding body, is composed of three different sounds, without reckoning their octaves; which form among themselves the most agreeable and perfect chord that can possibly be heard: for which reason they are called, on account of their excellence, *perfect chords*. Hence, in order to render that harmony complete, it is necessary that each chord should at least consist of three sounds. The trio is likewise found by musicians to include the perfection of harmony; whether because in this all the chords, and each in its full perfection, are used; or, because upon such occasions as render it improper to use them all, and each in its integrity, arts have been successfully practised to deceive the ear, and to give it contrary persuasion, by deluding it with the principal sounds of each chord, in such a manner as to render it forgetful of the other sounds necessary to their completion. Yet the octave of the principal sound produces new relations, and new consonances, by the completion of the intervals: they commonly add this octave, to have the assen- sible of all the consonances in one and the same chord; (see CONSONANCE.) Moreover, the addition of the dissonance, (see DISCORD,) producing a fourth sound superadded to the perfect chord, it becomes indispensibly necessary, if we would render the chord full, that we should include a fourth part to express this dissonance. Thus, the series of chords can neither be complete nor connected but by means of four parts.

Chords are divided into perfect and imperfect. The perfect chord is that which we have lately described; which.

Chord.

which is composed of the fundamental sound below, of its third, its fifth, and its octave : they are likewise subdivided into major and minor, according as the thirds which enter into their composition are flat or sharp : (See INTERVAL.) Some authors likewise give the name of *perfect* to all chords, even to dissonances, whose fundamental sounds are below. *Imperfect chords* are those in which the fifth, instead of the fifth, prevails, and in general all those whose lowest are not their fundamental sounds. These denominations, which had been given before the fundamental basis was known, are now most unhappily applied : those of chords *direct* and *reversed*, are much more suitable in the same sense. (See the account of *INVERTED Chords*).

Chords are once more divided into consonances and dissonances. The chords denominated *consonances*, are the perfect chord, and its derivatives : every other chord is a *dissonance*.

A table of both, according to the system of M. Rameau, may be seen in Roulleau's Musical Dictionary, vol. I. p. 27.

After the table to which our readers have been remitted, at Roulleau adds the following observations, which are at the same time so just and so important, that we should be very sorry if they escape the reader's attention.

At the words *harmony, fundamental basis, composition*, &c. he promises to treat concerning the manner of using all the chords to form regular harmony ; and only adds, in this place, the subsequent reflections.

1. It is a capital error to imagine, that the methods of inverting the same chord are in all cases equally eligible for the harmony, and for the expression. There is not one of these different arrangements, but has its proper character. Every one feels the contrast between the softness of the false fifth, and the grating sound of the tritone, though the one of these intervals is produced by a method of inverting the other. With the seventh diminished, and the second redundant, the case is the same with the interval of the second in general use, and the seventh. Who does not feel how much more vocal and sonorous the fifth appears when compared with the fourth ? The *chord* of the great sixth, and that of the lesser sixth minor, are two forms of the same fundamental *chord* : but how much less is the one harmonious than the other ? On the contrary, the *chord* of the lesser sixth major is much more pleasing and cheerful than that of the false fifth ? And only to mention the most simple of all *chords*, reflect on the majesty of the perfect chord, the sweetness of that which is called the chord of the sixth, and the insipidity of that which is composed of a sixth and a fourth ; all of them, however, composed of the same sounds. In general, the redundant intervals, the sharps in the higher part, are proper by their severity to express violent emotions of mind, such as anger and the rougher passions. On the contrary, flats in the higher parts, and diminished intervals, form a plaintive harmony, which melts the heart. There are a multitude of similar observations, of which when a musician knows how to avail himself, he may command at will the affections of those who hear him.

Chord
1
Chorion.

2. The choice of simple intervals is scarcely of less importance than that of the *chords*, with regard to the stations in which they ought to be placed. It is, for instance, in the lower parts that the fifth and octave should be used in preference ; in the upper parts, the third and sixth are more proper. If you transpose this order, the harmony will be ruined even though the same *chords* are preserved.

3. In a word, the *chords* are rendered still more harmonious, by being approximated and only divided by the smallest practicable intervals, which are more suitable to the capacity of the ear than such as are remote. This is what we call *contracting* the harmony, an art which few composers have skill and abilities enough to put in practice. The limits in the natural compass of voices, afford an additional reason for lessening the distance of the intervals, which compose the harmony of the chorus, as much as possible. We may affirm, that a chorus in improperly composed, when the distance between the *chords* increases ; when those who perform the different parts are obliged to scream ; when the voices rise above their natural extent, and are so remotely distant one from the other that the perception of harmonical relations between them is lost.

We say likewise, that an instrument is in *concord*, when the intervals between its fixed sounds are what they ought to be ; we say in this sense, that the *chords* of an instrument are true or false, that it preserves or does not preserve its *chords*. The same form of speaking is used for two voices which sing together, or for two sounds which are heard at the same time, whether in union or in parts.

CHORDS, or Chords, of Musical Instruments, are strings, by the vibration of which the sensation of sound is excited, and by the divisions of which the several degrees of tone are determined.

CHORDEE, in medicine and surgery, a symptom attending a gonorrhœa, consisting in a violent pain under the frenum, and along the duct of the urethra, during the erection of the penis, which is incurved downwards. These erections are frequent and involuntary.

CHOREA SANCTI VITI. See *VITUS's Dance*.

CHOREPISCOPUS, or COUNTRY-BISHOP, an assistant to a bishop, first introduced into the church when the dioceses became enlarged by the conversion of the Pagans in the country and villages at a distance from the mother-church.

CHOREPISCOPUS is also the name of a dignity in some cathedrals in Germany, signifying the same with chori-episcopus, or bishop of the choir. The first chanter in the church of Cologne is called chori-episcopus.

CHOREUS, *Xopeus*, a foot in the ancient poetry, more commonly called *trocheus*. See *TROCHEE*.

CHORIAMBUS, in ancient poetry, a foot consisting of four syllables, whereof the first and last are long, and the two middle ones are short ; or, which is the same thing, it is made up of a trocheus and iambus : such is the word *nobilitas*.

CHORION, in anatomy, the exterior membrane which invests the fœtus in the uterus. See *FŒTUS*.

CHOROBATA, or CHOROBATES, a kind of water

ter

ter level among the ancients, of the figure of the letter T, according to Vitruvius's description.

CHOROGRAPHY, the art of making a map of some country or province.

Chorography differs from geography, as the description of a particular country does from that of the whole earth; and from topography, as the description of a country differs from that of a town or district. See the articles **GEOGRAPHY**, **TOPOGRAPHY**, and **MAP**.

CHORUS, in dramatic poetry, one or more persons present on the stage during the representation, and supposed to be by-standers without any share in the action.

Tragedy in its origin was no more than a single chorus, who trod the stage alone, and without any actors, singing dithyrambs or hymns in honour of Bacchus. Thespis, to relieve the chorus, added an actor, who rehearsed the adventures of some of their heroes; and Æschylus, finding a single person too dry an entertainment, added a second, at the same time reducing the singing of the chorus, to make more room for the recitation. But when once tragedy began to be formed, the recitative, which at first was intended only as an accessory part to give the chorus a breathing time, became a principal part of the tragedy. At length, however, the chorus became inserted and incorporated into the action: sometimes it was to speak; and then their chief, whom they called *corryphæus*, spoke in behalf of the rest: the singing was performed by the whole company; so that when the *corryphæus* struck into a song, the chorus immediately joined him.

The chorus sometimes also joined the actors in the course of the representation, with their plaints and lamentations on account of any unhappy accidents that befel them: but the proper function, and that for which it seemed chiefly retained, was to shew the intervals of the acts: while the actors were behind the scenes, the chorus engaged the spectators; their songs usually turned on what was exhibited, and were not to contain any thing but what was suited to the subject, and had a natural connection with it; so that the chorus concurred with the actors for advancing the action. In the modern tragedies the chorus is laid aside, and the fiddles supply its place. Mr Dacier looks on this retrenchment as of ill consequence, and thinks it robs tragedy of a great part of its lustre; he therefore judges it necessary to re-establish it, not only on account of the regularity of the piece, but also to correct, by prudent and virtuous reflections, any extravagances that might fall from the mouths of the actors when under any violent passion.

Mr Dacier observed also, that there was a chorus, or *grex*, in the ancient comedy: but this is suppressed in the new comedy, because it was used to reprove vices by attacking particular persons; as the chorus of the tragedy was laid aside to give the greater probability to those kinds of intrigue which require secrecy.

CHORUS, in music, is when, at certain periods of a song, the whole company are to join the finger in repeating certain complets or verses.

CHOSE, (*Fr.*) "a thing;" used in the common law

VOL. III.

with divers epithets; as *chofe local*, *chofe transitory*, and *chofe in action*.

Chofe local is such a thing as is annexed to a place, as a mill and the like; *chofe transitory* is that thing which is moveable, and may be taken away, or carried from place to place; and *chofe in action* is a thing incorporeal, and only a *right*, as an obligation for debt, annuity, &c. And generally all canes of suit for any debt, duty, or wrong, are to be accounted *chofes in action*: and it seems, *chofe in action* may be also called *chofe in suspense*; because it hath no real existence or being, nor can properly be said to be in our possession.

CHOSROES I. the Great, king of Persia, after his father Cabades, *A. D.* 532. He made peace with the Romans; but broke it the third year, and forced Justinian to a disadvantageous peace. Afterwards, he was so swelled with his victories, as to bid the emperor's ambassador follow him for audience to Ctesarea: but Tiberius sent an army under Justinian; who made himself master of the country, and put Chosroes to death in 566.

CHOSROES II. His subjects put his father Hormisdas in prison, and the son upon the throne of Persia. He used his father tenderly at first; but afterwards caused him to be put to death. This, together with his killing some of the nobility, obliged him to fly: he gave his horse the bridle, which carried him into a town of the Romans, where Mauricius the emperor received him kindly, and sent an army under Narfes, which set him again upon the throne. He took Jerusalem; after this he made himself master of Libya and Egypt, and carried Carthage. Heraclius sued for peace; which was offered him on condition, *That he and his subjects should deny Jesus Christ*: Hereupon Heraclius attacked him with success, and put him to flight. His own son pursued him, and he was starved in prison in 627.

CHOUGH, in ornithology, the trivial name of a species of *Corvus*.

CHOUS, in the eastern military orders, the title of the messengers of the divan of janifaries. There are several degrees of honour in this post. When a person is first advanced to it, he is called a *cuchuk*, or little *chous*; after this he is advanced to be the *alby chous*; that is, the messenger of ceremonies; and from this, having passed through the office of *petelma*, or procurator of the effects of the body, he is advanced to be the *bas chous*.

CHREMNITZ, the principal of the nine-towns in Upper Hungary, situated about 68 miles north-east of Presburg, and subject to the house of Austria. *E. Long.* 19°. and *N. Lat.* 48. 45.

CHRISM, oil consecrated by the bishop, and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction.

CHRIST. See **CHRISTIANITY** and **MESSIAH**.
Order of CHRIST, a military order, founded by Dionysius I. king of Portugal, to animate his nobles against the Moors.—The arms of this order are gules, patriarchal cross, charged with another cross argent: they had their residence at first at Castromarin; afterwards they removed to the city of Thomar, as being nearer to the Moors of Andalusia and Estremadura.

Christ
|
Christianity

CHRIST is also the name of a military order in Livonia, instituted in 1205 by Albert bishop of Riga. The end of this institution was to defend the new Christians, who were converted every day in Livonia, but were persecuted by the heathens. They wore on their cloaks a sword with a cross over it, whence they were also denominated "brothers of the sword."

CHRIST-BURGH, a town of Poland, near the lake Draupen, and about three Polish miles from Marienburg.

CHRIST-CHURCH, a borough-town of Hampshire, 30 miles south-west of Winchester, near the sea-coast: W. Long. 2°. N. Lat. 50. 40. It sends two members to parliament.

CHRIST-THORN, in botany. See RHAMNUS.

Most CHRISTIAN KING, one of the titles of the king of France.

The French antiquaries trace the origin of this appellation up to Gregory the Great, who, writing a letter to Charles Martel, occasionally gave him that title, which his successors have since retained.

CHRISTIAN Religion, that instituted by Jesus Christ. See CHRISTIANITY.

1
Origin of
the word.

CHRISTIANITY, the religion of Christians. The word is analogically derived, as other abstracts from their concret, from the adjective *Christian*. This again is derived from the name *ΧΡΙΣΤΟΣ*, *Christus*, from the word *χρίω*, *I anoint*. Christ is called the *anointed*, from a custom which extensively prevailed in antiquity, and was originally said to be of divine institution, of anointing persons in the sacerdotal or regal character, as a public signal of their consecration to their important offices, and as a testimony that heaven itself was the guarantee of that relation which then commenced between the persons thus consecrated and their subordinates.

2
By what
name the
apostles
were first
distinguish-
ed.

The disciples of Jesus, after the death of their teacher, had for some time been called *Nazarenes*, from Nazareth in Galilee where he dwelt; which afterwards became the designation of a particular sect. They, who adopted the principles, and professed the religion which he taught, were first distinguished by the name of *Christians* at Antioch. That profession, and those doctrines, we now proceed to delineate with as much perspicuity as the limits of our plan will admit, yet with the conciseness which a work so multi-form and extensive requires.

3
Delineation
of Christi-
anity.

When a Christian is interrogated concerning the nature and foundation of his faith and practice, his ultimate reference, his last appeal, is to the facts, the doctrines, and the injunctions, contained in the books of the Old and New Testament. From these, therefore, and from these alone, must every fair account, or the materials of which it is composed, be extracted or deduced. Other formularies, or confessions of faith, may, according to the Christian, deserve more or less attention, as they are more or less immediately contained or implied in the scriptures. But whatever is not actually expressed in, or deduced by fair and necessary consequence from, these writings, must be regarded as merely human; and can have no other title to our assent and observation, than what they derive from their conformity with the scriptures, with the dic-

tates and feelings of a reformed and cultivated mind, or with those measures which are found expedient and useful in human life. But, as these books from whence the Christian investigates his principles of belief and rules of conduct, have been variously interpreted by different professors and commentators, these diversities have given birth to a multiplicity of different sects. It cannot, therefore, be expected, that any one who undertakes to give an account of Christianity, should comprehend all the writings and opinions which have been propagated and exhibited by historical, systematical, or polemical authors. These, if at all contained in such a work as this, should be ranged under their proper articles, whether scientific, controversial, or biographical. It is our present business, if possible, to confine ourselves to a detail of such facts and doctrines as, in the strict and primitive sense of the word, are *catholic*, or, in other expressions, to such as uniformly have been, and still are, recognized and admitted by the whole body of Christians.

4
Account of
Christiani-
ty, whence
deducible.

We have already said that these, or at least the greatest number of them, appeal to the scriptures of the Old and New Testament as the ultimate standard, the only infallible rule of faith and manners. If you ask them, by what authority these books claim an absolute right to determine the consciences and understandings of men with regard to what they should believe and what they should do? they will answer you, that all scripture, whether for doctrine, correction, or reproof, was given by immediate inspiration from God.

5
The nature
of its evi-
dences.

If again you interrogate them how those books, which they call Scripture, are authenticated? they reply, that the evidences by which the Old and New Testament are proved to be the Word of God, are either external or internal. The external may again be divided into direct or collateral. The direct evidences are such as arise from the nature, consistency, and probability, of the facts; and from the simplicity, uniformity, competency, and fidelity, of the testimonies by which they are supported. The collateral events, are either the same occurrences supported by Heathen testimonies, or others which concur with and corroborate the history of Christianity. Its internal evidences arise either from its exact conformity with the character of God, from its aptitude to the frame and circumstances of man, or from those supernatural convictions and assistances which are impressed on the mind by the immediate operation of the divine Spirit. These can only be mentioned in a cursory manner in a detail so concise as the present.

6
How Chri-
stianity is
supported
by facts.

Such facts as are related in the history of his religion, the Christian asserts to be not only consistent each with itself, but likewise one with another. Hence it is, that, by a series of antecedents and consequences, they corroborate each other, and form a chain which cannot be broken but by an absolute subversion of all historical authenticity. Nor is this all: for, according to him, the facts on which Christianity is founded, not only constitute a series of themselves, but are likewise in several periods the best resources for supplying the chasms in the history of our nature, and preserving the tenor of its annals entire. The facts themselves are either natural, or supernatural.

By

Christianity

By natural facts we mean such occurrences as happen or may happen from the various operations of mechanical powers, or from the interpolation of natural agents without higher assistants. Such are all the common occurrences of history, whether natural, biographical, or civil. By supernatural facts, we mean such as could not have been produced without the interposition of Deity, or at least of powers superior to the laws of mechanism or the agency of embodied spirits. Among these may be reckoned the immediate change of water into wine, the instantaneous cure of diseases without the intervention of medicine, the resuscitation of the dead, and others of the same kind. In this order of occurrences may likewise be numbered the exertions and exhibitions of prophetic power, where the persons by whom these extraordinary talents were displayed could neither by penetration nor conjecture unravel the mazes of futurity, and trace the events of which they spoke from their primary causes to their remote completions. So that they must have been the passive organs of some superior Being to whom the whole concatenation of causes and effects which operate from the origin to the consummation of nature, was obvious at a glance of thought.

7
Natural facts, what, and how conducive to the elucidation of history.

It has already been hinted, that the facts which we have called *natural*, not only agree with the analogy of human events, and corroborate each other, but in a great many emergencies nobly illustrate the history of human in general. For this a Christian might offer one instance, of which philosophy will not perhaps be able to produce any tolerable solution, without having recourse to the facts upon which Christianity is founded. For if mankind were originally descended from one pair alone, how should it have happened that long before the date of authentic history every nation had its own distinct language? Or if it be supposed, as some late philosophers have maintained, that man is an indigenous animal in every country; or, that he was originally produced in, and created for, each particular soil and climate which he inhabits; still it may be demanded, whence the prodigious multiplicity, the immense diversity, of languages? Is the language of every nation intuitive, or were they dictated by exigencies, and established by convention? If the last of these suppositions be true, what an immense period of time must have passed? How many revolutions of material and intellectual nature must have happened? What accessions of knowledge, refinement, civilization, must human intercourse have gained before the formation and establishment even of the most simple, imperfect, and barbarous language? Why is a period so vast, obliterated so entirely as to escape the retrospect of history, of tradition, and even of fable itself? Why was the acquisition and improvement of other arts so infinitely distant from that of language, that the era of the latter is entirely lost, whilst we can trace the former from their origin through the various gradations of their progress.

8
This obscurity inexplicable but by the Mosaic account.

These difficulties, inextricable by all the lights of history or philosophy, this more than Cimmerian darkness is immediately dissipated by the Mosaic account of the confusion of tongues; wisely intended to separate the tribes of men one from another, to replenish the surface of the globe, and to give its multiplied in-

habitants those opportunities of improvement which Christianity might be derived from experiment and industry, variously exerted, according to the different situations in which they were placed, and the different employments which these situations dictated. Thus the time of nature's existence is limited to a period within the ken of human intellect. Thus whatever has happened might have happened during the present mode of things; whereas, if we deduce the origin and diversity of language from a period so remotely distant as to be absolutely lost, and entirely detached from all the known occurrences and vicissitudes of time, we must admit the present forms and arrangements of things to have subsisted perhaps for a much longer duration than any mechanical philosopher will allow to be possible. Other instances equally pregnant with conviction might be multiplied; but, precluded by the limits of our plan, we proceed to a single observation upon the facts which have been termed supernatural.

Of those changes which happen in sensible objects, sensation alone can be judge. Reason has nothing to do in the matter. She may draw conclusions from the testimonies of sense, but can never refute them. If, therefore, our senses inform us that snow is white, in vain would the most learned and subtle philosopher endeavour to convince us that it was of a contrary colour. He might confound us, but never could persuade us. Such changes, therefore, as appear to happen in sensible objects, must either be real or fallacious. If real, the miracle is admitted; if fallacious, there must be a cause of deception equally unaccountable from the powers of nature, and therefore equally miraculous. If the veracity or competency of the witnesses be questioned, the Christian answers, that they must be competent, because the facts which they relate are not beyond their capacity to determine. They must likewise be faithful, because they had no secular motives for maintaining, but many for suppressing or disguising, what they testified. Now the Christian appeals to the whole series of history and experience, whether such a man is or can be found, as will offer a voluntary, solemn, and deliberate sacrifice of truth at the shrine of caprice. But such facts as after a long continuance of time have been found exactly agreeable to predictions formerly emitted, must fully persuade the fidelity of testimony, and infallibly prove, that the event was known to the Being by whom it was foretold. In vain has it been urged, that prophecies are ambiguous and equivocal. For though they may prefigure subordinate events, yet if the grand occurrences to which they ultimately relate, can alone fulfil them in their various circumstances, and in their utmost extent, it is plain, that the Being by whom they were revealed must have been actually present of those events, and must have had them in view when the predictions were uttered. For this see a learned and ingenious dissertation on the Credibility of Gospel-history, by Dr McKnight; where the evidences urged by the Christian in defence of his tenets, which appear detached and scattered through innumerable volumes, are assembled and arranged in such a manner as to derive strength and lustre from the method in which they are disposed, without diminishing the force of each in particular. Miracles, how conducive to prove the truth of Christianity.

10
Prophecy evident by its own nature independent of its vehicles.

Christianity works of Dr Hurd: consult likewise those of Newton, Sherlock, Chandler, &c. For the evidences of those preternatural facts which have been termed miracles, the reader may peruse a short but elegant and conclusive defence of these astonishing phenomena, in answer to Mr Hume, by the Rev. George Campbell, D. D.

11
Properties
common to
all religions.

It must be obvious to every reflecting mind, that whether we attempt to form the idea of any religion *a priori*, or contemplate those which have been already exhibited, certain facts, principles, or data, must be pre-established, from whence will result a particular frame of mind and course of action suitable to the character and dignity of that Being by whom the religion is enjoined, and adapted to the nature and situation of those agents who are commanded to observe it. Hence *Christianity* may be divided into *credenda* or doctrines, and *agenda* or precepts.

12
Christian
theology.

.. As the great foundation of his religion, therefore, the Christian believes the existence and government of one eternal and infinite Essence, which for ever retains in itself the cause of its own existence, and inherently possesses all those perfections which are compatible with its nature: such are, its almighty power, omniscient wisdom, infinite justice, boundless goodness, and universal presence. In this indivisible essence the Christian recognises three distinct subsistences, yet distinguished in such a manner as not to be incompatible with essential unity or simplicity of being. Nor is their essential union incompatible with their personal distinction. Each of them possesses the same nature and properties to the same extent. As, therefore, they are constituent of one God, if we may use the expression, there is none of them subordinate, none supreme. The only way by which the Christian can discriminate them, is by their various relations, properties, and offices. Thus the Father is said eternally to beget the Son, the Son to be eternally begotten of the Father, and the Holy Ghost eternally to proceed from both.

This infinite Being, though absolutely independent and for ever sufficient for his own beatitude, was graciously pleased to create an universe replete with inferior intelligences, who might for ever contemplate and enjoy his glory, participate his happiness, and imitate his perfections. But as freedom of will is essential to the nature of moral agents, that they may co-operate with God in their own improvement and happiness, so their natures and powers are necessarily limited, and by that constitution rendered peccable. This degeneracy first took place in a rank of intelligence superior to man. But guilt is never stationary. Impatient of itself, and cursed with its own feelings, it proceeds from bad to worse, whilst the poignancy of its torments increases with the number of its perpetrations. Such was the situation of Satan and his apostate angels. They attempted to transfer their turpitude and misery to man; and were, alas! but too successful. Hence the heterogeneous and irreconcilable principles which operate in his nature. Hence that inexplicable medley of wisdom and folly, of rectitude and error, of benevolence and malignity, of sincerity and fraud, exhibited through his whole conduct. Hence the darkness of his understanding, the depravity of his will, the pollution of his heart, the ir-

regularity of his affections, and the absolute subversion of his whole internal economy. These seeds of perdition soon ripened into overt acts of guilt and horror. All the hostilities of nature were confronted, and the whole sublunary creation became a theatre of disorder and mischief.

Here the Christian once more appeals to fact and experience. If these things are so; if *man* is the vessel of guilt and the victim of misery; he demands how this constitution of things can be accounted for? how can it be supposed, that a being so wicked and unhappy should be the production of an infinitely perfect Creator? He therefore insists, that human nature must have been disarranged and contaminated by some violent shock; and that, of consequence, without the light diffused over the face of things by Christianity, all nature must remain an inscrutable and inexplicable mystery.

To redress these evils, to re-establish the empire of virtue and happiness, to restore the nature of man to its primitive rectitude, to satisfy the remonstrances of infinite justice, to purify every original or contracted stain, to expiate the guilt and destroy the power of vice, the eternal Son of God, the second person of the sacred Trinity, the Logos or divine Word, the Redeemer or Saviour of the world, the Immanuel or God with us, from whom *Christianity* takes its name, and to whom it owes its origin, descended from the bosom of his Father; assumed the human nature; became the representative of man; endured a severe probation in that character; exhibited a pattern of perfect righteousness; and at last ratified his doctrine, and fully accomplished all the ends of his mission, by a cruel, unmerited, and ignominious death. Before he left this world, he delivered the doctrine of human salvation, and the rules of human conduct, to his apostles, whom he empowered to instruct the world in all that concerned their eternal felicity, and whom he invested with miraculous gifts to ascertain the reality of what they taught. To them he likewise promised another comforter, even the divine Spirit, who should relieve the darkness, console the woes, and purify the stains, of human nature. Having remained for a part of three days under the power of death, he arose again from the grave, discovered himself to his disciples, conversed with them for some time, then re-ascended to heaven; from whence the Christian expects him, according to his promise, to appear as the Sovereign Judge of the living and the dead, from whose awards there is no appeal, and by whose sentence the destiny of the pious and the wicked shall be eternally fixed.

Soon after his departure to the right hand of his Father, where, in his human nature, he sits supreme of all created beings, and invested with the absolute administration of heaven and earth, the Spirit of grace and consolation descended on his apostles with visible signatures of divine power and presence. Nor were his salutary operations confined to them, but extended to all the rational world, who did not by obstinate guilt repel his influences, and provoke him to withdraw them. These, indeed, were less conspicuous than at the glorious era when they were visibly exhibited in the persons of the apostles. But
though

Christianity though his energy is less observable, it is by no means less effectual to all the purposes of grace and mercy.

The Christian is convinced, that there is and shall continue to be a society upon earth, who worship God as revealed in Jesus Christ; who believe his doctrines; who observe his precepts; and who shall be saved by his death, and by the use of these external means of salvation which he hath appointed.

13
The external means of Christianity, what, and how promotive of their end.

These are few and simple. The sacraments of baptism and the eucharist, the interpretation and application of scripture, the habitual exercise of public and private devotion, are obviously calculated to diffuse and promote the interests of truth and virtue, by superinducing the salutary habits of faith, love, and repentance.

The Christian is firmly persuaded, that at the consummation of things, when the purposes of providence in the various revolutions of progressive nature are accomplished, the whole human race shall once more issue from their graves; some to immortal felicity, from the actual perception and enjoyment of their Creator's preference; others to everlasting shame and misery.

14
Christian morality.

The two grand principles of action, according to the Christian, are, The love of God, which is the sovereign passion in every perfect mind; and the love of man, which regulates our actions according to the various relations in which we stand, whether to communities or individuals. This sacred connection can never be totally extinguished by any temporary injury. It ought to subsist in some degree even amongst enemies. It requires that we should pardon the offences of others, as we expect pardon for our own; and that we should no further resist evil than is necessary for the preservation of personal rights and social happiness. It dictates every relative and reciprocal duty between parents and children, masters and servants, governors and subjects, friends and friends, men and men. Nor does it merely enjoin the observation of equity, but likewise inspires the most sublime and extensive charity, a boundless and disinterested effusion of tenderness for the whole species, which feels their distresses and operates for their relief and improvement. These celestial dispositions, and the different duties which are their natural exertions, are the various gradations by which the Christian hopes to attain the perfection of his nature and the most exquisite happiness of which it is susceptible.

15
This system, asserted by the Christian, superior in the excellence of its nature, and the evidence of its reality, to all others.

Such are the speculative, and such the practical principles of Christianity. From the former, its votaries contend, that the origin, economy, and revolutions of intelligent nature alone can be rationally explained. From the latter, they assert, that the nature of man, whether considered in its individual or social capacity, can alone be conducted to its highest perfection and happiness. With the determined Atheists, they scarcely desire to expostulate. For, according to them, philosophers who can deduce the origin and constitution of things from casual encounters or mechanical necessity, are capable of deducing any conclusion from any premises. Nor can a more glaring instance of absurdity be produced, than the idea of a contingent or self-originated universe. When Deists and other sectarians upbraid them with myste-

rious or incompatible principles, they without hesitation remit such cavillers to the creed of natural religion. They demand why any reasoner should refuse to believe three distinct subsistences in one indivisible essence, who admits that a being may be omnipresent without extension; or that he can impress motion upon other things, whilst he himself is necessarily immovable. They ask the sage, why it should be thought more extraordinary, that the Son of God should be sent to this world, that he should unite the human nature to his own, that he should suffer and die for the relief of his degenerate creatures, than that an existence whose felicity is eternal, inherent, and infinite, should have any motive for creating beings exterior to himself. Is it not, says the Christian, equally worthy of the divine interposition to restore order and happiness where they are lost, as to communicate them where they never have been? Is not infinite goodness equally conspicuous in relieving misery as in diffusing happiness? Is not the existence of what we call evil in the world, under the tuition of an infinitely perfect Being, as inscrutable as the means exhibited by Christianity for its abolition. Vicarious punishment, imputed guilt and righteousness, merit or demerit transferred, are certainly no less reconcilable to human reason, *a priori*, than the existence of vice and punishment in the productions of infinite wisdom, power, and goodness: particularly, when it is considered, that the virtues exerted and displayed by a perfect Being in a state of humiliation and suffering, must be meritorious, and may therefore be rewarded by the restored felicity of inferior creatures, in proportion to their glory and excellence; and that such merit may apply the blessings which it has deserved, in whatever manner, in whatever degree, and to whomsoever it pleases, without being under any necessity to violate the freedom of moral agents, in recalling them to the paths of virtue and happiness by a mechanical and irresistible force.

It will be granted to philosophy by the Christian, that as no theory of mechanical nature can be formed without presupposing sacred and established laws from which he ought rarely or never to deviate, so in fact she tenaciously pursues these general institutions, and from their constant observance result the order and regularity of things. But he cannot admit, that the important ends of moral and intellectual improvement may be uniformly obtained by the same means. He affirms, that if the hand of God should either remain always entirely invisible, or at least only perceptible in the operation of second causes, intelligent beings would be apt in the course of time to resolve the interpositions of Deity into the general laws of mechanism; to forget his connection with nature, and consequently their dependence upon him. Hence, according to the dictates of common-sense, and to the unanimous voice of every religion in every age or clime, for the purposes of wisdom and benevolence, God may not only control, but has actually controlled, the common course and general operations of nature. So that, as in the material world the law of *cause and effect* is generally and scrupulously observed for the purposes of natural subsistence and accommodation; thus suspenses and changes of that universal law are equally necessary for

16
Miraculous as possible, and perhaps as necessary as natural events.

the

Christianity the advancement of moral and intellectual perfection.

17 But the disciple of Jesus not only contends, that no system of religion has ever yet been exhibited so consistent with itself, so congruous to philosophy and the common sense of mankind, as Christianity. He likewise avers, that it is infinitely more productive of real and sensible consolation than any other religious or philosophical tenets, which have ever entered into the soul, or been applied to the heart of man. For what is death to that mind which considers eternity as the career of its existence? What are the frowns of fortune to him who claims an eternal world as his inheritance? What are the loss of friends to that heart which feels, with more than natural conviction, that it shall quickly rejoin them in a more tender, intimate, and permanent intercourse than any of which the present life is susceptible? What are the fluctuations and vicissitudes of external things to a mind which strongly and uniformly anticipates a state of endless and immutable felicity? What are mortifications, disappointments, and insults, to a spirit which is conscious of being the original offspring and adopted child of God; which knows that its omnipotent Father will, in proper time, effectually assert the dignity and privileges of its nature? In a word, as earth is but a speck of creation, as time is not an instant in proportion to eternity, such are the hopes and prospects of the Christian in comparison of every sublunary misfortune or difficulty. It is therefore, in his judgment, the eternal wonder of angels, and indelible opprobrium of man, that a religion so worthy of God, so suitable to the frame and circumstances of our nature, so consonant to all the dictates of reason, so friendly to the dignity and improvement of intelligent beings, pregnant with genuine comfort and delight, should be rejected and despised. Were there a possibility of suspense or hesitation between this and any other religion extant, he could freely trust the determination of a question so important to the candid decision of real virtue and impartial philosophy.

Thus have we given what we hope will be esteemed a genuine, though short, account of those principles of faith and rules of action which are received by the generality of Christians. Such points as are either disputable or have been controverted by different sects, we have industriously endeavoured to avoid. But every man who profoundly reflects will easily see, that this plan, in its full extent, was impracticable. A more minute detail of its origin, progress, and establishment, is given under the article MESSIAH.

CHRISTIANS, those who profess the religion of Christ. See CHRISTIANITY, and MESSIAH.

The first Christians distinguished themselves in the most remarkable manner by their conduct and their virtues. The faithful, whom the preaching of St Peter had converted, hearkened attentively to the exhortations of the Apostles, who failed not carefully to instruct them, as persons who were entering upon an entirely new life. They went every day to the temple with one heart and one mind, and continued in prayers; doing nothing different from the other Jews, because it was not yet time to separate from them. But they

made a still greater progress in virtue; for they sold all that they possessed, and distributed their goods in proportion to the wants of their brethren. They eat their meat with gladness and singleness of heart, praising God, and having favour with all the people. St Chrysostom, examining from what source the eminent virtue of the first Christians flowed, ascribes it principally to their divesting themselves of their possessions: "For (says that father) persons from whom all that they have is taken away are not subject to sin: where- as, whoever has large possessions wants not a devil or a tempter to draw him into hell by a thousand ways."

The Jews were the first, and the most inveterate enemies the Christians had. They put them to death as often as they had it in their power: and, when they revolted against the Romans in the time of the emperor Adrian, Barchochebas, the head of that revolt, employed against the Christians the most rigorous punishments, to compel them to blaspheme and renounce Jesus Christ. And we find that, even in the 3^d century, they endeavoured to get into their hands Christian women, in order to scourge and stone them in their synagogues. They cursed the Christians solemnly three times a day in their synagogues, and their rabbins would not suffer them to converse with Christians upon any occasion. Nor were they contented to hate and detest them: but they dispatched emissaries all over the world to defame the Christians, and spread all sorts of calumnies against them. They accused them, among other things, of worshipping the sun, and the head of an ass. They reproached them with idleness, and being an useless race of people. They charged them with treason, and endeavouring to erect a new monarchy against that of the Romans. They affirmed, that, in celebrating their mysteries, they used to kill a child, and eat its flesh. They accused them of the most shocking incests, of impudence, avarice, and sometimes of prodigality, and of intemperance in their feasts of charity. But the lives and behaviour of the first Christians were sufficient to refute all that was said against them, and evidently demonstrated, that these accusations were meer calumny, and the effect of inveterate malice.

Pliny the younger, who was governor of Pontus and Bithynia, between the years 103 and 105, gives a very particular account of the Christians in that province, in a letter which he wrote to the emperor Trajan, of which the following is an extract: "I take the liberty, Sir, to give you an account of every difficulty which arises to me. I have never been present at the examination of the Christians; for which reason I know not what questions have been put to them, nor in what manner they have been punished. My behaviour towards those who have been accused to me has been this: I have interrogated them, in order to know whether they were really Christians. When they have confessed it, I have repeated the same question two or three times, threatening them with death, if they did not renounce this religion. Those who have persisted in their confession, have been, by my order, led to punishment. I have even met with some Roman citizens guilty of this phrensy, whom, in regard

Christians.

"regard to their quality, I have set apart from the rest, in order to send them to Rome. These persons declare, that their whole crime, if they are guilty, consists in this; that, on certain days, they assemble before sun-rise, to sing alternately the praises of Christ, as of a God, and to oblige themselves, by the performance of their religious rites, not to be guilty of theft, or adultery, to observe inviolably their word, and to be true to their trust. This disposition has obliged me to endeavour to inform myself still farther of this matter, by putting to the torture two of their women-servants, whom they call *deaconesses*: but I could learn nothing more from them, than that the superstition of these people is as ridiculous, as their attachment to it is prodigious."

There is extant a justification, or rather panegyric, of the Christians, pronounced by the mouth of a Pagan prince. It is a letter of the emperor Antoninus, written in the year 152, in answer to the states of Asia, who had accused the Christians of being the cause of some earthquakes which had happened in that part of the world. The emperor advises them to "take care, lest, in torturing and punishing those, whom they accused of atheism, (*meaning the Christians*), they should render them more obstinate, instead of prevailing upon them to change their opinion; since their religion taught them to suffer with pleasure for the sake of God." As to the earthquakes that had happened, he puts them in mind, that "they themselves are always discouraged, and sink under such misfortunes; whereas the Christians never discovered more cheerfulness and confidence in God, than upon such occasions." He tells them, that "they pay no regard to religion, and neglect the worship of the eternal; and, because the Christians honour and adore him, therefore they are jealous of them, and persecute them even to death." He concludes: "many of the governors of provinces have formerly written to my father concerning them, and his answer always was, that they should not be molested or disturbed, provided they quietly submitted to the authority of the government. Many persons have likewise consulted me upon this affair, and I have returned the same answer to them all; namely, that, if any one accuses a Christian merely on account of his religion, the accused person shall be acquitted, and the accuser himself punished." This ordinance, according to Eusebius, was publicly fixed up at Ephesus, in an assembly of the states.

It is no difficult matter to discover the causes of the many persecutions, to which the Christians were exposed during the three first centuries. The purity of the Christian morality, directly opposite to the corruption of the Pagans, was doubtless one of the most powerful motives of the public aversion. To this may be added, the many calumnies unjustly spread about concerning them, by their enemies, particularly the Jews. And this occasioned so strong a prejudice against them, that the Pagans condemned them without inquiring into their doctrine, or permitting them to defend themselves. Besides, their worshipping Jesus Christ, as God, was contrary to one of the most ancient laws of the Roman empire, which expressly for-

bad the acknowledging of any god, which had not been approved by the senate.

But, notwithstanding the violent opposition made to the establishment of the Christian Religion, it gained ground daily, and very soon made a surprising progress in the Roman empire. In the 3^d century, there were Christians in the camp, in the senate, in the palace, in short every where, but in the temples, and the theatres: they filled the towns, the country, the islands. Men and women, of all ages and conditions, and even those of the first dignities embraced the faith; inasmuch that the Pagans complained, that the revenues of their temples were ruined. They were in such great numbers in the empire, that (as Tertullian expresses it) were they to have retired into another country, they would have left the Romans only a frightful solitude.

The primitive Christians were not only remarkable for the practice of every virtue: they were also very eminently distinguished by the many miraculous gifts, and graces, bestowed by God upon them. "Some of the Christians (says Irenæus) drive out devils, not in appearance only, but so as that they never return; whence it often happens, that those, who are possessed of evil spirits, embrace the faith, and are received into the Church. Others know what is to come, see visions, and deliver oracles as prophets. Others heal the sick by laying their hands on them, and restore them to perfect health: and we find some, who even raise the dead.—It is impossible to reckon up the gifts and graces, which the Church has received from God—what they have freely received they as freely bestow. They obtain these gifts by prayer alone, and invocation of the name of Jesus Christ, without any mixture of enchantment, or superstition."

We shall here subjoin the remarkable story attested by Pagan authors themselves, concerning the *Christian Legion* in the army of the emperor Marcus Aurelius. That prince, having led his forces against the Quadi, a people on the other side of the Danube, was surrounded and hemmed in by the enemy, in a disadvantageous place, and where they could find no water. The Romans were greatly embarrassed, and, being pressed by the enemy, were obliged to continue under arms, exposed to the violent heat of the sun, and almost dead with thirst; when, on a sudden, the clouds gathered, and the rain fell in great abundance. The soldiers received the water in their bucklers and helmets, and satisfied both their own thirst, and that of their horses. The enemy, presently after, attacked them; and so great was the advantage they had over them, that the Romans must have been overthrown, had not heaven again interposed by a violent storm of hail, mixed with lightning, which fell on the enemy, and obliged them to retreat. It was found afterwards, that one of the legions, which consisted of *Christians*, had, by their prayers, which they offered up on their knees before the battle, obtained this favour from heaven: and from this event that legion was named the *thundering Legion*. See, however, the criticism of Mr Moyle on this story, in his *Works*, vol. ii. p. 81—390. See also *Musheim's Church History*, vol. i. p. 124.

Such were the primitive Christians, whose religion

has

Christians
+
Christian-
stadt.

has by degrees spread itself over all parts of the world, though not with equal purity in all. And though, by the providence of God, Mohammedans and Idolaters have been suffered to possess themselves of those places in Greece, Asia, and Africa, where the Christian religion formerly most flourished; yet they are still such remains of the Christian religion among them, as to give them opportunity sufficient to be converted. For, in the dominions of the Turk in Europe, the Christians make two third parts at least of the inhabitants; and in Constantinople itself there are above twenty Christian churches, and above thirty in Thessalonica. Philadelphia, now called Ala-shahir, has no fewer than twelve Christian churches. The whole island of Chio is governed by Christians: and some islands of the Archipelago are inhabited only by Christians. In Africa, besides the Christians living in Egypt, and in the kingdom of Congo and Angola, the islands upon the western coasts are inhabited by Christians; and the vast kingdom of Abyssinia, supposed to be as big as Germany, France, Spain, and Italy, put together, is possessed by Christians. In Asia, most part of the empire of Russia, the countries of Circassia and Mingrelia, Georgia, and mount Libanus, are inhabited only by Christians. In America, it is notorious, that the Christians are very numerous, and spread over most parts of that vast continent.

CHRISTIANS of *St John*, a sect of Christians very numerous in Balfara and the neighbouring towns: they formerly inhabited along the river Jordan, where St John baptized, and it was from thence they had their name. They hold an anniversary feast of five days; during which they all go to the bishop, who baptizes them with the baptism of St John. Their baptism is also performed in rivers, and that only on Sundays: they have no notion of the third Person in the Trinity; nor have they any canonical book, but abundance full of charms, &c. Their bishoprics descend by inheritance, as our estates do, though they have the ceremony of an election.

CHRISTIANS of *St Thomas*, a sort of Christians in a peninsula of India, on this side of the gulf: they inhabit chiefly at Cranganor, and the neighbouring country: these admit of no images; and receive only the cross, to which they pay a great veneration: they affirm, that the souls of the saints do not see God till after the day of judgment: they acknowledge but three sacraments, *viz.* baptism, orders, and the eucharist: they make no use of holy oils in the administration of baptism; but, after the ceremony, anoint the infant with an unction composed of oil and walnuts, without any benediction. In the eucharist, they consecrate with little cakes made of oil and salt, and instead of wine make use of water in which raisins have been infused.

CHRISTIANA, a town of Norway, in the province of Aggerhuys, situated on a bay of the sea. E. Long. 10. 15. N. Lat. 59. 30.

CHRISTIANOPLE, a port-town of Sweden, situated on the Baltic sea, in the territory of Blecking, and province of South Gothland. E. Long. 15. 40. N. Lat. 57°.

CHRISTIANSTADT, a town of Sweden; situated on the river Helles, in the territory of Blecking, and

province of South Gothland. E. Long. 14. 40. N. Lat. 56. 30.

CHRISTINA, daughter of Gustavus Adolphus king of Sweden, was born in 1626; and succeeded to the crown in 1633, when only seven years of age. This princess discovered even in her infancy what she afterwards expressed in her memoirs, an invincible antipathy for the employments and conversation of women; and she had the natural awkwardness of a man, with respect to all the little works which generally fall to their share. She was, on the contrary, fond of violent exercises, and such amusements as consist in feats of strength and activity; she had also both ability and taste for abstracted speculations; and amused herself with language and the sciences, particularly that of legislature and government. She derived her knowledge of ancient history from its source; and Polybius and Thucydides were her favourite authors. As she was the sovereign of a powerful kingdom, it is not strange that almost all the princes in Europe aspired to her bed: Among others, were the Prince of Denmark, the Elector Palatine, the Elector of Brandenburg, the king of Spain, the king of the Romans, Don John of Austria, Sigismund of Rockocci, count and general of Cassovia; Stanislaus, king of Poland; John Cassimir, his brother; and Charles Gustavus, duke of Deux Ponts, of the Bavarian Palatinate family, son of her father the great Gustavus's sister, and consequently her first cousin. To this nobleman, as well as to all his competitors, she constantly refused her hand; but she caused him to be appointed her successor by the states. Political interests, differences of religion, and contrariety of manners, furnished Christina with pretences for rejecting all her suitors; but her true motives were the love of independence, and a strong aversion she had conceived, even in her infancy, from the marriage yoke. "Do not force me to marry, (said she to the states); for if I should have a son, it is not more probable that he should be an Augustus than a Nero."

An accident happened in the beginning of her reign which gave her a remarkable opportunity of displaying the strength and equanimity of her mind. As she was at the chapel of the castle of Stockholm, assisting at divine service with the principal lords of her court, a poor wretch, who was disordered in his mind, came to the place with a design to assassinate her. This man who was preceptor of the college, and in the full vigour of his age, chose, for the execution of his design, the moment in which the assembly was performing what in the Swedish church is called an *act of recollection*, a silent and separate act of devotion performed by each individual kneeling and hiding the face with the hand. Taking this opportunity, he rushed through the crowd, and mounted a ballustrade within which the queen was upon her knees: the baron Braki, chief justice of Sweden, was alarmed, and cried out; and the guards crossed their partisans, to prevent his coming further: but he struck them furiously on one side; leaped over the barrier; and, being then close to the queen, made a blow at her with a knife which he had concealed without a sheath in his sleeve. The queen avoided the blow, and pushed the captain of her guards, who instantly threw

Christina.

Christina. threw himself upon the assassin, and seized him by the hair. All this happened in less than a moment of time. The man was known to be mad, and therefore nobody supposed he had any accomplices: they therefore contented themselves with locking him up; and the queen returned to her devotion without the least emotion that could be perceived by the people, who were much more frightened than herself.

One of the great affairs that employed Christina while she was upon the throne, was the peace of Westphalia, in which many clashing interests were to be reconciled, and many claims to be ascertained. It was concluded in the month of October 1648. The success of the Swedish arms rendered Christina the arbitress of this treaty; at least as to the affairs of Sweden, to which this peace confirmed the possession of many important countries. No public event of importance took place during the rest of Christina's reign; for there were neither wars abroad, nor troubles at home. This quiet might be the effect of chance; but it might also be the effect of a good administration, and the great reputation of the queen; and the love her people had for her ought to lead us to this determination. Her reign was that of learning and genius. She drew about her, wherever she was, all the distinguished characters of her time: Grotius, Pascal, Bochart, Descartes, Gassendi, Saumaise, Naude, Vossius, Heinsius, Meibom, Scudery, Menage, Lucas, Holstenius, Lambecius, Bayle, madam Dacier, Filicaja, and many others. The arts never fail to immortalize the prince who protects them; and almost all these illustrious persons have celebrated Christina, either in poems, letters, or literary productions of some other kind, the greater part of which are now forgotten. They form, however, a general cry of praise, and a mass of testimonials which may be considered as a solid basis of reputation. Christina, however, may be justly reproached with want of taste, in not properly assigning the rank of all these persons, whose merits, though acknowledged, were yet unequal; particularly for not having been sufficiently sensible of the superiority of Descartes, whom she disgusted, and at last wholly neglected. The rapid fortune which the adventurer Michon, known by the name of *Bourdelot*, acquired by her countenance and liberality, was also a great scandal to literature. He had no pretensions to learning; and though sprightly, was yet indecent. He was brought to court by the learned Saumaise; and, for a time, drove literary merit entirely out of it, making learning the object of his ridicule, and exacting from Christina an exorbitant tribute to the weaknefs and inconstancy of her sex; for even Christina, with respect to this man, shewed herself to be weak and inconstant. At last she was compelled, by the public indignation, to banish this unworthy minion; and he was no sooner gone, than her regard for him was at an end. She was ashamed of the favour he had shewn him; and, in a short time, thought of him with hatred or contempt. This Bourdelot, during his ascendancy over the queen, had supplanted count Magnus de la Gardie, son of the constable of Sweden, who was a relation, a favourite, and perhaps the lover of Christina. M. de Morteville, who had seen him am-

ballador in France, says, in his memoirs, that he spoke of his queen in terms so passionate and respectful, that every one concluded his attachment to her to be more ardent and tender, than a more sense of duty can produce. This nobleman fell into disgrace because he shewed an inclination to govern; while M. Bourdelot seemed to aim at nothing more than to amuse, and concealed, under the unsuspected character of a droll, the real ascendancy which he exercised over the queen's mind.

About this time, an accident happened to Christina which brought her into still greater danger than that which has been related already. Having given orders for some ships of war to be built at the port of Stockholm, she went to see them when they were finished; and as she was going on board of them, cross a narrow plank, with admiral Fleming, his foot slipping, he fell, and drew the queen with him into the sea, which in that place was near 90 feet deep. Anthony Steinberg, the queen's first eunuch, instantly threw himself into the water, laid hold of her robe, and, with such assistance as was given him, got the queen ashore: during this accident, her recollection was such, that the moment her lips were above water, she cried out, "Take care of the Admiral." When she was got out of the water, she discovered no emotion either by her gesture or countenance; and she dined the same day in public, where she gave a humorous account of her adventure.

But, though at first she was fond of the power and splendor of royalty, yet she began at length to feel that it embarrassed her; and the same love of independence and liberty which had determined her against marriage, at last made her weary of her crown. As, after her first disgust, it grew more and more irksome to her, she resolved to abdicate; and, in 1652, communicated her resolution to the senate. The senate zealously remonstrated against it; and was joined by the people; and even by Charles Gustavus himself, who was to succeed her: she yielded to their importunities, and continued to sacrifice her own pleasure to the will of the public till the year 1654, and then she carried her design into execution. It appears by one of her letters to M. Canut, in whom she put great confidence, that she had meditated this project for more than eight years; and that she had communicated it to him five years before it took place.

The ceremony of her abdication was a mournful solemnity, a mixture of pomp and sadness, in which scarce any eyes but her own were dry. She continued firm and composed through the whole; and, as soon as it was over, prepared to remove into a country more favourable to science than Sweden was. Concerning the merit of this action, the world has always been divided in opinion; it has been condemned alike both by the ignorant and the learned, the trifler and the sage. It was admired, however, by the great Conde: "How great was the magnanimity of this princess, (said he), who could so easily give up that for which the rest of mankind are continually destroying each other, and which so many, throughout their whole lives pursue, without attaining!" It appears, by the works of St Evremont, that the abdication of Christina was at that time the universal to-

Christina.

Christina.

pic of speculation and debate in France. Christina, besides abdicating her crown, abjured her religion: but this act was universally approved by one party and censured by another; the Papists triumphed, and the Protestants were offended. No prince, after a long imprisonment, ever shewed so much joy upon being restored to his kingdom, as Christina did in quitting hers. When she came to a little brook, which separates Sweden from Denmark, she got out of her carriage; and leaping to the other side, cried out in a transport of joy, "At last I am free, and out of Sweden, whither, I hope, I shall never return." She dismissed her women, and laid by the habit of her sex: "I would become a man," (said she); yet I do not love men because they are men, but because they are not women." She made her abjuration at Brussels; where she saw the great Conde, who, after his defection, made that city his asylum. "Cousin," (said she), who would have thought, ten years ago, that we should have met at this distance from our countries?"

The inconstancy of Christina's temper appeared in her going continually from place to place: from Brussels she went to Rome; from Rome to France, and from France she returned to Rome again; after this she went to Sweden, where she was not very well received; from Sweden she went to Hamburg, where she continued a year, and then went again to Rome; from Rome she returned to Hamburg; and again to Sweden, where she was still worse received than before; upon which she went back to Hamburg, and from Hamburg again to Rome. She intended another journey to Sweden; but it did not take place, any more than an expedition to England, where Cromwell did not seem well disposed to receive her; and after many wanderings, and many purposes of wandering still more, she at last died at Rome in 1689.

It must be acknowledged, that her journeys to Sweden had a motive of necessity; for her appointments were very ill paid, though the states often confirmed them after her abdication: but to other places she was led merely by a roving disposition; and, what is more to her discredit, she always disturbed the quiet of every place she came into, by exacting greater deference to her rank as queen than she had a right to expect, by her total non-conformity to the customs of the place, and by continually exciting and fomenting intrigues of state. She was indeed always too busy, even when she was upon the throne; for there was no event in Europe in which she was not ambitious of acting a principal part. During the troubles in France by the faction called the *Fronde*, she wrote with great eagerness to all the interested parties, officially offering her mediation to reconcile their interests, and calm their passions, the secret springs of which it was impossible she should know. This was first thought a dangerous, and afterwards a ridiculous behaviour. During her residence in France she gave universal disgust, not only by violating all the customs of the country, but by practising others directly opposite. She treated the ladies of the court with the greatest rudeness and contempt: when they came to embrace her, she, being in man's habit, cried

out, "What a strange eagerness have these women to kiss me! it is because I look like a man?"

But though she ridiculed the manners of the French court, she was very solicitous to enter into its intrigues. Lewis XIV. then very young, was enamoured of Mademoiselle de Mancini, niece to cardinal Mazarine; Christina flattered their passion, and offered her service. "I would fain be your confidant," (said she;) if you love, you must marry."

The murder of Monaldeschi is, to this hour, an inscrutable mystery. It is, however, of a piece with the expressions constantly used by Christina in her letters, with respect to those with whom she was offended; for the scarce ever signified her displeasure without threatening the life of the offender. "If you fail in your duty," (said she to her secretary, whom she sent to Stockholm after her abdication), not all the power of the king of Sweden shall save your life, though you should take shelter in his arms." A musician having quitted her service for that of the duke of Savoy, she was so transported with rage as to disgrace herself by these words, in a letter written with her own hand: "He lives only for me; and if he does not sing for me, he shall not sing long for any body."

Bayle was also threatened for having said that the letter which Christina wrote, upon the revocation of the edict of Nantes, was "a reman of Protestantism;" but he made his peace by apologies and submission. See the article BAYLE.

Upon the whole, she appears to have been an uncommon mixture of faults and great qualities; which, however it might excite fear and respect, was by no means amiable. She had wit, taste, parts, and learning: she was indefatigable upon the throne; great in private life; firm in misfortunes; impatient of contradiction; and, except in her love of letters, inconstant in her inclinations. The most remarkable instance of this fickleness is, That after she had abdicated the crown of Sweden, she intrigued for that of Poland. She was, in every action and pursuit, violent and ardent in the highest degree; impetuous in her desires, dreadful in her resentment, and fickle in her conduct. She says of herself, that "she was mistrustful, ambitious, passionate, haughty, impatient, contemptuous, satirical, incredulous, undevout, of an ardent and violent temper, and extremely amorous;" a disposition, however, to which, if she may be believed, her pride and her virtue were always superior. In general, her failings were those of her sex, and her virtues the virtues of ours.

Santa-CHRISTINA, one of the *MARQUESAS Islands*.

CHRISTMAS-DAY, a festival of the Christian church; observed on the 25th of December, in memory of the *nativity* or birth of Jesus Christ. As to the antiquity of this festival, the first footsteps we find of it are in the second century, about the time of the emperor Commodus. The decretal epistles indeed carry it up a little higher; and say that Telephorus, who lived in the reign of Antoninus Pius, ordered divine service to be celebrated, and an angelical hymn to be sung, the night before the nativity of our Saviour. However, that it was kept before the times of Constantine we have a melancholy proof: for whilst the persecution raged under Dioclesian, who then kept

phers
Chromatic.

kept his court at Nicomedia, that prince, among other acts of cruelty, finding multitudes of Christians assembled together, to celebrate Christ's nativity, commanded the church-doors where they were met, to be shut, and fire to be put to it, which, in a short time, reduced them and the church to ashes.

CHRISTOPHERS, St. one of the Caribbee islands, in America, lying to the north-west of Nevis, and about 60 miles west of Antigua. It was formerly inhabited by the French and English; but, in 1713, it was ceded to the latter. It is about 20 miles in breadth, and 7 in length; and has high mountains in the middle, whence rivulets run down. Between the mountains are dreadful rocks, horrid precipices, and thick woods; and in the fourth-west part of the island, hot sulphurous springs at the foot of them. The air is good; the soil light, sandy, and fruitful; but the island is subject to hurricanes. The produce is chiefly sugar, cotton, ginger, indigo, and the tropical fruits. W. Long. 62.32. N. Lat. 17.30.

CHROASTACES, in natural history, a genus of pellicul gems, comprehending all those of variable colours, as viewed in different lights; of which kinds are the *opal* and the *asteria* or *oculus cati*. See *OPAL*, and *ASTERIA*.

CHROMATIC, a kind of music which proceeds by several semitones in succession. The word is derived from the Greek *χρῶμα*, which signifies colour. For this denomination several causes are assigned, of which none appear certain, and all equally unsatisfactory. Instead, therefore, of fixing upon any, we shall offer a conjecture of our own; which, however, we do not impose upon the reader, as more worthy of his attention than any of the former. *Χρῶμα* may perhaps not only signify a colour, but that shade of a colour by which it melts into another, or what the French call *nuance*. If this interpretation be admitted, it will be highly applicable to semitones; which being the smallest interval allowed in the diatonic scale, will most easily run one into another. To find the reasons assigned by the ancients for this denomination, and their various divisions of the chromatic species, the reader may have recourse to the same article in Rousseau's Musical Dictionary. At present, that species consists in giving such a procedure to the fundamental bass, that the parts in the harmony, or at least some of them, may proceed by semitones, as well in rising as descending; which is most frequently found in the minor mode, from the alterations to which the sixth and seventh note are subjected, by the nature of the mode itself.

The successive semitones used in the *chromatic* species are rarely of the same kind; but alternatively major and minor, that is to say, *chromatic* and *diatonic*: for the interval of a minor tone contains a minor or chromatic semitone, and another which is major or diatonic; a measure which temperament renders common to all tones: so that we cannot proceed by two minor semitones which are conjunctive in succession, without entering into the enharmonic species; but two major semitones twice follow each other in the *chromatic* order of the scale.

The most certain procedure of the fundamental bass to generate the chromatic elements in ascent, is alternately to descend by thirds, and rise by fourths, whilst all the chords carry the third major. If the fundamental bass proceeds from dominant to dominant by perfect cadences avoided, it produces the *chromatic* in descending. To produce both at once, you interweave the perfect and broken cadences, but at the same time avoid them.

As at every note in the *chromatic* species one must change the tone, that succession ought to be regulated and limited for fear of deviation. For this purpose, it will be proper to recollect, that the space most suitable to *chromatic* movements, is between the extremes of the dominant and the tonic in ascending, and between the tonic and the dominant in descending. In the major mode, one may also chromatically descend from the dominant upon the second note. This transition is very common in Italy; and, notwithstanding its beauty, begins to be a little too common amongst us.

The chromatic species is admirably fitted to express grief and affliction: these sounds boldly struck in ascending tear the soul. Their power is no less magical in descending; it is then that the ear seems to be pierced with real groans. Attended with its proper harmony, this species appears proper to express every thing: but its completion, by concealing the melody, sacrifices a part of its expression; and for this disadvantage, arising from the fullness of the harmony, it can only be compensated by the nature and genius of the movement. We may add, that, in proportion to the energy of this species, the composer ought to use it with greater caution and parsimony. Like those delicate viands, which, when profusely administered, immediately sicken us with their abundance: as much as they delight us when enjoyed with temperance, so much do they disgust when devoured with prodigality.

CHROMATIC, *Enharmonic*. See *ENHARMONIC*.

C H R O M A T I C S;

THAT part of optics which explains the several properties of the colours of light, and of natural bodies.

Different hypotheses concerning colours.

Before the time of Sir Isaac Newton, we find no hypothesis concerning colours of any consequence. The opinions of the old philosophers, however, we shall briefly mention, in order to gratify the curiosity of our readers. The Pythagoreans called colour the superficies

of body. Plato said that it was a flame issuing from them. According to Zeno, it is the first configuration of matter; and Aristotle said it was that which moved bodies actually transparent. Descartes asserted, that colour is a modification of light; but he imagined, that the difference of colour proceeds from the prevalence of the direct or rotatory motion of the particles of light. Father Grimaldi, Dechales, and many others,

thought the differences of colour depended upon the quick or slow vibrations of a certain elastic medium filling the whole universe. Rohault imagined, that the different colours were made by the rays of light entering the eye at different angles with respect to the optic axis; and from the phenomenon of the rainbow he pretended to calculate the precise quantity of the angle that constituted each particular colour. Lastly, Dr Hooke, the rival of Newton, imagined that colour is caused by the sensation of the oblique or uneven pulse of light; and this being capable of no more than two varieties, he concluded there could be no more than two primary colours.

2
This subject
investigated
by Sir Isaac
Newton.

In the year 1666, Sir Isaac Newton began to investigate this subject; and finding the coloured image of the sun, formed by a glass prism, to be of an oblong, and not of a circular form, as, according to the laws of refraction, it ought to be, he began to conjecture that light is not *homogeneous*; but that it consists of rays, some of which are much more refrangible than others. See this discovery fully explained and ascertained under the article OPTICS.

This method of accounting for the different colours of bodies, for their reflecting this or that kind of rays most copiously, is so easy and natural, that Sir Isaac's system quickly overcame all objections, and to this day continues to be almost universally believed. It is now acknowledged, that the light of the sun, which to us seems perfectly homogeneous and white, is composed of no fewer than seven different colours, *viz.* red, orange, yellow, green, blue, purple, and violet or indigo. A body which appears of a red colour, hath the property of reflecting the red rays more powerfully than any of the others; and so of the orange, yellow, green, &c. A body which is of a black colour, instead of reflecting, *absorbs* all or the greatest part of the rays that fall upon it; and, on the contrary, a body which appears white, reflects the greatest part of the rays indiscriminately, without separating the one from the other.

The foundation of a rational theory of colours being thus laid, it next became natural to inquire, by what peculiar mechanism in the structure of each particular body it was fitted to reflect one kind of rays more than another. This Sir Isaac Newton attributes to the density of these bodies. Dr Hooke had remarked, that thin transparent substances, particularly water and soap blown into bubbles, exhibited various colours according to their thinness; though, when they have a considerable degree of thickness, they appear colourless; and Sir Isaac himself had observed, that as he was compressing two prisms hard together, in order to make their sides (which happened to be a little convex) to touch one another, in the place of contact they were both perfectly transparent, as if they had been but one continued piece of glass. Round the point of contact, where the glasses were a little separated from each other, rings of different colours appeared. To observe more nicely the order of the colours produced in this manner, he took two object-glasses; one of them a plano-convex one belonging to a 14 foot reflecting telescope, and the other a large double convex one for a telescope of about 50 feet; and laying the former of them upon the latter, with its plain side

3
Colours appearing
between two
glass plates.

downwards, he pressed them slowly together; by which means the colours very soon emerged, and appeared distinct to a considerable distance. Next to the pellucid central spot, made by the contact of the glasses, succeeded blue, white, yellow, and red. The blue was very little in quantity, nor could he discern any violet in it; but the yellow and red were very copious, extending about as far as the white, and four or five times as far as the blue. The next circuit immediately surrounding these, consisted of violet, blue, green, yellow, and red: all these were copious and vivid except the green, which was very little in quantity, and seemed more faint and dilute than the other colours. Of the other four the violet was the least in extent; and the blue less than the yellow or red. The third circle of colours was purple, blue, green, yellow, and red. In this the purple seemed more reddish than the violet in the former circuit, and the green was more conspicuous; being as brisk and copious as any of the other colours, except the yellow; but the red began to be a little faded, inclining much to purple. The fourth circle consisted of green and red; and of these the green was very copious and lively, inclining on the one side to blue, and on the other to yellow; but in this fourth circle there was neither violet, blue, nor yellow, and the red was very imperfect and dirty. All the succeeding colours grew more and more imperfect and dilute, till, after three or four revolutions, they ended in perfect whiteness.

4
As the colours were thus found to vary, according to the different distances of the glass-plates from each other, our author thought that they proceeded from the different thickness of the plate of air intercepted between the glasses; this plate of air, being by the mere circumstance of thinness or thickness, disposed to reflect or transmit this or that particular colour. From this he concluded, as already observed, that the colours of all natural bodies depended on their density, or the bigness of their component particles. He also constructed a table wherein the thickness of a plate necessary to reflect any particular colour was expressed in parts of an inch divided into 1,000,000 parts.

5
Sir Isaac Newton, pursuing his discoveries concerning the colours of thin substances, found that the same were also produced by plates of a considerable thickness. There is no glass or speculum, he observes, how well polished soever, but, besides the light which it refracts or reflects regularly, scatters every way irregularly a faint light; by means of which the polished surface, when illuminated in a dark room by a beam of the sun's light, may easily be seen in all positions of the eye. It was with this scattered light that the colours in the following experiments were produced.

Colours by
reflection.

The sun shining into his darkened chamber through a hole in the shutter one inch wide, he let the beam of light fall perpendicularly upon a glass speculum concave on one side and convex on the other, ground to a sphere of five feet eleven inches radius, and quicksilver over on the convex side. Then, holding a quire of white paper at the centre of the sphere to which the speculum was ground, in such a manner as that the beam of light might pass through a little hole made in the middle of the paper, to the speculum, and thence

be

be reflected back to the same hole, he observed on the paper four or five concentric rings of colours, like rainbows surrounding the hole, very much like those which appeared in the thin plates above-mentioned, but larger and fainter. These rings, as they grew larger and larger, became more dilute, so that the fifth was hardly visible; and yet sometimes, when the sun shone very clear, there appeared faint traces of a sixth and seventh.

We have already taken notice, that the thin plates made use of in the former experiments reflected some kinds of rays in particular parts, and transmitted others in the same parts. Hence the coloured rings appeared variously disposed, according as they were viewed by transmitted or reflected light; that is, according as the plates were held up between the light and the eye, or not. For the better understanding of which we subjoin the following table, wherein on one side are mentioned the colours appearing on the plates by reflected light, and on the other those which were opposite to them, and which became visible when the glasses were held up between the eye and the window. We have already observed, that the centre, when the glasses were in full contact, was perfectly transparent. This spot, therefore, when viewed by reflected light, appeared black, because it transmitted all the rays; and for the same reason it appeared white when viewed by transmitted light.

The colours of the rings produced from reflection by the thick plates, followed the order of those produced by transmission through the thin ones; and by the analogy of their phenomena with those produced from the thin plates, Sir Isaac Newton concluded that they were produced in a similar manner. For he found, that if the quicksilver was rubbed off from the back of the speculum, the glass alone would produce the same rings, but much more faint than before; so that the phenomenon did not depend upon the quicksilver, except in as far as, by increasing the reflexion at the back of the glass, it increased the light of the coloured rings. He also found that a speculum of metal only, produced none of those rings; which made

him conclude, that they did not arise from one surface only, but depended on the two surfaces of the plate of glass of which the speculum was made, and upon the thickness of the glass between them.

From these experiments and observations, it will be easy to understand the Newtonian theory of colours. Every substance in nature seems to be transparent, provided it is made sufficiently thin. Gold, the most dense substance we know, when reduced into thin leaves, transmits a bluish green light through it. If therefore we suppose any body, gold, for instance, to be divided into a vast number of plates, so thin as to be almost perfectly transparent, it is evident, that all or greatest part of the rays will pass through the upper plates, and when they lose their force will be reflected from the under ones. They will then have the same number of plates to pass through, which they had penetrated before; and thus, according to the number of those plates through which they are obliged to pass, the object appears of this or that colour, just as the rings of colours appeared different in the experiment of the two plates, according to their distance from one another, or the thickness of the plate of air between them.

This theory is adopted by Edward Huxley Delaval, in his Experimental Inquiry into the cause of the changes of colours in opaque and coloured bodies. He endeavours to confirm it by a number of experiments on the infusions of flowers of different colours; but his strongest arguments seem to be those derived from the different tinges given to glass by metallic substances. Here he observes, that each metal gives a tinge according to its specific density; the more dense metals producing the less refrangible colours, and the lighter ones those colours which are more easily refrangible. Gold, which is the densest of all metals, imparts a red colour to glass, whenever it can be divided into particles so minute, that it is capable of being mixed with the materials of which glass is made. It seems indifferent by what means it is reduced to this state, nor can it by any means be made to produce another colour. If it is mixed in large masses without being minutely divided, it imparts no colour to the glass, but remains in its metallic form. Lead, the metal whose density is next in order to that of gold, affords a glass of the colour of the hyacinth; a gem whose distinguishing characteristic is, that it is red with an admixture of yellow, the same colour which is usually called *orange*. Glass of lead is mentioned by several authors as a composition proper, without the addition of any other ingredient, for imitating the hyacinth. Silver, next in density to lead, can only be made to communicate a yellow colour to glass. If the metal is calcined with sulphur, it readily communicates this colour. Leaf-silver laid upon red-hot glass likewise tinges it yellow. When we meet with authors who mention a blue or greenish colour communicated by silver, the cause must have been, that the silver used in such processes was mixed with copper. Mr Delaval assures us, from his own experience, that silver purified by the test retains so much copper, that, when melted several times with nitre and borax, it always imparted a green colour at the first and second melting; though afterwards no such

General theory of colours by Sir Isaac Newton.

Mr Delaval's experiments in confirmation of it.

Colours by refraction and reflection enumerated.

such colour was obtainable from it. The only colour produced by copper is green. It is indifferent in what manner the copper is prepared in order to tinge the glass, provided it is exposed without any other ingredient to a sufficient degree of heat. If a quantity of salts are added in the preparation, they will, by attenuating the mixture, make the glass incline to blue, the colour next in order; but this happens only when the fire is moderate: for, in a greater degree of heat, the redundant salts, even those of the most fixed nature, are expelled. It is true, that copper is mentioned by some writers as an ingredient in red glass and enamel: but the red, which is the colour of the metal not dissolved or mixed with the glass, remains only while the composition is exposed to such a degree of heat as is too small to melt and incorporate it; for, if it be suffered to remain in the furnace a few minutes after the copper is added, the mass will turn out green instead of red. Iron, the metal next in density to copper, is apt to be calcined, or reduced to a ruddy crocus, similar to that rust which it contracts spontaneously in the air. In this state it requires a considerable degree of heat to dissolve and incorporate it with glass: till that heat is applied, it retains its ruddy colour: by increasing the heat, it passes through the intermediate colours, till it arrives at its permanent one which is blue; this being effected in the greatest degree of heat the glass will bear, without losing all colour whatever. Iron vitrified *per se*, is converted into a blue glass. In short, it is indubitable, that iron is the only metal which will, without any addition, impart to the glass a blue colour: for copper will not communicate that colour without the addition of a considerable quantity of salts, or some other matter that attenuates it; and the other metals cannot by any means be made to produce it at all.

9
Sir Isaac's
theory de-
fended by
Dr Priest-
ley.

These are the principal of Mr Delaval's arguments in favour of Sir Isaac Newton's theory of colours being formed by density. Dr Priestley too hath mentioned some which deserve attention. "It was a discovery of Sir Isaac Newton, (says he), that the colours of bodies depend upon the thickness of the fine plates which compose their surfaces. He hath shown, that a change of the thickness of these plates occasions a change in the colour of the body; rays of a different colour being thereby disposed to be transmitted through it; and consequently rays of a different colour reflected at the same place, so as to present an image of a different colour to the eye. A variation in the density occasions a variation in the colour; but still a medium of any density will exhibit all the colours, according to the thickness of it. These observations he confirmed by experiments on plates of air, water, and glass. He likewise mentions the colours which arise on polished steel by heating it, as likewise on bell-metal, and some other metalline substances, when melted and poured on the ground, where they may cool in the open air; and he ascribes them to the scorie or vitrified parts of the metal, which, he says, most metals, when heated or melted, do continually protrude and send out to their surfaces, covering them in the form of a thin glassy skin. This great discovery concerning the colours of bodies depending on the thickness of the fine plates which compose their

surfaces, of whatever density these plates may be, I have been so happy as to hit upon a method of illustrating and confirming by means of electrical explosions. A number of these being received on the surface of any piece of metal, change the colour of it to a considerable distance from the spot on which they were discharged; so that the whole circular space is divided into a number of concentric rings, each of which consists of all the prismatic colours, and perhaps as vivid as they can be produced in any method whatever. Upon shewing these coloured rings to Mr Canton, I was agreeably surprised to find, that he had likewise produced all the prismatic colours from all the metals, but by a different operation. He extended fine wires of all the different metals along the surfaces of pieces of glass, ivory, wood, &c.; and when the wire was exploded, he always found them tinged with all the colours. They are not disposed in so regular and beautiful a manner as in the rings I produced, but they equally demonstrate that none of the metals thus exploded discovers the least preference to one colour more than to another. In what manner these colours are formed may not be easy to conjecture. In Mr Canton's method of producing them, the metal, or the calcined and vitrified parts of it seem to be dispersed in all directions from the place of explosion, in the form of spheres of a very great variety of sizes, tinged with all the variety of colours, and some of them smaller than can be distinctly seen by any magnifier. In my method of making these colours, they seem to be produced in a manner similar to the production of colours on steel and other metals by heat; *i. e.* the surface is affected without the parts of it being removed from their places, certain plates or laminae being formed of a thickness proper to exhibit the respective colours."

But, however well supported this doctrine of the formation of colours by density may be, we find the same author (Dr Priestley), whom we have just now seen arguing for it in his history of electricity, arguing against it in his history of vision. "There are (says he) no optical experiments with which Sir Isaac Newton seems to have taken more pains than those relating to the rings of colours which appear in thin plates; and in all his observations and investigations concerning them, he discovers the greatest sagacity both as a philosopher and mathematician; and yet in no subject to which he gave his attention, does he seem to have overlooked more important circumstances in the appearances he observed, or to have been more mistaken with regard to their causes. The former will be evident from the observations of those who succeeded him in these inquiries, particularly those of the Abbe Mazeas. This gentleman, endeavouring to give a very high polish to the flat side of an object-glass, happened to be rubbing it against another piece of flat and smooth glass; when he was surprised to find, that after this friction, they adhered very firmly together, till at last he could not move the one upon the other. But he was much more surprised to observe the same colours between these plane glasses that Newton observed between the convex object-glass of a telescope and another that was plane. These colours between the plane glasses, the Abbe observed, were in proportion

tion to their adhesion. The resemblance between them and the colours produced by Newton induced him to give a very particular attention to them; and his observations and experiments are as follow:

"If the surfaces of the pieces of glass are transparent, and well polished, such as are used for mirrors, and the pressure be as equal as possible on every part of the two surfaces, a resistance, he says, will soon be perceived when one of them is made to slide over the other; sometimes towards the middle, and sometimes towards the edges; but wherever the resistance is felt, two or three very fine curve lines will be perceived, some of a pale red, and others of a faint green. Continuing the friction, these red and green lines increase in number at the place of contact, the colours being sometimes mixed without any order, and sometimes disposed in a regular manner. In the last case, the coloured lines are generally concentric circles, or ellipses; or rather ovals, more or less elongated as the surfaces are more or less united. These figures will not fail to appear, if the glasses are well wiped and warmed before the friction.

"When the colours are formed, the glasses adhere with considerable force, and would always continue so without any change in the colours. In the centre of all those ovals, the longer diameter of which generally exceeds ten lines, there appears a small plate of the same figure, exactly like a plate of gold interposed between the glasses; and in the centre of it there is often a dark spot, which absorbs all the rays of light except the violet; for this colour appears very vivid through a prism.

"If the glasses are separated suddenly, either by sliding them horizontally over one another, or by the action of fire, as will be explained hereafter, the colours will appear immediately upon their being put together again, without the least friction.

"Beginning by the slightest touch, and increasing the pressure by insensible degrees, there first appears an oval plate of a faint red, and in the midst of it a spot of light green, which enlarges by the pressure, and becomes a green oval, with a red spot in the centre; and this, enlarging in its turn, discovers a green spot in its centre. Thus the red and the green succeed one another in turns, assuming different shades, and having other colours mixed with them, which will be distinguished presently.

"The greatest difference between these colours exhibited between plane surfaces and those formed by curve ones is, that in the former case pressure alone will not produce them, except in the case above mentioned. With whatever force he compressed them, his attempts to produce the colours were in vain without previous friction. But the reason of this plainly was, that without sliding one of the glasses over the other, they could not be brought to approach near enough for the purpose.

"Having made these observations with plates of glass whose sides were nearly parallel, he got two prisms with very small refracting angles; and rubbing them together, when they were so joined as to form a paralleloiped, the colours appeared with a surprising lustre at the places of contact, owing, he did not doubt, to the separation of the rays of light

by the prism. In this case, differently coloured ovals appeared, but the plate of gold in them was much whiter, and only appeared yellow about its edges. This plate having a black spot in its centre, was bordered by a deep purple. He could not perceive any violet by his naked eye, but it might be perceived by the help of a lens with a weak light. It appeared in a very small quantity at the confines of the purple and the blue, and seemed to him to be only a mixture of these two colours. It was very visible in each of the coloured rings by inclining the glasses to the light of the moon. Next to the purple and violet appeared blue, orange, red tinged with purple, light green, and faint purple. The other rings appeared to the naked eye to consist of nothing but faint reds and greens; and they were so shaded that it was not easy to mark their terminations. That the order of these may be compared with Newton's, he gives a view of both in the following table:

Order of the Colours in the Plane Glasses.		Order of the Colours in Newt. Object Glasses.
Order I.	{ Black spot	Black
	{ Whitish oval	Blue
	{ Yellow border	White
	{ Deep purple	Yellow
Order II.	{ Blue	Red
	{ Orange	Violet
	{ Purple	Blue
		Green
Order III.	{ Greenish blue	Yellow
	{ Yellowish green	Red
	{ Purplish red	Purple
		Blue
Order IV.	{ Green	Green
	{ Red	Red
Order V.	{ Faint green	Greenish blue
	{ Faint red	Red
Order VI.	{ Weak green	Greenish blue
	{ Light red	Red
Order VII.	{ Very faint green	Greenish blue
	{ Very faint red.	Pale red

"When these coloured glasses were suspended over the flame of a candle, the colours disappeared suddenly, though the glasses still continued to adhere to one another when they were parallel to the horizon. When they were suffered to cool, the colours returned by degrees to their former places, in the order of the preceding table.

"After this the Abbe took two plates much thicker than the former, in order to observe at his leisure the action of fire upon the matter which he supposed to produce the colours; and observed, that as they grew warm, the colours retired to the edges of the glasses, and there became narrower and narrower till they were reduced to imperceptible lines. Withdrawing the flame, they returned to their place. This experiment he continued till the glasses were bent by the violence of the heat. It was pleasant, he says, to observe these colours glide over the surface of the glass as they were pursued by the flame.

"At

"At the first, our author had no doubt but that these colours were owing to a thin plate of air between the glasses, to which Newton has ascribed them; but the remarkable difference in the circumstances attending those produced by the flat plates, and those produced by the object-glasses of Newton, convinced him that the air was not the cause of this appearance. The colours of the flat plates vanished at the approach of flame, but those of the object-glasses did not. He even heated the latter till that which was next the flame was cracked by the heat, before he could observe the least dilatation of the coloured rings. This difference was not owing to the plane glasses being less compressed than the convex ones; for though the former were compressed ever so much by a pair of forceps, it did not in the least hinder the effect of the flame.

"Afterwards he put both the plane glasses and the convex ones, into the receiver of an air-pump, suspending the former by a thread, and keeping the latter compressed by two strings; but he observed no change in the colours of either of them in the most perfect vacuum he could make.

"Notwithstanding these experiments seemed to be conclusive against the hypothesis of these colours being formed by a plate of air, the Abbe frankly acknowledges, that the air may adhere so obliquately to the surface of the glasses as not to be separated from them by the force of the pump; which, indeed, is agreeable to other appearances: but the following experiments of our author make it still more improbable that the air should be the cause of these colours.

"To try the utmost effect of heat upon these coloured plates, after warming them gradually, he laid them upon burning coals; but though they were nearly red, yet when he rubbed them together, by means of an iron rod, he observed the same coloured circles and ovals as before. When he ceased to press upon them, the colours seemed to vanish; but, when he repeated the friction, they returned, and continued till the pieces of glass began to be red-hot, and their surfaces to be united by fusion.

"When the outward surface of one of his plates of glass was quicksilvered, none of those colours were visible, though the glasses continued to adhere with the same force. This he ascribed to the stronger impression made on the eye by the greater quantity of light reflected from the quicksilver.

"Judging from the resemblance between his experiments and those of Sir Isaac Newton, that the colours were owing to the thickness of some matter, whatever that was, interposed between the glasses, the Abbe, in order to verify his hypothesis, tried the experiment on thicker substances. He put between his glasses a little ball of suet, about a fourth of a line in diameter, and pressed it between the two surfaces, warming them at the same time, in order to disperse the suet; but, though he rubbed them together as before, and used other soft substances besides suet, his endeavours to produce the colours had no effect. But, rubbing them with more violence in a circular manner, he was surprised, on looking at a candle through them, to see it surrounded with two or three concentric rings, very broad, and with very lively delicate

colours; namely, a red inclining to a yellow, and a green inclining to that of an emerald. At that time he observed only these two colours; but continuing the friction, the rings assumed the colours of blue, yellow, and violet, especially when he looked through the glasses on bodies directly opposed to the sun. If, after having rubbed the glasses, the thickness was considerably diminished, the colours grew weaker by transmitted light, but they seemed to be much stronger by reflection, and to gain on one side what they lost on the other.

"Our author was confirmed in his opinion, that there must be some error in Newton's hypothesis, by considering, that, according to his measures, the colours of the plates varied with the difference of a millionth part of an inch, whereas he was satisfied that there must have been much greater differences in the distance between his glasses, when the colours remained unchanged.

"If the colour depended upon the thickness only, he thought that the matter interposed between the glasses ought to have given the same colour when it was reduced to a thin plate by simple fusion as well as by friction, and that, in rubbing two plates together, warming them at different times, and compressing them with a considerable force, other colours would have appeared besides those above-mentioned.

"These circumstances made him suspect, that the different thicknesses of the substance interposed between the glasses served only to make them more or less transparent, which was an essential condition in the experiment; and he imagined that the friction diffused over the surface of the thin substance a kind of matter on which the colours are formed by reflected light; for when he held the plates (which gave the colours when the suet was between them) over the flame of a small candle, the colours fled with great precipitation, and returned to their place without his being able to perceive the least alteration in the suet.

"He was confirmed in his conjectures, by frequently observing, that when the glasses were separated, at the moment the colours disappeared, they were covered with the same greasy matter, and that it seemed to be in the very same state as when they were separated without warming. Besides, having often repeated the same experiment with different kinds of matter, he found that the degree of heat that dispersed the colours was not always sufficient to melt it; which difference was more sensible in proportion as the matter interposed was made thinner.

"Instead of the suet, he sometimes made use of Spanish wax, resin, common wax, and the sediment of urine. He began with Spanish wax, on account of its remarkable transparency in Mr Hauksbee's electrical experiments; but he had much difficulty in making it sufficiently thin by friction, being often obliged to warm his glasses, to seize the moment of fusion, which continued but a short time, and to hazard the burning of his fingers.

"The experiment at length succeeding, the Spanish wax appeared with its opacity and natural colour when it reflected the light, but they both disappeared in the transmitted light. He observed the same rings in it as in the suet; and indeed he could perceive but

14
Newtonian
hypothesis
opposed.

little difference between the colours of suet, Spanish wax, common wax, or resin; except that this last substance did not make the colours so vivid, on account of the too great transparency of its particles.

"The sediment of urine had something more particular in its appearance, as its colours were more lively. Holding it above the flame, its colours disappeared; and, keeping it in that situation, there were formed, upon its surface, ramifications, like those of the hoar-frost, which disappeared as the glasses grew cold. There were the same ramifications both upon the suet and the wax, but they were not so considerable. The glasses which had Spanish wax and resin between them adhered with so much force, that they could not be separated without the help of fire; and when they began to grow warm, they separated with a noise like that of a glass breaking in the fire, though the glasses were not broken, and the matter between them was not melted.

"Separating the glasses which he first used very suddenly, he observed upon their surface very thin vapours, which formed different colours, but presently vanished altogether.

"To try the effect of vapour, he breathed upon one of his plates of glass, and observed that the vapours which adhered to the glasses sometimes formed, before they were entirely dispersed, a surprising variety of colours. This experiment, he observes, does not always succeed at the first trial. The glass must be breathed upon several times, and care must be taken to wipe it every time with one's hand, both to take off the moisture, and also to make upon the glass a kind of furrows, which contribute very much to the variety of colours, by making inequalities in the thicknesses of the vapours. It is necessary, also, that the glasses on which these experiments are made have no quicksilver upon them.

"When the particles of water which formed this vapour were too thick to exhibit these colours, he struck them several times with his pencil, in order to attenuate them; and then he saw an infinity of small coloured threads which succeeded one another with great rapidity.

"Putting a drop of water between two pieces of common glass, he observed that the compression of them produced no colour; but if, while they were compressed, the water was made to pass from one place to another, it left behind it large spots, red, yellow, green, purple, &c. and the spots assumed different colours with a surprising rapidity, and presented to the eye a most beautiful variety of shades.

"In order to determine with greater certainty whether they were vapours that caused the colours in his first observations, he first breathed upon one of his plates of glass, and then rubbed them against one another, when the colours appeared in the same order as before, but darker, and dispersed in confusion in the places occupied by the vapours; but when he made use of fire to dissipate the watery particles, the colours resumed their lustre.

"Newton, having introduced a drop of water between his two object-glasses, observed, that in proportion as the water insinuated itself between the glasses, the colours grew fainter, and the rings were

contracted; and ascribing these colours to the thickness of the plate of water, as he ascribed the former to that of the plate of air, he measured the diameters of the coloured rings made by the plate of water, and concluded that the intervals between the glasses at the similar rings of these two mediums were nearly as three to four; and thence he inferred that, in all cases, these intervals would be as the sines of the refractions of these mediums.

"The Abbe Mazeas, in order to assure himself whether, agreeable to this rule, the coloured rings of his glasses depended upon the thickness of the water only, dipped one of the edges of his coloured glasses in a vessel of water, having taken care to wipe and warm them well before he produced his colours by friction. The water was a considerable time in rising as high as the glasses; and in proportion as it ascended, he perceived a very thin plate of water, which seemed to pass over the matter, which he thought produced the colours, without mixing with it; for beyond this plate of water, he still perceived the colours in the same place and order, but deeper and darker; and holding the glasses above the flame of a candle, he saw the colours go and come several times as he moved them nearer to or further from the flame. He then moistened both the glasses more than before; and rubbing them as usual, he always saw the same appearance; and seizing the moment when the colours had disappeared to separate the glasses, he always found that they were wet. On this account, he thought that it could not be the water on which the colour depended, but some substance much more sensible to heat. He also thought that these coloured rings could not be owing to the compression of the glasses; or that, if this circumstance did contribute any thing to them, it served rather to modify than to generate them.

"M. du Tour gave particular attention to the preceding observations of the Abbe Mazeas. He repeated the experiments with some variation of circumstances, particularly comparing them with those of Sir Isaac Newton. He is so far from supposing a plate of air to be necessary to the formation of these coloured rings, that he thinks the reason of their not appearing between the flat plates of glass is the adhering of the air to their surfaces; and that mere pressure is not sufficient to expel it; except, as the Abbe Mazeas observed, the rings had before been made in the same place; in which case, simple apposition without friction is sufficient; the air, probably, not having had time to apply itself so closely to the surface of the glass. The contact of some other substances, M. du Tour observes, is not so prejudicial in this experiment as that of air; for he found, that, if he only gave the plates a slight coating of any kind of grease, the rings would appear without friction. Also dipping them slightly in water, or wiping them with his finger, would answer the same purpose. He verified his conjectures by means of the air-pump; for, dipping two pieces of glass in water, one of which had been wiped, and the other not, the former appeared to have no bubbles adhering to it when the air was exhausted, whereas the other had.

"When one of the glasses is convex, our author ob-

15
M. du
Tour's ob-
servations.

serves, that the particles of air may more easily make their escape by pressure only; whereas their retreat is in a manner cut off when they are compressed between two flat surfaces. The air-pump, he found, was not able to detach these particles of air from the surfaces to which they adhere; leaving these flat plates for a considerable time in an exhausted receiver, was not sufficient to prepare them so well for the experiment, as wiping them.

16
Experiments on colours by reflection.

"Besides the observations on the colours of thin plates, it has been seen that Sir Isaac Newton imagined he could account for the colours exhibited by thick ones in some cases in a similar manner; particularly in those curious experiments in which he admitted a beam of light through a hole in a piece of pasteboard, and observed the rings of colours reflected back upon it by a concave glass mirror of equal thickness in all places. These experiments were refused, and happily pursued by the Duke de Chaulnes, who ascribed these colours to the inflection of light*. Chance led the duke to observe, that when the nearer surface of the glass mirror was clouded by breathing upon it, so as lightly to tarnish it, a white diffused and vivid light was seen upon the pasteboard, and all the colours of the rings became much stronger, and more distinct. This appearance he made constant by moistening the surface of the mirror with a little milk and water, and suffering it to dry upon it.

"In all his experiments upon this subject, he found, that when the rays fell converging on the surface of the mirror, the rings were hardly visible; when they fell parallel upon it, as they must have done in all the experiments of Newton, they appeared sufficiently distinct; but when, by means of a convex lens placed in the hole of the window, they were made to diverge from the centre of the sphere to which the mirror was ground, so that they fell perpendicularly on the surface of the mirror, the colours were as vivid as he could make them. In this case he could remove the reflected image to a great distance from the hole, without making the rings disappear; and he could plainly perceive them to arise from their central spots, which changed their colours several times.

"The effect of tarnishing the mirror convinced him, that these coloured rings depended on the first surface of the mirror; and that the second surface, or that which reflected them after they had passed the first, only served to collect them and throw them upon the pasteboard in a quantity sufficient to make them visible, and he was confirmed in his supposition by the following experiments.

"He took a plano-convex object-glass, of six feet focus, and placed it six feet from the pasteboard with its convex side towards it. By this means the rays which fell upon that surface, after being refracted there, were transmitted through the thickness of the glass, parallel to one another, and fell perpendicularly on the plane surface that reflected them, and, in their return, would be collected upon the pasteboard. In these circumstances the rings appeared very distinct after he had tarnished the convex surface, which in this position was next to the light.

"Turning the same glass the contrary way, so that the plane surface was towards the pasteboard, he could

perceive none of the rings at the distance of six feet; but they were visible at the distance of three feet: because at that distance the second surface reflected the rays by its concavity directly towards the pasteboard.

"These two experiments demonstrate the use of the second surface of the mirror, and shew the manner of placing it to most advantage. Those that follow shew the use of the first surface with respect to these rings; and he was led to make them by the casual observation above-mentioned.

"Newton, he observes, had remarked that when he made use of a mirror of the same focus with the first he had used, but of twice the thickness, he found the diameter of the rings much smaller than before. This observation the duke thought favourable to his own conclusions; for if these rings depend upon the first surface, the nearer it is to the second, which only reflects the ray transmitted from it, the larger they ought to appear upon the pasteboard.

"To ascertain this fact, he thought of making use of two moveable surfaces; and to make use of a micrometer to measure the distance between them with exactness. For this purpose he took a metallic mirror belonging to a reflecting telescope, being part of a sphere of ten feet radius; and he fixed it firm upon a foot in which was a groove that carried a light frame, to which was fastened a thin piece of talc tarnished with milk and water. The frame that supported the piece of talc could either be brought into contact with the mirror, or be removed to the distance of eight or nine inches from it, and the micrometer shewed to the utmost exactness the least motion of the frame.

"Having placed this mirror ten feet from the pasteboard, that is, at the distance of the radius of its own sphere, he observed the rings to appear very distinct; the form of his mirror being very true; but the diameter of the rings upon the pasteboard varied with the distance of the talc from the mirror, so that they were very large when the talc was near the mirror, and very small when it was placed at the distance of seven or eight inches.

"These experiments proved, that the rings were formed by the first surface, and reflected by the second; but it still remained to be determined in what manner they were formed. He imagined, that the small pencils of rays that were transmitted through the pores of the glass, or any other transparent substance, might suffer a kind of inflection, which might change the cylinder which they formed into a truncated cone, either by means of their different degrees of inflexibility, or by the different distances at which they pass by the edges of the small hole through which they are transmitted. Pursuing this idea, he thought of making use of some body, the pores of which were of a known and determined shape. Instead, therefore, of the piece of talc, he placed a piece of fine linen in the above mentioned frame, stretching it as even as possible, to make the pores formed by the threads more exact and more permeable by the light; and he soon found, with great pleasure, that his conjecture was verified: for, instead of the circular rings which he had before, they were now manifestly square, though their angles were a little rounded; and they were

* See Optics.

were coloured as the others, though the light was not very vivid, on account of the quantity that was stopped by the mullin.

"When, instead of the mullin, he stretched across his frame fine silver wires exactly parallel, at the distance of about three quarters of a line, or a whole line from one another, without any other wires across them; instead of the rings which he had seen before, there was nothing upon the pasteboard but a gleam of white light divided by many small streaks, coloured in a very vivid manner, and in the same manner as the rings."

Thus we have another hypothesis of the formation of colours, namely, by the inflection of light in its passage out from between the solid and impenetrable particles of which bodies are composed. It is, however, very difficult, upon the hypothesis either of Sir Isaac Newton, or that of the Duke de Chaulnes, to give a reason why bodies that are not entirely white, should not appear variously coloured. For, it appears from Sir Isaac Newton's experiments, that plates of different density are capable of exhibiting the same colours; and that where a plate is continually varying in density, it will produce all the colours. Now it is evident, that the plates of which we suppose all natural bodies to be composed must be similar to one that is perpetually varying in its thickness; for supposing the plates of which any substance is composed, to be of any determinate thickness, $\frac{9}{10}$ millionth parts of an inch for instance; such of the rays as are reflected from this plate will be red. But if any of them penetrate to the depth of $11\frac{1}{2}$ of these parts, they will be reflected of a violet colour, &c. and thus must alloy and obscure the red; and so of others. If we suppose the colours to be produced by inflection, it will be equally difficult to account for some particular rays being inflected and others not; seeing we observe that all of them are capable of being inflected by every substance whatever, when they pass very near it. In some cases too, colours are produced when the light is neither refracted nor inflected as far as we can judge; and this seems to obscure the theory of chromatics more than any thing we have yet mentioned.

As the experiments we are now about to mention are of the greatest importance, and in direct terms contradict one of Sir Isaac Newton's, we shall give a full account of them, from Priestley's history of Vision, &c. with his remarks thereon.

The experiment in question is the eighth of Newton's second book of Optics: "He (Sir Isaac Newton) found, he says, that when light goes out of air through several contiguous refracting mediums, as through water and glass, and thence goes out again into air, whether the refracting surfaces be parallel or inclined to one another, that light, as often as, by contrary refractions, it is so corrected, that it emerges in lines parallel to those in which it was incident, continues ever after to be white; but if the emergent rays be inclined to the incident, the whiteness of the emerging light will, by degrees, in passing on from the place of emergence, become tinged at its edges with colours. This he tried by refracting light with prisms of glass, placed within a prismatic vessel of water.

"By Theorems deduced from this experiment, he infers, that the refraction of the rays of every sort, made out of any medium into air, are known by having the refraction of the rays of any one sort; and also, that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

"On the contrary, a Swedish philosopher, (M. Klingenshierna) observes *, that, in this experiment, the rays of light, after passing through the water and the glass, though they come out parallel to the incident rays, will be coloured; but that the smaller the glass prism is, the nearer will the result of it approach to Newton's description.

"This paper of M. Klingenshierna, being communicated to Mr Dollond by M. Mallet, made him entertain doubts concerning Newton's report of the result of his experiment; and determined him to have recourse to experiments of his own.

"He therefore cemented together two plates of parallel glass, at their edges, so as to form a prismatic vessel when stopped at the ends or bases; and the edge being turned downwards, he placed in it a glass prism with one of its edges upwards, and filled up the vacancy with clear water; so that the refraction of the prism was contrived to be contrary to that of the water, in order that a ray of light, transmitted through both these refracting mediums, might be affected by the difference only between the two refractions. As he found the water to refract more or less than the glass prism, he diminished or increased the angle between the glass plates, till he found the two contrary refractions to be equal, which he discovered by viewing an object through this double prism. For when it appeared neither raised nor depressed, he was satisfied that the refractions were equal, and that the emergent rays were parallel to the incident.

"Now, according to the prevailing opinion, he observes, that the object should have appeared through this double prism in its natural colour; for if the difference of refrangibility had been in all respects equal, in the two equal refractions, they would have rectified each other. But this experiment fully proved the fallacy of the received opinion, by shewing the divergency of the light by the glass prism to be almost double of that by the water; for the image of the object, though not at all refracted, was yet as much infected with prismatic colours, as though it had been seen through a glass wedge only whose angle was near 30 degrees.

"This experiment is the very same with that of Sir Isaac Newton above mentioned, notwithstanding the result was so remarkably different: but Mr Dollond assures us, that he used all possible precaution and care in his process; and he kept his apparatus by him, that he might evince the truth of what he wrote, whenever he should be properly required to do it.

"He plainly saw, however, that if the refracting angle of the water-vessel could have admitted of a sufficient increase, the divergency of the coloured rays would have been greatly diminished, or entirely rectified; and that there would have been a very great refraction without colour, as he had already produced a great discolouring without refraction: but the in-

* *Swed. Akad. vol. 16 p. 300.*

19 Colours produced without refraction or reflection.

17 Another theory of colours.

18 One of Sir Isaac Newton's experiments found to be false.

conveniency of so large an angle as that of the prismatic vessel must have been, to bring the light to an equal divergency with that of the glass prism, whose angle was about 60° , made it necessary to try some experiments of the same kind with smaller angles.

"Accordingly he got a wedge of plate-glass, the angle of which was only nine degrees; and, using it in the same circumstances, he increased the angle of the water-wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glass; that is, till the image of the object, though considerably refracted by the excess of the refraction of the water, appeared nevertheless quite free from any colours proceeding from the different refrangibility of the light.

"Notwithstanding it evidently appeared, I may say to almost all philosophers, that Mr Dollond had made a real discovery of something not comprehended in the optical principles of Sir Isaac Newton, it did not appear to be so sensible a man, and so good a mathematician, as Mr Murdoch is universally acknowledged to be. Upon this occasion he interposed in the defence, as he imagined, of Sir Isaac Newton; maintaining, that Mr Dollond's positions, which he says, he knows not by what mishap, have been deemed paradoxes in Sir Isaac's theory of light, are really the necessary consequences of it. He also endeavours to shew, that Sir Isaac might not be mistaken in his account of the experiment above mentioned. But admitting all that he advances in this part of his defence, Newton must have made use of a prism with a much smaller refracting angle than, from his own account of his experiments, we have any reason to believe he ever did make use of.

"The fact probably was, that Sir Isaac deceived himself in this case, by attending to what he imagined to be the clear consequences of his other experiments; and though the light he saw was certainly tinged with colours, and he must have seen it to be so, yet he might imagine that this circumstance arose from some imperfection in his prisms, or in the disposition of them, which he did not think it worth his while to examine. It is also observable, that Sir Isaac is not so particular in his description of his prisms, and other parts of his apparatus, in his account of this experiment, as he generally is in other cases, and therefore probably wrote his account of it from his memory only.

"Much has been said on this experiment; and it is thought very extraordinary that a man of Sir Isaac's accurate attention should overlook a circumstance, the effect of which now appears to be so considerable. But it has happily occurred to Mr Michell, that, as Sir Isaac Newton observes he used to put saccharum saturni into his water to increase its refractive power, the lead, even in this form, might increase the diffusive refraction, as it does in the composition of glass; and if so, that this would account for Newton's not finding the diffusive power of water less than that of his glass prisms, which he otherwise ought to have done, if he had tried the experiment as he said he did.

"Accordingly he included a prism of glass in water,

as highly impregnated with saccharum saturni as it would bear, the proportion of saccharum to water being about as 5 to 11. When the image, seen through the water (so impregnated) and a glass prism, was in its natural place, it still was coloured, though very little: he thought not more than a fourth part as much as when seen through plain water, and the prism in its natural place; so that he had no doubt, but that, if his prism had had a little less of the dispersing power, its errors would have been perfectly corrected."

From all these experiments we can only conclude that the theory of colours seems not yet to be determined with certainty; and very formidable, perhaps unanswerable, objections, might be brought against every hypothesis on this subject that hath been invented. The discoveries of Sir Isaac Newton, however, are sufficient to justify the following

21
Theory of
colours still
uncertain.

A P H O R I S M S.

1. All the colours in nature proceed from the rays of light.
2. There are seven primary colours; which are red, orange, yellow, green, blue, indigo, and violet.
3. Every ray of light may be separated into the seven primary colours.
4. The rays of light in passing through the same medium have different degrees of refrangibility.
5. The difference in the colours of light arises from its different refrangibility: that which is the least refrangible producing red; and that which is the most refrangible, violet.
6. By compounding any two of the primary colours, as red and yellow, or yellow and blue, the intermediate colour, as orange or green, may be produced.
7. The colours of bodies arise from their dispositions to reflect one sort of rays, and to absorb the other: those that reflect the least refrangible rays appearing red; and those that reflect the most refrangible, violet.
8. Such bodies as reflect two or more sorts of rays, appear of various colours.
9. The whiteness of bodies arises from their disposition to reflect all the rays of light promiscuously.
10. The blackness of bodies proceeds from their incapacity to reflect any of the rays of light*.

Entertaining EXPERIMENTS, founded on the preceding Principles.

- I. Out of a single colourless ray of light to produce seven other rays, which shall paint, on a white body, the seven primary colours of nature.

PROCEDURE of an optician a large glass prism DEF, Pl. lxxviii. well polished, two of whose sides must contain an angle of about sixty-four degrees. Make a room quite dark, and in the window shutter AB, cut a round hole, about one-third of an inch in diameter at C, through which a ray of light LI passing, falls on the prism DEF: by that it is refracted out of the direction IT, in which it would have proceeded into another GH; and, falling on the paper MNSX, will there form an oblong spectrum PQ, whose ends will be semicircular, and its sides straight; and if the distance of the

Fig. 1.

* From hence it arises that black bodies, when exposed to the sun, become sooner heated than all others.

the prism from the paper be about eighteen feet, it will be ten inches long, and two inches wide. This spectrum will exhibit all the primary colours: the rays between P and V, which are the most refracted, will paint a deep violet; those between V and I, indigo; those between I and B, blue; those between B and G, green; those between G and Y, yellow; those between Y and O, orange; and those between O and R, being the least refracted, an intense red. The colours between these spaces will not be every where equally intense, but will incline to the neighbouring colour: thus the part of the orange next to R, will incline to a red; that next to Y, to a yellow; and so of the rest.

II. *From two or more of the primary colours, to compose others that shall, in appearance, resemble those of the former.*

By mixing the two homogeneous colours red and yellow, an orange will be produced, similar in appearance to that in the series of primary colours; but the light of the one being homogeneous, and that of the other heterogonical, if the former be viewed through a prism it will remain unaltered, but the other will be resolved into its component colours red and yellow. In like manner other contiguous homogeneous colours may compound new colours; as by mixing yellow and green, a colour between them is formed; and if blue be added, there will appear a green that is the middle colour of those three. For the yellow and blue, if they are equal in quantity, will draw the intermediate green equally toward them, and keep it, as it were, in equilibrium, that it verge not more to the one than to the other. To this compound green there may be added some red and violet; and yet the green will not immediately cease, but grow less vivid; till by adding more red and violet it will become more diluted; and at last, by the prevalence of the added colours, it will be overcome, and turned into some anomalous colour.

If the sun's white, composed of all kind of rays, be added to any homogeneous colour, that colour will not vanish, nor change its species, but be diluted; and by adding more white, it will become continually more diluted. Lastly, if red and violet be mixed, there will be generated, according to their various proportions, various purples, such as are not like, in appearance, to the colour of any homogeneous light: and of these purples, mixed with blue and yellow, other new colours may be composed.

III. *Out of three of the primary colours, red, yellow, and blue, to produce all the other prismatic colours, and all that are intermediates to them.*

Fig. 2.

Provide three panes of glass of about five inches square; and divide each of them, by parallel lines; into five equal parts. Take three sheets of very thin paper; which you must paint, lightly, one blue, another yellow, and the third red*. Then paste on

one of the glasses five pieces of the red paper, one of which must cover the whole glass, the second only the four lower divisions, the third the three lower, the fourth the two lowest, and the fifth the last division only. On the other two glasses five pieces of the blue and yellow papers must be pasted in like manner. You must also have a box of about six inches long, and the same depth and width as the glasses: it must be black on the inside: let one end be quite open, and in the opposite end there must be a hole large enough to see the glasses completely. It must also open at the top, that the glasses may be placed in it conveniently.

When you have put any one of these glasses in the box, and the open end is turned toward the sun, you will see five distinct shades of the colour it contains. If you place the blue and yellow glasses together, in a similar direction, you will see five shades of green distinctly formed. When the blue and red glasses are placed, a bright violet will be produced; and by the red and yellow, the several shades of orange.

If, instead of placing these glasses in a similar position, you place the side AB of the yellow glass, against the side BD of the blue, you will see all the various greens that are produced by nature†; if the blue and red glasses be placed in that manner, you will have all the possible varieties of purples, violets, &c.; and lastly, if the red and orange glasses be so placed, there will be all the intermediate colours, as the magenta, aurora, &c.

Fig. 3.

IV. *By means of the three primary colours, red, yellow, and blue, together with light and shade, to produce all the gradations of the prismatic colours.*

On seven square pieces of glass paste papers that are painted with the seven prismatic colours, in the same manner as in the last experiment. The colours for the orange, green, indigo, and violet, may be made by mixing the other three. Then with bistre‡, well diluted, shade a sheet of very thin paper, by laying it light on both its sides. With pieces of this paper cover four-fifths of a glass, of the same size with the others, by laying one piece on the four lowest divisions, another on the three lowest, a third on the two lowest, and the fourth on the lowest division only; and leaving the top division quite uncovered. When one of the coloured glasses is placed in the box, together with the glass of shades, so that the side AB of the one be applied to the side BC of the other, as in fig. 3. the several gradations of colours will appear shaded in the same manner as a drapery judiciously painted with that colour.

It is on this principle that certain French artists have proceeded in their endeavours to imitate, by designs printed in colours, paintings in oil: which they do by four plates of the same size, on each of which is engraved the same design. One of these contains all the shades that are to be represented, and which are painted either black, or with a dark grey. One

* You must use water-colours for this purpose: the blue may be that of Prussia, and very bright; the red, carmine; and the yellow, gamboge, mixed with a little saffron. These colours must be laid very light and even, on both sides of the paper.

† In the first position of the glasses the quantity of blue and yellow being equal, the same sort of green was constantly visible, but by thus inverting the glasses, the quantity of the colours being constantly unequal, a very pleasing variety of tints is produced.

‡ The bistre here used must be made of foot, not that in stone.

One of the three other plates is coloured with blue, another with red, and the third with yellow; each of them being engraved in those parts only which are to represent that colour*, and the engraving is either stronger or weaker, in proportion to the tone of colour that is to be represented†.

These four plates are then passed alternately under the press, and the mixture of their colours produces a print that bears no small resemblance to a painting. It must be confessed, however, that what has been hitherto done of this kind falls far short of that degree of perfection of which this art appears susceptible. If they who engrave the best in the manner of the crayon were to apply themselves to this art, there is reason to expect they would produce far more finished pieces than we have hitherto seen.

V. *To make figures appear of different colours successively.*

Fig. 4.

MAKE a hole in the window-shutter of a dark room, through which a broad beam of light may pass, that is to be refracted by the large glass prism ABC, which may be made of pieces of mirrors cemented together, and filled with water. Provide another prism DEF, made of three pieces of wood; through the middle of this there must pass an axis on which it is to revolve. This prism must be covered with white paper; and each of its sides cut through in several places, so as to represent different figures, and those of each side should likewise be different. The inside of this prism is to be hollow, and made quite black, that it may not reflect any of the light that passes through the sides into it. When this prism is placed near to that of glass, as in the figure, with one of its sides EF perpendicular to the ray of light, the figures on that side will appear perfectly white: but when it comes into the position *g h*, the figures will appear yellow and red; and when it is in the position *k l*, they will appear blue and violet. As the prism is turned round its axis, the other sides will have a similar appearance. If instead of a prism a four or five sided figure be here used, the appearances will be still further diversified.

This phenomenon arises from the different refrangibility of the rays of light. For when the side EF is in the position *g h*, it is more strongly illuminated by the least refrangible rays; and wherever they are predominant, the object will appear red or yellow. But when it is on the position *k l*, the more refrangible rays being then predominant, it will appear tinged with blue and violet.

VI. *The solar magic lantern.*

PROCURE a box, of about a foot high, and 18 inches wide, or such other similar dimensions as you shall think fit; and about three inches deep. Two of

the opposite sides of this box must be quite open; and in each of the other sides let there be a groove, wide enough to pass a stiff paper or pasteboard. This box must be fastened against a window on which the sun's rays fall direct. The rest of the window should be closed up, that no light may enter. Provide several sheets of stiff paper, which must be blacked on one side. On these papers cut out such figures as you shall think proper; and placing them alternately in the grooves of the box, with their blacked sides towards you, look at them through a large and clear glass prism; and if the light be strong, they will appear to be painted with the most lively colours in nature. If you cut on one of these papers the form of the rainbow, about three quarters of an inch wide, you will have a lively representation of that in the atmosphere.

This experiment may be further diversified, by passing very thin papers, lightly painted with different colours, over some of the parts that are cut out: which will appear to change their colours, when viewed through the prism, and to stand out from the paper, at different distances, according to the different degrees of refrangibility of the colours with which they are painted. For greater convenience, the prism may be placed in a stand on a table, at the height of your eye, and made to turn round on an axis, that when you have got an agreeable prospect, you may fix in that position.

VII. *The prismatic camera obscura.*

MAKE two holes F, *f*, in the shutter of a dark chamber, near to each other; and against each hole place a prism ABC, and *a b c*, in a perpendicular direction, that their spectrums NM may be cast on the paper in a horizontal line, and coincide with each other; the red and violet of the one being in the same part with those of the other. The paper should be placed at such a distance from the prisms that the spectrum may be sufficiently dilated. Provide several papers nearly of the same dimensions with the spectrum, cross these papers, and draw lines parallel to the divisions of the colours. In these divisions cut out such figures as you shall find will have an agreeable effect, as flowers, trees, animals, &c. When you have placed one of these papers in its proper position, hang a black cloth or paper behind it, that none of the rays that pass through may be reflected and confuse the phenomenon. The figures cut on the paper will then appear strongly illuminated with all the original colours of nature. If while one of the prisms remains at rest, the other be revolved on its axis, the continual alteration of the colours will afford a pleasing variety; which may be further increased by turning the prism round in different directions.

When the prisms are so placed that the two spectrums become coincident in an inverted order of their colours,

Fig. 5.

* When a red drapery is required, it is engraved on the plate assigned to that colour; and so of yellow and blue: but if one of the other colours be wanting, suppose violet, it must be engraved on those that print the red and blue: and so of the rest. The plates of this kind have been hitherto engraved in the manner of mezzotint; but these, unless they are skillfully managed, soon become smutty. Engravings in the manner of the crayon, will perhaps answer better.

† The principal difficulty in this sort of engraving arises from want of a skillful management, in giving each plate that precise degree of engraving which will produce the tone of colour required. If a bright green is to be represented, there should be an equal quantity of graving on the red and yellow plates: but if an olive green, the yellow plate should be engraved much deeper than the red.

colours, the red end of one falling on the violet end of the other; if they be then viewed through a third prism *DH*, held parallel to their length, they will no longer appear coincident, but in the form of two distinct spectrums, *p t*, and *n m*, (fig. 6.) crossing one another in the middle, like the letter *X*: the red of one spectrum and the violet of the other, which were coincident at *NM*, being parted from each other by a greater refraction of the violet to *p*, and *m*, than that of the red to *n* and *t*.

This experiment may be further diversified by adding two other prisms, that shall form a spectrum in the same line, and contiguous to the other; by which not only the variety of figures, but the vicissitude of colours, will be considerably augmented.

VIII. The diatonic scale of colours.

THE illustrious Newton, in the course of his investigations of the properties of light, discovered that the length of the spaces which the seven primary colours possess in the spectrum, exactly corresponds to those of chords that sound the seven notes in the diatonic scale of music. As is evident by the following experiment.

Fig. 7.

On a paper in a dark chamber, let a ray of light be largely refracted into the spectrum *AFTMGF*, and mark the precise boundaries of the several colours, as *a, b, c, &c.* Draw lines from those points perpendicular to the opposite side, and you will find that the spaces *M r f f'*, by which the red is bounded; *r g e f*, by which the orange is bounded; *g p e d*, by which the yellow is bounded, &c. will be in exact proportion to the divisions of a musical chord for the notes of an octave; that is, as the intervals of these numbers $1, \frac{9}{8}, \frac{5}{4}, \frac{4}{3}, \frac{3}{2}, \frac{2}{1}$.

IX. Colorific music.

FATHER CASTEL, a Frenchman, in a curious book he has published on chromatics, supposes the note *ut* to answer to blue in the prismatic colours; the note *re* to yellow, and *mi* to red. The other tones he refers to the intermediate colours, from whence he constructs the following gamut of colorific music:

Ut	Blue
Ut sharp	Sea-green
Re	Bright green
Re sharp	Olive green
Mi	Yellow
Fa	Aurora
Fa sharp	Orange
Sol	Red
Sol sharp	Crimson
La	Violet
La sharp	Blue violet
Si	Sky blue
Ut	Blue

This gamut, according to his plan, is to be continued in the same manner for the following octave; except that the colours are to be more vivid.

He supposes that these colours, by striking the eye in the same succession as the sounds (to which he makes them analogous) do the ear, and in the same order of time, they will produce a correspondent sensation of

pleasure in the mind. It is on these general principles, which F. Castel has dilucidated in his treatise, that he has endeavoured, though with little success, to establish his ocular harpsichord.

The construction of this instrument, as here explained, will show that the effects produced by colours by no means answer those of sounds, and that the principal relation there is between them consists in the duration of the time that they respectively affect the senses.

Between two circles of pasteboard, of ten inches diameter, *AB* and *CD*, inclose a hollow pasteboard cylinder *E*, 18 inches long. Divide this cylinder into spaces half an inch wide, by a spiral line that runs round it from top to bottom, and divide its surface into six equal parts by parallel lines drawn between its two extremities; as is expressed in the figure.

Fig. 8.

Let the circle *AB*, at top, be open; and let that at bottom, *CD*, be closed, and supported by an axis or screw, of half an inch diameter, which must turn freely in a nut placed at the bottom of a box we shall presently describe. To the axis just mentioned adjust a wooden wheel *G*, of two inches and a half in diameter, and that has 12 or 15 teeth, which take the endless screw *H*. Let this cylinder be inclosed in a box *ILMN* (fig. 9.) whose base is square, and at whose bottom there is a nut in which the axis *F* turns. Observe that the endless screw *H*, should come out of the box, that it may receive the handle *O*, by which the cylinder is to be turned.

This box being closed all round, place over it a tin covering *A*, which must be perforated in different parts; from this cover there must hang three or four lights, so placed that they may strongly illumine the inside of the cylinder. In one side of this box (which should be covered with pasteboard) cut eight apertures, *a, b, c, d, e, f, g, h*, of half an inch wide, and $\frac{1}{2}$ of an inch high; they must be directly over each other, and the distance between them must be exactly two inches. It is by these openings, which here correspond to the musical notes, that the various colours analogous to them are to appear; and which being placed on the pasteboard cylinder, as we have shown, are reflected by means of the lights placed within it.

Fig. 9.

It is easy to conceive, that when the handle *O* is turned, the cylinder in consequence rising half an inch, if it be turned five times round, it will successively show, at the openings made in the side of the box, all those that are in the cylinder itself, and which are ranged according to the direction of the inclined lines drawn on it. It is therefore according to the duration of the notes which are to be expressed, that the apertures on the cylinder are to be cut. Observe, that the space between two of the parallel lines drawn vertically on the cylinder, is equal to one measure of time; therefore, for every turn of the cylinder, there are six measures, and thirty measures for the air that is to be played by this instrument.

The several apertures being made in the side of the cylinder, in conformity to the notes of the tune that is to be expressed, they are to be covered with double pieces of very thin paper, painted on both sides with the colours that are to represent the musical notes.

This.

This experiment might be executed in a different manner, and with a much greater extent; but as the entertainment would not equal the trouble and ex-

pence, we have thought it sufficient to give the above piece, by which the reader will be enabled to judge how far the analogy supposed by F. Castet really exists.

CHRONIC, or CHRONICAL, among physicians, an appellation given to diseases that continue a long time; in contradistinction to those that soon terminate, and are called *acute*.

CHRONICLE, in matters of literature, a species or kind of history disposed according to the order of time, and agreeing in most respects with annals. See ANNALS.

Books of CHRONICLES, a canonical writing of the Old Testament. It is uncertain which were written first, *The Books of Kings*, or *The Chronicles*, since they each refer to the other. However it be, the latter is often more full and comprehensive than the former. Whence the Greek interpreters call these two books *Παραπομπαι*, *Supplements*, *Additions*, because they contain some circumstances which are omitted in the other historical books. The Jews make but one book of the Chronicles, under the title of *Dibre-Haiaimim*, i. e. *Journals* or *Annals*. Ezra is generally believed to be the author of these books. It is certain they were written after the end of the Babylonish capti-

vity, and the first year of the reign of Cyrus, of whom mention is made in the last chapter of the second book.

The *Chronicles*, or *Paraleipomena*, are an abridgement of all the sacred history, from the beginning of the Jewish nation to their first return from the captivity, taken out of those books of the Bible which we still have, and out of other annals which the author had then by him. The design of the writer was to give the Jews a series of their history. The first book relates the rise and propagation of the people of Israel from Adam, and gives a punctual and exact account of the reign of David. The second book sets down the progress and end of the kingdom of Judah, to the very year of their return from the Babylonish captivity.

CHRONOGRAM, a species of false wit, consisting in this, that a certain date or epocha is expressed by numeral letters of one or more verses; such is that which makes the motto of a medal struck by Gustavus Adolphus in 1632:

ChrIRV DVX; ergo trIVMphVs.

C H R O N O L O G Y

IS the science that teaches the method of measuring time and distinguishing its parts. It is more difficult, than may at first appear, to determine the precise idea, and clearly to explain the nature, of time. That ingenious and subtle impostor Mahomet has given in his Alcoran some traces of very refined ideas of this subject. But, leaving these metaphysical researches, we shall content ourselves with saying, that by *time* we here mean the duration and succession of created beings. To determine a fixed and sensible measure of duration, it is necessary to find some motion that is constantly uniform, which may serve as a scale for that measure. From the creation of the world, it has been observed that the courses of the heavenly bodies afford the most universal measure of motion to all the inhabitants of the earth. As it was originally imagined that the sun turned round the earth, his annual and diurnal revolutions were fixed on for the common measure of time; and by this measure they divided the duration of beings into years, months, weeks, days, hours, minutes, and seconds. It may seem strange to an astronomer, or chronologist, to read, in the first chapter of Genesis, that God did not create the sun, moon, and stars, till the fourth day, and that there were days and nights before there was any sun. But who can say what is there precisely meant by the word *day*? Moses, who lived about 3000 years after the creation, wrote the origin and history of the Jews. In order to which, he recurred to the origin of all things: he began with the creation itself: but he wrote to men; and to men who were even less enlightened than we are, especially in matters of astronomy. He was,

therefore, obliged to make use of expressions that were to them intelligible. The scriptures were moreover given to mankind to serve them as guides in matters of religion, and not to teach them astronomy; of which were they ignorant, they would be obliged to believe, for example, that the sun moves round the earth, and that it was stopped, though a thousand times greater than the whole terrestrial globe, by the desire of Joshua at Gibeon; and that the moon halted in the valley of Ajalon, &c.: all which is directly contrary to the eternal laws of nature, and therefore, taken in the strict letter, cannot be true. But who knows what means Providence may have employed to produce these appearances? Without making further inquiry into these matters, let us acknowledge the goodness of the Holy Spirit that has vouchsafed to speak to mankind in a language adapted to their capacities, in pointing out the path that leads to eternal felicity; where those dark clouds which now surround the human understanding shall be dispersed, and it will then perhaps discover many of those positions to be errors which philosophers and astronomers now regard as axioms or incontestable truths.

The term *chronology*, when taken in its full extent, has two objects: the first is the measuring of time and its different divisions. This part of chronology is regulated by astronomical calculation, and consequently makes a part of mathematics; and it is by this method that we are enabled to make complete calendars or almanacs. The second part of chronology consists in fixing the dates of all those events that are related in history, and of ranging them in the several divisions of time in which they occurred: and by this means

means chronology becomes one of the essential parts of history. This second part draws its principles from the first; but it has need of other supports, as of criticism, of the testimony of authors, of ancient coins, medals, inscriptions, &c. of such epochs in history as are incontestable; of eclipses of the sun and moon, and other astronomical observations, &c. The subject of the *first* part has been treated under *ASTRONOMY*. That of the *second* falls to be considered in the present article.

OF HISTORIC CHRONOLOGY.

It is in this science that Julius Africanus, Eusebius of Casarea, George Cynelle, John of Antioch, Denis, Petau, Cluvier, Calvisius, Uher, Simfon, John Marsham, and many other learned men, have excelled. It consists of four principal parts, that form the foundations on which all its learned researches rest. These are,

1. Astronomic observations, and particularly on the eclipses of the sun and moon, combined with the calculations of mathematic chronology on the different eras and years of different nations.
2. The testimonies of credible authors.
3. Those epochs in history which are so determined and evident that no one has ever contested them.
4. Ancient medals, coins, monuments, and inscriptions.

We shall examine these four principal parts in the order they here stand; and conclude with some reflections on the uncertainty that still reigns, notwithstanding these lights, in chronological history.

I.

It is with great reason that the eclipses of the sun, and moon, and the aspects of the other planets, have been called public and celestial characters of the times, as their calculations afford chronologers infallible proofs of the precise epochs in which a great number of the most signal events in history have occurred. So that in chronological matters we cannot make any great progress, if we are ignorant of the use of astronomic tables, and the calculation of eclipses. The ancients regarded the latter as prognostics of the fall of empires, of the loss of battles, of the death of monarchs, &c. And it is to this superstition, to this wretched ignorance, that we happily owe the vast labour that historians have taken to record so great a number of them. The most able chronologers have collected them with still greater labour. Calvisius, for example, finds his chronology on 144 eclipses of the sun, and 127 of the moon, that he says he had calculated. The grand conjunction of the two superior planets, Saturn and Jupiter, which, according to Kepler, occurs once in 800 years in the same point of the zodiac, and which has happened only eight times since the creation, (the last time in the month of December 1603), may also furnish chronology with incontestable proofs. The same may be said of the transit of Venus over the sun, which has been observed in our days, and all the other uncommon positions of the planets. But among these celestial and natural characters of times, there are also some that are named *civil* or *artificial*, and which, nevertheless, depend on astronomic calculation.

Vol. III.

Such are the solar and lunar cycles; the Roman indiction; the feast of Easter; the bissextile year; the jubilees; the sabbatic years; the combats and Olympic games of the Greeks; and heira of the Mahometans, &c. And to these may be added the periods, eras, epochs, and years of different nations, ancient and modern. We shall only remark on this occasion, that the period or era of the Jews commences with the creation of the world; that of the ancient Romans with the foundation of the city of Rome; that of the Greeks at the establishment of the Olympic games; that of Nebuchadnezzar, with the advancement of the first king of Babylon to the throne; the Yezdegerdic years, with the last king of the Persians of that name; the heira of the Turks with the flight of Mahomet from Mecca to Medina, &c. The year of the birth of Christ was the 4713th year of the Julian period, according to the common method of reckoning. Astronomical chronology teaches us to calculate the precise year of the Julian period in which each of these epochs happened. See *ASTRONOMY*, Sect. xii.

II.

THE testimony of authors is the second principal part of historic chronology. Though no man whatever has a right to pretend to infallibility, or to be regarded as a sacred oracle, it would, however, be making a very unjust judgment of mankind, to treat them all as dupes or impostors; and it would be an injury offered to public integrity, were we to doubt the veracity of authors universally esteemed, and of facts that are in themselves right worthy of belief. It would be even a kind of infatuation to doubt that there have been such cities as Athens, Sparta, Rome, Carthage, &c. or that Xerxes reigned in Persia, and Augustus in Rome; whether Hannibal ever was in Italy; or that the emperor Constantine built Constantinople, &c. The unanimous testimony of the most respectable historians will not admit any doubt of these matters. When an historian is allowed to be completely able to judge of an event, and to have no intent of deceiving by his relation, his testimony is irrefutable. But to avoid the danger of adopting error for truth, and to be satisfied of a fact that appears doubtful in history, we may make use of the four following rules, as they are founded in reason.

1. We ought to pay a particular regard to the testimonies of those who wrote at the same time the events happened, and that have not been contradicted by any cotemporary author of known authority. Who can doubt, for example, of the truth of the facts related by admiral Anfon, in the history of his voyage round the world? The admiral saw all the facts there mentioned with his own eyes, and published his book when two hundred companions of his voyage were still living in London, and could have contradicted him immediately, if he had given any false or exaggerated relations.

2. After the cotemporary authors, we should give more credit to those who lived near the time the events happened, than those who lived at a distance.

3. Those doubtful histories, which are related by authors that are but little known, can have no weight

if they are at variance with reason, or established tradition.

4. We must distrust the truth of a history that is related by modern authors, when they do not agree among themselves in several circumstances, nor with ancient historians, who are to be regarded as original sources. We should especially doubt the truth of those brilliant portraits, that are drawn at pleasure by such as never knew the persons they are intended for, and even made several centuries after their decease.

The most pure and most fruitful source of ancient history is doubtless to be found in the Holy Bible. Let us here for a moment cease to regard it as divine, and let us presume to consider it as a common history. Now, when we regard the writers of the books of the Old Testament, and consider them sometimes as authors, sometimes as ocular witnesses, and sometimes as respectable historians; whether we reflect on the simplicity of the narration, and the air of truth that is there constantly visible; or, when we consider the care that the people, the governments, and the learned men of all ages have taken to preserve the true text of the Bible; or that we have regard to the happy conformity of the chronology of the Holy Scriptures with that of prophane history; or, if we observe the admirable harmony that is between these books and the most respectable historians, as Josephus and others; and lastly, when we consider that the books of the holy scripture furnish us alone with an accurate history of the world from the creation, through the line of patriarchs, judges, kings and princes of the Hebrews; and that we may, by its aid, form an almost entire series of events down to the birth of Christ, or the time of Augustus, which comprehends a space of about 4000 years, some small interruptions excepted, and which are easily supplied by profane history: when all these reflections are justly made, we must constantly allow that the scriptures form a book which merits the first rank among all the sources of ancient history. It has been objected, that this book contains contradictions; but the most able interpreters have reconciled these seeming contradictions. It has been said, that the chronology of the Hebrew text and the Vulgate, do not agree with the chronology of the version of the Septuagint; but the soundest critics have shown that they may be made to agree. It has been observed, moreover, that the scriptures abound with miracles and prodigies; but they are miracles that have really happened: and what ancient history is there that is not filled with miracles and other marvellous events? And do we for that reject their authority? Cannot the true God be supposed to have performed those miracles which Pagan historians have attributed to their false divinities? Must we pay no regard to the writings of Livy, because his history contains many fabulous relations?

III.

THE *epochs* form the third principal part of chronology. These are those fixed points in history that have never been contested, and of which there can, in fact, be no doubt. Chronologers fix on the events that are to serve as epochs, in a manner quite arbitrary;

but this is of little consequence, provided the dates of these epochs agree, and that there is no contradiction in the facts themselves. When we come to treat expressly on history, we shall mention, in our progress, all the principal epochs.

IV.

MEDALS, monuments, and inscriptions, form the fourth and last principal part of chronology. It is scarce more than 150 years since close application has been made to the study of these; and we owe to the celebrated Spanheim the greatest obligations, for the progress that is made in this method; his excellent work, *De præstantia et usu numismatum antiquorum*, has shown the great advantages of it; and it is evident that these monuments are the most authentic witnesses that can be produced. It is by the aid of medals that M. Vaillant has composed his judicious history of the kings of Syria, from the time of Alexander the Great to that of Pompey: they have been, moreover, of the greatest service in elucidating all ancient history, especially that of the Romans; and even sometimes that of the middle age. Their use is more fully spoken of in the article MEDALS. What we here say of medals, is to be understood equally, in its full force, of ancient inscriptions, and of all other authentic monuments that have come down to us: as the famous *Arun del marbles*, which the earl of Arundel (from whom they have been denominated) purchased from the Turks in the Levant, by William Petre, whom he sent thither for that purpose. These marbles, which were ranged at London in the rooms and garden of that nobleman, on the border of the Thames, were found in the island of Paros; and contain a chronicle, wherein the principal epochs of the history of the Athenians are exactly and distinctly marked, from the first year of the reign of Cecrops, which began 1582 years before the Christian era. John Selden composed a book in 1629, the title of which is *Marmora Arundelliana*, wherein he explains these valuable antiquities.

Every reader, endowed with a just discernment, will readily allow that these four parts of chronology afford clear lights, and are excellent guides to conduct us through the thick darkness of antiquity. That impartiality, however, which directs us to give a faithful relation of that which is true and false, of the certainty and uncertainty of all the sciences, obliges us here freely to confess, that these guides are not infallible, nor the proofs that they afford mathematical demonstrations. In fact, with regard to history in general, and ancient history in particular, something must be always left to conjecture and historic faith. It would be an offence against common probity, were we to suffer ourselves to pass over in silence those objections which authors of the greatest reputation have made against the certainty of chronology. We shall extract them from their own works; and we hope that there is no magistrate, theologian, or public professor in Europe, who would be mean enough to accuse us of a crime, for not unworthily disguising the truth.

1. The prodigious difference there is between the Septuagint Bible and the Vulgate, in point of chronology,

Bisfield's
Elements.

logy, occasions an embarrassment, which is the more difficult to avoid, as we cannot positively say on which side the error lies. The Greek Bible counts, for example, from the creation of the world to the birth of Abraham, 1500 years more than the Hebrew and Latin Bibles, &c. 2. How difficult is it to ascertain the years of the judges of the Jewish nation, in the Bible? What darkness is spread over the succession of the kings of Judah and Israel? The calculation of time is there so inaccurate, that the scripture never marks if they are current or complete years. For we cannot suppose that a patriarch, judge, or king, lived exactly 60, 90, 100, or 999 years, without any odd months or days. 3. The different names that the Assyrians, Egyptians, Persians, and Greeks, have given to the same prince, have contributed not a little to embarrass all ancient chronology. Three or four princes have borne the name of Assuerus, though they had also other names. If we did not know that Nabucodonosor, Nabucodrosor, and Nabucolassar, were the same name, or the name of the same man, we should scarcely believe it. Sargon is Sennacherib; Ozias is Azarias; Sedecias is Marhanias; Joachas is also called Sellum; Adaraddon, which is pronounced indifferently Esarhaddon and Afarhaddon, is called Asenaphar by the Cuthians; and by an oddity of which we do not know the origin, Sardanapalus is called by the Greeks Tenos Concoleros. 4. There remain to us but few monuments of the first monarchs of the world. Numberless books have been lost, and those which have come down to us are mutilated or altered by transcribers. The Greeks began to write very late. Herodotus, their first historian, was of a credulous disposition, and believed all the fables that were related by the Egyptian priests. The Greeks were in general vain, partial, and held no nation in esteem but their own. The Romans were still more infatuated with notions of their own merit and grandeur: their historians were altogether as unjust as was their senate, toward other nations that were frequently far more respectable. 5. The eras, the years, the periods and epochs, were not the same in each nation; and they, moreover, began at different seasons of the year. All this has thrown so much obscurity over chronology, that it appears to be beyond all human capacity totally to disperse it.

Christianity itself had subsisted near 1200 years, before they knew precisely how many years had passed since the birth of our Saviour. They saw clearly that the vulgar era was defective, but it was a long time before they could comprehend that it required four whole years to make up the true period. Abbé Denis the Little, who, in the year 532, was the first among the Christians, to form the era of that grand epoch, and to count the years from that time, in order to make their chronology altogether Christian, erred in his calculation, and led all Europe into his error. They count 132 contrary opinions of different authors concerning the year in which the Messiah appeared on the earth. M. Vallemont names 64 of them, and all celebrated writers. Among all these authors, however, there is none that reckon more than 7000, nor less than 3700 years. But even this difference is enormous. The most moderate fix the

birth of Christ in the 4000th year of the world. The reasons, however, on which they found their opinion, appear to be sufficiently arbitrary.

Be these matters, however, as they may, the wisdom of Providence has so disposed all things, that there remain sufficient lights to enable us nearly to connect the series of events: for in the first 3000 years of the world, where profane history is defective, we have the chronology of the Bible to direct us; and after that period, where we find more obscurity in the chronology of the holy scriptures, we have, on the other hand, greater lights from profane authors. It is at this period that begin the time which Varro calls *historicæ*: as, since the time of the Olympiads, the truth of such events as have happened shines clear in history. Chronology, therefore, draws its principal lights from history; and, in return, serves it as a guide. Referring the reader, therefore, to the article HISTORY, and the *Chart* thereto annexed, we shall conclude the present article with

A CHRONOLOGICAL TABLE of Remarkable Events, Discoveries, and Inventions, from the Creation to the present Time.

BEF. CHRIST.

4004 THE creation of the world, and Adam and Eve.
4003 The birth of Cain, the first who was born of a woman.

3017 Enoch, for his piety, is translated to Heaven.

2348 The old world is destroyed by a deluge which continued 377 days.

2247 The Tower of Babel is built about this time by Noah's posterity, upon which God miraculously confounds their language, and thus disperses them into different nations.

About the same time, Noah is, with great probability, supposed to have parted from his rebellious offspring, and to have led a colony of some of the more tractable into the east, and there either he or one of his successors to have founded the ancient Chinese monarchy.

2234 The celestial observations are begun at Babylon, the city which first gave birth to learning and the sciences.

2188 Misraim, the son of Ham, founds the kingdom of Egypt, which lasted 1663 years, down to the conquest of Cambyfes, in 525 before Christ.

2059 Ninus, the son of Belus, founds the kingdom of Assyria, which lasted above 1000 years, and out of its ruins were formed the Assyrians of Babylon, those of Nineveh, and the kingdom of the Medes.

1921 The covenant of God made with Abram, when he leaves Haran to go into Canaan, which begins the 430 years of sojourning.

1897 The cities of Sodom and Gomora are destroyed for their wickedness, by fire from heaven.

1856 The kingdom of Argos, in Greece, begins under Inachus.

1822 Memnon, the Egyptian, invents the letters.

1715 Prometheus first struck fire from flints.

1635 Joseph dies in Egypt, which concludes the book of Genesis, containing a period of 2369 years.

Bef. Christ.

- 1574 Aaron born in Egypt; 1490, appointed by God first high-priest of the Israelites.
- 1571 Moses, brother to Aaron, born in Egypt, and adopted by Pharaoh's daughter, who educates him in all the learning of the Egyptians.
- 1556 Cecrops, brings a colony of Saïtes from Egypt into Attica, and begins the kingdom of Athens in Greece.
- 1546 Scamander comes from Crete into Phrygia, and begins the kingdom of Troy.
- 1493 Cadmus carried the Phenician letters into Greece, and built the citadel of Thebes.
- 1491 Moses performs a number of miracles in Egypt, and departs from that kingdom, together with 600,000 Israelites, besides children, which completed the 430 years of sojourning. They miraculously pass through the Red Sea, and come to the desert of Sinai, where Moses receives from God, and delivers to the people, the Ten Commandments, and the other laws, and sets up the tabernacle, and in it the ark of the covenant.
- 1485 The first ship that appeared in Greece, was brought from Egypt by Danaus, who arrived at Rhodes, and brought with him his fifty daughters.
- 1453 The first Olympic games celebrated at Olympia in Greece.
- 1452 The Pentateuch, or five first books of Moses, are written in the land of Moab, where he died the year following, aged 110.
- 1451 The Israelites, after sojourning in the Wilderness forty years, and led under Joshua into the land of Canaan, where they fix themselves, after having subdued the natives; and the period of the sabbatical year commences.
- 1406 Iron is found in Greece, from the accidental burning of the woods.
- 1198 The rape of Helen by Paris, which, in 1193, gave rise to the Trojan war, and siege of Troy, by the Greeks, which continued ten years, when that city was taken and burnt.
- 1048 David is sole king of Israel.
- 1004 The Temple is solemnly dedicated by Solomon.
- 896 Elijah, the prophet, is translated to Heaven.
- 894 Money first made of gold and silver at Argos.
- 869 The city of Carthage, in Africa, founded by queen Dido.
- 814 The kingdom of Macedon begins.
- 753 Æra of the building of Rome in Italy by Romulus, first king of the Romans.
- 720 Samaria taken, after three years siege, and the kingdom of Israel finished, by Salmanassar, king of Assyria, who carries the ten tribes into captivity.
- The first eclipse of the moon on record.
- 658 Byzantium (now Constantinople) built by a colony of Athenians.
- 604 By order of Necho, king of Egypt, some Phenicians sailed from the Red Sea round Africa, and returned by the Mediterranean.
- 600 Thales, of Miletus, travels into Egypt, consults the priests of Memphis, acquires the knowledge of geometry, astronomy, and philoso-

phy; returns to Greece, calculates eclipses, gives general notions of the universe, and maintains that an only supreme Intelligence regulates all its motions.

Bef. Christ.

- Maps, globes, and the signs of the Zodiac, invented by Anaximander, the scholar of Thales.
- 597 Jehoiakin, king of Judah, is carried away captive, by Nebuchadnezzar, to Babylon.
- 587 The city of Jerusalem taken, after a siege of 18 months.
- 562 The first comedy at Athens acted upon a moveable scaffold.
- 559 Cyrus the first king of Persia.
- 538 The kingdom of Babylon finished; that city being taken by Cyrus, who, in 536, gives an edict for the return of the Jews.
- 535 The first tragedy was acted at Athens, on a waggon, by Thespis.
- 526 Learning is greatly encouraged at Athens, and a public library first founded.
- 515 The second temple at Jerusalem is finished under Darius.
- 509 Tarquin, the seventh and last king of the Romans, is expelled, and Rome is governed by two consuls, and other republican magistrates, till the battle of Pharsalia, being a space of 461 years.
- 504 Sardis taken and burnt by the Athenians, which gave occasion to the Persian invasion of Greece.
- 486 Æschylus, the Greek poet, first gains the prize of tragedy.
- 481 Xerxes the Great, king of Persia, begins his expedition against Greece.
- 458 Ezra is sent from Babylon to Jerusalem, with the captive Jews and the vessels of gold and silver, &c. being seventy weeks of years, or 490 years before the crucifixion of our Saviour.
- 454 The Romans send to Athens for Solon's laws.
- 451 The Decemvirs created at Rome, and the laws of the twelve tables compiled and ratified.
- 430 The history of the Old Testament finishes about this time.
- Malachi the last of the prophets.
- 400 Socrates, the founder of moral philosophy among the Greeks, believes the immortality of the soul, a state of rewards and punishments; for which, and other sublime doctrines, he is put to death by the Athenians, who soon after repent, and erect to his memory a statue of brass.
- 331 Alexander the Great, king of Macedon, conquers Darius, king of Persia, and other nations of Asia. 323, Dies at Babylon, and his empire is divided by his generals into four kingdoms.
- 285 Dionysius, of Alexandria, began his astronomical æra on Monday June 26, being the first who found the exact solar year to consist of 365 days, 5 hours, and 49 minutes.
- 284 Ptolemy Philadelphus, king of Egypt, employs 72 interpreters to translate the Old Testament into the Greek language, which is called the Septuagint.
- 269 The first coining of silver at Rome.
- 264 The first Punic war begins, and continues 23 years.

years. The chronology of the Arundelian marbles composed.

- 260 The Romans first concern themselves in naval affairs, and defeat the Carthaginians at sea.
- 237 Hamilcar, the Carthaginian, causes his son Hannibal, at nine years old, to swear eternal enmity to the Romans.
- 218 The second Punic war begins, and continues 17 years. Hannibal passes the Alps, and defeats the Romans in several battles; but being amused by his women, does not improve his victories by the storming of Rome.
- 190 The first Roman army enters Asia, and from the spoils of Antiochus brings the Asiatic luxury first to Rome.
- 168 Perseus defeated by the Romans, which ends the Macedonian kingdom.
- 167 The first library erected at Rome, of books brought from Macedonia.
- 163 The government of Judea under the Maccabees begins, and continues 126 years.
- 146 Carthage, the rival to Rome, is razed to the ground by the Romans.
- 135 The history of the Apocrypha ends.
- 52 Julius Cæsar makes his first expedition into Britain.
- 47 The battle of Pharfalia, between Cæsar and Pompey, in which the latter is defeated. The Alexandrian library, consisting of 400,000 valuable books, burnt by accident.
- 45 The war of Africa, in which Cato kills himself. The solar year introduced by Cæsar.
- 44 Cæsar, the greatest of the Roman conquerors, after having fought fifty pitched battles, and slain 1,192,000 men, is killed in the senate-house by conspirators.
- 31 The battle of Actium fought, in which Mark Anthony and Cleopatra are totally defeated by Octavius, nephew to Julius Cæsar.
- 30 Alexandria, in Egypt, is taken by Octavius, upon which Anthony and Cleopatra put themselves to death, and Egypt is reduced to a Roman province.
- 27 Octavius, by a decree of the senate, obtains the title of Augustus Cæsar, and an absolute exemption from the laws, and is properly the first Roman emperor.
- 8 Rome at this time is fifty miles in circumference, and contains 463,000 men fit to bear arms.
The temple of Janus is shut by Augustus, as an emblem of universal peace, and
JESUS CHRIST is born, on Monday, December 25.
- 12 — Disputes with the Doctors in the Temple;
- 27 — is baptized in the wilderness by John,
- 33 — and crucified on Friday, April 3. at 3 o'clock P. M. his resurrection on Sunday, April 5; his Ascension, Thursday May 14.
- 26 St Paul converted.
- 39 St Matthew writes his Gospel.
Pontius Pilate kills himself.
- 40 The name of Christians first given at Antioch to the followers of Christ.

- 43 Claudius Cæsar's expedition into Britain.
- 44 St Mark writes his Gospel.
- 49 London is founded by the Romans; 368, surrounded by ditto with a wall, some parts of which are still observable.
- 51 Caractacus, the British king, is carried in chains to Rome.
- 52 The council of the Apostles at Jerusalem.
- 55 St Luke writes his gospel.
- 59 The emperor Nero puts his mother and brothers to death.
— Persecutes the Druids in Britain.
- 61 Boadicea, the British queen, defeats the Romans; but is conquered soon after by Suetonius, governor of Britain.
- 62 St Paul is sent in bonds to Rome—writes his epistles between 51 and 66.
- 63 The Acts of the Apostles written.
Christianity is supposed to be introduced into Britain by St Paul or some of his disciples about this time.
- 64 Rome set on fire, and burned for six days; upon which began (under Nero) the first persecution against the Christians.
- 67 St Peter and St Paul put to death.
- 70 While the factious Jews are destroying one another with mutual fury, Titus, the Roman general, takes Jerusalem, which is razed to the ground, and the plough made to pass over it.
- 83 The philosophers expelled Rome by Domitian.
- 85 Julius Agricola, governor of South-Britain, to protect the civilized Britains from the incursions of the Caledonians, builds a line of forts between the rivers Forth and Clyde; defeats the Caledonians under Calgacus on the Grampian hills; and first sails round Britain, which he discovers to be an island.
- 96 St John the evangelist wrote his Revelation—his Gospel in 97.
- 121 The Caledonians reconquer from the Romans all the southern parts of Scotland; upon which the emperor Adrian builds a wall between Newcastle and Carlisle; but this also proving ineffectual, Pollius Urbicus, the Roman general, about the year 144, repairs Agricola's forts which he joins by a wall four yards thick.
- 135 The second Jewish war ends, when they were all banished Judea.
- 139 Justin writes his first Apology for the Christians.
- 141 A number of heresies appear about this time.
- 152 The emperor Antoninus Pius stops the persecution against the Christians.
- 217 The Septuagint found in a cask.
- 222 About this time the Roman empire begins to sink under its own weight. The Barbarians begin their eruptions, and the Goths have annual tribute not to molest the empire.
- 260 Valerius is taken prisoner by Sapor, king of Persia, and dead alive.
- 274 Silk first brought from India; the manufactory of it introduced into Europe by some monks, 551; first worn by the clergy in England, 1534.
- 291 Two emperors and two Cæsars march to defend the

- the four quarters of the empire.
- 306 Constantine the Great begins his reign.
- 308 Cardinals first began.
- 313 The tenth persecution ends by an edict of Constantine, who favours the Christians, and gives full liberty to their religion.
- 314 Three bishops, or fathers, are sent from Britain to assist at the council of Arles.
- 325 The first general council at Nice, when 318 fathers attended, against Arius, the founder of Arianism, where was composed the famous Nicene Creed, which we attribute to them.
- 328 Constantine removes the seat of empire from Rome to Byzantium, which is thereafter called Constantinople.
- 331 ——— orders all the heathen temples to be destroyed.
- 363 The Roman emperor Julian, surnamed the Apostate, endeavours in vain to rebuild the temple of Jerusalem.
- 364 The Roman empire is divided into the eastern (Constantinople the capital) and western, (of which Rome continued to be the capital), each being now under the government of different emperors.
- 400 Bells invented by bishop Paulinus, of Campagna.
- 404 The kingdom of Caledonia or Scotland revives under Fergus.
- 406 The Vandals, Alans, and Suevi, spread into France and Spain, by a concession of Honorius, emperor of the West.
- 410 Rome taken and plundered by Alaric, king of the Visi-Goths.
- 412 The Vandals begin their kingdom in Spain.
- 420 The kingdom of France begins upon the Lower Rhine, under Pharamond.
- 426 The Romans, reduced to extremities at home, withdraw their troops from Britain, and never return; advising the Britons to arm in their own defence, and trust to their own valour.
- 446 The Britons, now left to themselves, are greatly harassed by the Scots and Picts, upon which they once more make their complaint to the Romans, (which they entitle, *The Complaints of the Britons*), but receive no assistance from that quarter.
- 447 Attila (surnamed the Scourge of God) with his Huns ravage the Roman empire.
- 449 Vortigern, king of the Britons, invites the Saxons into Britain, against the Scots and Picts.
- 455 The Saxons having repulsed the Scots and Picts invite over more of their countrymen, and begin to establish themselves in Kent, under Hengist.
- 476 The western empire is finished, 523 years after the battle of Pharsalia; upon the ruins of which several new states arise in Italy and other parts, consisting of Goths, Vandals, Huns, and other barbarians, under whom literature is extinguished, and the works of the learned are destroyed.
- 496 Clovis, king of France, baptized, and Christianity begins in that kingdom.
- 508 Prince Arthur begins his reign over the Britons.
- 513 Constantinople besieged by Vitalianus, whose fleet is burnt by a speculum of brass.
- 516 The computing of time by the Christian era is introduced by Dionysius the monk.
- 529 The codex of Justinian, the eastern emperor, is published.
- 557 A terrible plague all over Europe, Asia, and Africa, which continues near fifty years.
- 581 Latin ceased to be spoke about this time in Italy.
- 596 Augustin the monk comes into England with forty monks.
- 606 Here begins the power of the popes, by the concessions of Phocas, emperor of the East.
- 622 Mahomet, the false prophet, flies from Mecca to Medina, in Arabia, in the 44th year of his age, and 10th of his ministry, when he laid the foundation of the Saracen empire, and from whom the Mahometan princes to this day claim their descent. His followers compute their time from this era, which in Arabic is called *hegira*, i. e. "the Flight."
- 637 Jerusalem is taken by the Saracens or followers of Mahomet.
- 640 Alexandria in Egypt is taken by ditto, and the grand library there burnt by order of Omar their caliph or prince.
- 653 The Saracens now extend their conquests on every side, and retaliate the barbarities of the Goths and Vandals upon their posterity.
- 664 Glass invented in England by Benet a monk.
- 685 The Britons, after a brave struggle of near 150 years, are totally expelled by the Saxons, and drove into Wales and Cornwall.
- 713 The Saracens conquer Spain.
- 726 The controversy about images begins, and occasions many insurrections in the eastern empire.
- 748 The computing of years from the birth of Christ began to be used in history.
- 749 The race of Abbas became caliphs of the Saracens, and encourage learning.
- 762 The city of Bagdad upon the Tigris, is made the capital for the caliphs of the house of Abbas.
- 800 Charlemagne, king of France, begins the empire of Germany, afterwards called the Western empire; gives the present names to the winds and months; endeavours to restore learning in Europe, but mankind are not yet disposed for it, being solely engrossed in military enterprizes.
- 826 Harold, king of Denmark, dethroned by his subjects, for being a Christian.
- 828 Egbert, king of Wessex, unites the heptarchy, by the name of England.
- 836 The Flemings trade to Scotland for fish.
- 838 The Scots and Picts have a decisive battle, in which the former prevail, and both kingdoms are united by Kenneth, which begins the second period of the Scottish history.
- 867 The Danes begin their ravages in England.
- 896 Alfred the Great, after subduing the Danish invaders, (against whom he fought 56 battles by sea and land), composes his body of laws; divides

Aft. Christ.

Aft. Christ.

- divides England into counties, hundreds, tythings; erects county-courts, and founds the university of Oxford about this time.
- 915 The university of Cambridge founded.
- 936 The Saracen empire is divided by usurpation into seven kingdoms.
- 975 Pope Boniface VII. is deposed and banished for his crimes.
- 979 Coronation oath first used in England. Juries first instituted in ditto.
- 991 The figures in arithmetic are brought into Europe by the Saracens from Arabia; letters of the alphabet were hitherto used.
- 996 Otho III. makes the empire of Germany elective.
- 999 Boleslaus, the first king of Poland.
- 1000 Paper made of cotton rags was in use; that of linen rags in 1170: the manufactory introduced into England at Dartford, 1588.
- 1005 All the old churches are rebuilt about this time in a new manner of architecture.
- 1015 Children forbidden by law to be sold by their parents in England.
- 1017 Canute, king of Denmark, gets possession of England.
- 1040 The Danes, after several engagements with various successs, are about this time driven out of Scotland, and never again return in a hostile manner.
- 1041 The Saxon line restored under Edward the Confessor.
- 1043 The Turks (a nation of adventurers from Tartary, serving hitherto in the armies of contending princes) become formidable, and take possession of Persia.
- 1054 Leo IX. the first pope that kept up an army.
- 1057 Malcolm III. king of Scotland, kills the tyrant Macbeth at Dunlincane, and marries the princess Margaret, sister to Edgar Atheling.
- 1065 The Turks take Jerusalem from the Saracens.
- 1066 The conquest of England by William (surnamed the Bastard) duke of Normandy, in the battle of Hastings, where Harold is slain.
- 1070 William introduces the feudal law. Musical notes invented.
- 1075 Henry IV. emperor of Germany, and the pope, quarrel about the nomination of the German bishops. Henry, in penance, walks barefooted to the pope towards the end of January.
- 1076 Justices of the peace first appointed in England.
- 1080 Doomday-book began to be compiled by order of William, from a survey of all the estates in England, and finished in 1086. The Tower of London built by ditto, to curb his English subjects; numbers of whom fly to Scotland, where they introduce the Saxon or English language, are protected by Malcolm, and have lands given them.
- 1091 The Saracens in Spain, being hard pressed by the Spaniards, call to their assistance Joseph, king of Morocco; by which the Moors get possession of all the Saracen dominions in Spain.
- 1096 The first crusade to the Holy Land is begun under several Christian princes, to drive the infidels from Jerusalem.
- 1110 Edgar Atheling, the last of the Saxon princes, dies in England, where he had been permitted to reside as a subject.
- 1118 The order of the Knights Templars instituted, to defend the Sepulchre at Jerusalem, and to protect Christian strangers.
- 1151 The canon law collected by Gratian, a monk of Bologna.
- 1163 London bridge, consisting of 19 small arches, first built of stone.
- 1164 The Tontonic order of religious knights begins in Germany.
- 1172 Henry II. king of England, (and first of the Plantagenets) takes possession of Ireland; which, from that period, has been governed by an English viceroy, or lord lieutenant.
- 1176 England is divided, by Henry, into six circuits, and justice is dispensed by itinerant judges.
- 1180 Glass windows began to be used in private houses in England.
- 1181 The laws of England are digested about this time by Glanville.
- 1182 Pope Alexander III. compelled the kings of England and France to hold the stirrups of his saddle when he mounted his horse.
- 1186 The great conjunction of the sun and moon and all the planets in Libra, happened in September.
- 1192 The battle of Alcalon, in Judea, in which Richard, king of England, defeats Saladin's army, consisting of 300,000 combatants.
- 1194 *Dieu et mon Droit*, first used as a motto by Richard, on a victory over the French.
- 1200 Chivalries were not known in England. Surnames now began to be used; first among the nobility.
- 1208 London incorporated, and obtained their first charter for electing their Lord Mayor and other magistrates from king John.
- 1215 Magna Charta is signed by king John and the barons of England. Court of common pleas established.
- 1227 The Tartars, a new race of heroes, under Gengis-Kan, emerge from the northern parts of Asia, over-run all the Saracen empire; and, in imitation of former conquerors, carry death and desolation wherever they march.
- 1233 The Inquisition begun in 1204, is now trusted to the Dominicans. The houses of London, and other cities in England, France, and Germany, still thatched with straw.
- 1253 The famous astronomical tables are composed by Alfonso, king of Castile.
- 1258 The Tartars take Bagdad, which finishes the empire of the Saracens.
- 1263 Acho, king of Norway, invades Scotland with 160 sail, and lands 20,000 men at the mouth of the Clyde, who are cut to pieces by Alexander III. who recovers the western isles.
- 1264 The commons of England first summoned to parliament about this time.

- Aft. Christ.
- 1269 The Hamburg company incorporated in England.
- 1273 The empire of the present Austrian family begins in Germany.
- 1282 Lewellyn, prince of Wales, defeated and killed by Edward I. who unites that principality to England.
- 1284 Edward II. born at Carnarvon, is the first prince of Wales.
- 1285 Alexander III. king of Scotland, dies, and that kingdom is disputed by twelve candidates, who submit their claims to the arbitration of Edward, king of England; which lays the foundation of a long and desolating war between both nations.
- 1293 There is a regular succession of English parliaments from this year, being the 22^d of Edward I.
- 1298 The present Turkish empire begins in Bithynia under Ottoman.
Silver-hafted knives, spoons, and cups, a great luxury.
Tallow candles so great a luxury, that splinters of wood were used for lights.
Wine sold by apothecaries as a cordial.
- 1302 The mariner's compass invented, or improved by Givias, of Naples.
- 1307 The beginning of the Swiss cantons.
- 1308 The popes remove to Avignon in France for 70 years.
- 1310 Lincoln's inn society established.
- 1314 The battle of Bannockburn, between Edward II. and Robert Bruce, which establishes the latter on the throne of Scotland.
The cardinals set fire to the conclave and separate.
A vacancy in the papal chair for two years.
- 1320 Gold first coined in Christendom; 1344 ditto in England.
- 1336 Two Brabant weavers settle at York, which, says Edward III. may prove of great benefit to us and our subjects.
- 1337 The first comet whose course is described with an astronomical exactness.
- 1340 Gunpowder and guns first invented by Swartz, a monk of Cologn; 1346 Edward III. had four pieces of cannon, which gained him the battle of Cressy; 1346, bombs and mortars were invented.
Oil painting first made use of by John Vanneck.
Heralds college instituted in England.
- 1344 The first creation to titles by patents used by Edward III.
- 1346 The battle of Durham, in which David, king of Scots, is taken prisoner.
- 1349 The order of the Garter instituted in England by Edward III. altered in 1557, and consists of 26 knights.
- 1352 The Turks first enter Europe.
- 1354 The money in Scotland till now the same as in England.
- 1356 The battle of Poitiers, in which king John of France and his son are taken prisoners by Edward the Black Prince.
- 1357 Coals first brought to London.
- 1358 Arms of England and France first quartered by Aft. Christ. Edward III.
- 1362 The law pleadings in England changed from French to English as a favour of Edward III. to his people.
John Wickliffe an Englishman begins to call in question the doctrines of the church of Rome about this time, whose followers are called Lollards.
- 1386 A company of linen weavers from the Netherlands established in London.
Windfor castle built by Edward III.
- 1388 The battle of Otterburn between Hotspur and the earl of Douglas.
- 1391 Cards invented in France for the king's amusement.
- 1399 Westminster abbey rebuilt and enlarged—Westminster hall ditto.
Order of the Bath instituted at the coronation of Henry IV. renewed in 1725; consisting of 38 knights.
- 1410 Guildhall, London, built.
- 1411 The university of St Andrew's in Scotland founded.
- 1415 The battle of Agincourt gained over the French by Henry V. of England.
- 1428 The siege of Orleans, the first blow to the English power in France.
- 1440 Printing invented by L. Koster at Harlaem in Holland; brought into England by W. Caxton, a mercer of London, 1471.
- 1446 The Vatican library founded at Rome.
The sea breaks in at Dort, in Holland, and drowns 100,000 people.
- 1453 Constantinople taken by the Turks, which ends the eastern empire, 1123 years from its dedication by Constantine the Great, and 2206 years from the foundation of Rome.
- 1454 The university of Glasgow in Scotland founded.
- 1460 Engraving and etching on copper invented.
- 1477 The university of Aberdeen in Scotland founded.
- 1483 Richard III. king of England, and last of the Plantagenets, is defeated and killed at the battle of Bosworth, by Henry (Tudor) VII. which puts an end to the civil wars between the houses of York and Lancaster, after a contest of 30 years, and the loss of 100,000 men.
- 1486 Henry establishes fifty yeomen of the guards, the first standing army.
- 1489 Maps and sea charts first brought to England by Barth. Columbus.
- 1491 William Groceyn introduces the study of the Greek language into England.
The Moors, hitherto a formidable enemy to the native Spaniards, are entirely subdued by Ferdinand, and become subjects to that prince on certain conditions, which are ill observed by the Spaniards, whose clergy use the Inquisition in all its tortures; and in 1609, near one million of the Moors are driven from Spain to the opposite coast of Africa, from whence they originally come.
- 1492 America first discovered by Columbus, a Genoese, in the service of Spain.

- Aft. Christ. 1494 Algebra first known in Europe.
- 1497 The Portuguese first fail to the East Indies by the Cape of Good Hope.
South America discovered by Americus Vesputius, from whom it has its name.
- 1499 North America discovered, for Henry VII. by Cabot, a Venetian.
- 1500 Maximilian divides the empire of Germany into six circles, and adds four more in 1512.
- 1505 Shillings first coined in England.
- 1509 Gardening introduced into England from the Netherlands, from whence vegetables were imported hitherto.
- 1513 The battle of Flowden, in which James IV. king of Scotland is killed, with the flower of his nobility.
- 1517 Martin Luther began the Reformation.
Egypt is conquered by the Turks.
- 1518 Magellan, in the service of Spain, first discovers the straits of that name in South America.
- 1520 Henry VIII. for his writings in favour of popery, receives the title of Defender of the Faith from his Holiness.
- 1529 The name of Protestant takes its rise from the reformed protesting against the church of Rome, at the diet of Spires in Germany.
- 1534 The reformation takes place in England, under Henry VIII.
- 1537 Religious houses dissolved by ditto.
- 1539 The first English edition of the Bible authorized; the present translation finished 1611.
About this time cannon began to be used in ships.
- 1543 Silk stockings first worn by the French king; first worn in England by queen Eliz. 1561; the steel frame for weaving invented by the Rev. Mr Lee, of John's College, Cambridge, 1589.
Pins first used in England, before which time the ladies used skewers.
- 1544 Good lands let in England at one shilling per acre.
- 1545 The famous council of Trent begins, and continues 18 years.
- 1546 First law in England establishing the interest of money at 10 *per cent.*
- 1549 Lords lieutenants of counties instituted in England.
- 1550 Horse guards instituted in England.
- 1555 The Russian company established in England.
- 1558 Queen Elizabeth begins her reign.
- 1560 The reformation in Scotland completed by John Knox.
- 1563 Knives first made in England.
- 1569 Royal Exchange first built.
- 1572 The great massacre of Protestants at Paris.
- 1579 The Dutch shake off the Spanish yoke, and the republic of Holland begins.
English East-India company incorporated—established 1600.
—Turkey company incorporated.
- 1580 Sir Francis Drake returns from his voyage round the world, being the first English circumnavigator.
- Parochial register first appointed in England.
- 1582 Pope Gregory introduces the New Style in Italy; the 5th of October being counted 15.
- 1583 Tobacco first brought from Virginia into England.
- 1587 Mary queen of Scots is beheaded by order of Elizabeth, after 18 years imprisonment.
- 1588 The Spanish Armada destroyed by Drake and other English admirals.
Henry IV passes the edict of Nantes, tolerating the Protestants.
- 1589 Coaches first introduced into England; hackney act 1693; increased to 1000, in 1770.
- 1590 Band of pensioners instituted in England.
- 1591 Trinity college, Dublin, founded.
- 1597 Watches first brought into England from Germany.
- 1602 Decimal arithmetic invented at Bruges.
- 1603 Queen Elizabeth (the last of the Tudors) dies, and nominates James VI. of Scotland (and first of the Stuarts) as her successor; which unites both kingdoms under the name of Great Britain.
- 1605 The Gunpowder-plot discovered at Westminster; being a project of the Roman catholics to blow up the king and both houses of Parliament.
- 1606 Oaths of allegiance first administered in England.
- 1608 Galileo, of Florence, first discovers the satellites about the planet Saturn, by the telescope, then just invented in Holland.
- 1610 Henry IV. is murdered at Paris, by Ravallac, a priest.
- 1611 Barons first created in England by James I.
- 1614 Napier of Merchiston, in Scotland, invents the logarithms.
Sir Hugh Middleton brings the new river to London from Ware.
- 1616 The first permanent settlement in Virginia.
- 1619 W. Harvey, an Englishman, confirms the doctrine of the circulation of the blood, which had been first broached by Servetus, a French physician, in 1553.
- 1620 The broad silk manufacture from raw silk, introduced into England.
- 1621 New England planted by the Puritans.
- 1625 King James dies, and is succeeded by his son, Charles I.
The island of Barbadoes, the first English settlement in the West Indies, is planted.
- 1632 The battle of Lutzen, in which Gustavus Adolphus, king of Sweden, and head of the Protestants in Germany, is killed.
- 1635 Province of Maryland planted by lord Baltimore. Regular posts established from London to Scotland, Ireland, &c.
- 1640 King Charles disoblige his Scottish subjects, on which their army, under general Lesley, enters England, and takes Newcastle, being encouraged by the malecontents in England.
The massacre in Ireland, when 40,000 English Protestants were killed.
- 1642 King Charles impeaches five refractory members, which begins the civil wars in England.
- 1643 Excise on beer, ale, &c. first imposed by parliament.

Afr. Christ.

- 1649 Charles I. beheaded by Cromwell, at Whitehall, January 30, aged 49.
- 1654 Cromwell assumes the protectorship.
- 1655 The English, under admiral Penn, take Jamaica from the Spaniards.
- 1658 Cromwell dies, and is succeeded in the protectorship, by his son Richard.
- 1660 King Charles II. is restored by Monk, commander of the army, after an exile of twelve years, in France and Holland.
The people of Denmark, being oppressed by the nobles, surrender their privileges to Frederick III. who becomes absolute.
- 1662 The Royal Society, established at London, by Charles II.
- 1663 Carolina planted; 1728 divided into two separate governments.
- 1664 The New Netherlands, in North America, conquered from the Swedes and Dutch by the English.
- 1665 The plague rages in London, and carries off 68,000 persons.
- 1666 The great fire of London began Sept. 2, and continued three days, in which were destroyed 13,000 houses, and 400 streets.
Tea first used in England.
- 1667 The peace of Breda, which confirms to the English the New Netherlands, now known by the names of Pennsylvania, New York, and New Jersey.
- 1668 — ditto, Aix la Chapelle.
St James's Park planted, and made a thoroughfare for public use by Charles II.
- 1670 The English Hudson's Bay company incorporated.
- 1672 Lewis XIV. over-runs great part of Holland, when the Dutch opened their sluices, being determined to drown their country, and retire to their settlements in the East Indies.
African company established.
- 1678 The peace of Nimeguen.
The habeas corpus act passed.
- 1680 A great comet appeared, and from its nearness to our earth alarmed the inhabitants. It continued visible from Nov. 3, to March 9.
William Penn, a Quaker, receives a charter for planting Pennsylvania.
- 1683 India stock sold from 360 to 500 per cent.
- 1685 Charles II. dies, aged 55, and is succeeded by his brother James II.
The duke of Monmouth, natural son to Charles II. raises a rebellion, but is defeated at the battle of Sedgmore, and beheaded.
The edict of Nantes is revoked by Lewis XIV, and the Protestants are greatly distressed.
- 1687 The palace of Versailles, near Paris, finished by Lewis XIV.
- 1688 The Revolution in Great Britain begins Nov. 5. King James abdicates, and retires to France, December 3.
King William and queen Mary, daughter and son-in-law to James, are proclaimed February 16.
Viscount Dundee stands out for James in Scotland, but is killed by general Mackey, at the battle

of Killycrankie, upon which the Highlanders, Afr. Christ. wearied with repeated misfortunes, disperse.

- 1689 The land-tax passed in England.
The toleration act passed in ditto.
Several bishops are deprived for not taking the oaths to William.
William Fuller, who pretended to prove the Prince of Wales spurious, was voted by the commons to be a notorious cheat, impostor, and false accuser.
- 1690 The battle of the Boyne, gained by William against James, in Ireland.
- 1691 The war in Ireland finished, by surrender of Limerick to William.
- 1692 The English and Dutch fleets, commanded by Admiral Ruffell, defeat the French fleet off La Hogue.
- 1693 Bayonets at the end of loaded muskets first used by the French against the confederates in the battle of Turin.
The duchy of Hanover made the ninth electorate.
Bank of England established by king William.
The first public lottery was drawn this year.
Massacre of Highlanders at Glencoe, by king William's army.
- 1694 Queen Mary dies at the age of 33, and William reigns alone.
Stamp duties instituted in England.
- 1696 The peace of Ryfwick.
- 1699 The Scots settled a colony at the isthmus of Darien, in America, and called it Caledonia.
- 1700 Charles XII. of Sweden, begins his reign.
King James II. dies at St Germain's, in the 68th year of his age.
- 1701 Prussia erected into a kingdom.
Society for the propagation of the gospel in foreign parts established.
- 1702 King William dies, aged 50, and is succeeded by queen Anne, daughter to James II. who, with the Emperor and States General, renews the war against France and Spain.
- 1704 Gibraltar taken from the Spaniards, by admiral Rooke.
The battle of Blenheim, won by the duke of Marlborough and allies, against the French.
The court of Exchequer instituted in England.
- 1706 The treaty of Union betwixt England and Scotland, signed July 22.
The battle of Ramillies won by Marlborough and the allies.
- 1707 The first British parliament.
- 1708 Minorca taken from the Spaniards by general Stanhope.
The battle of Oudenarde won by Marlborough and the allies.
Sardinia erected into a kingdom, and given to the duke of Savoy.
- 1709 Peter the Great, czar of Muscovy, defeats Charles XII. at Pultowa, who flies to Turkey.
The battle of Malplaquet won by Marlborough and the allies.
- 1710 Queen Anne changes the Whig ministry for others more favourable to the interest of her brother, the late Pretender.

- Aft. Christ. 1710 The cathedral church of St Paul, London, rebuilt by Sir Christopher Wren, in 37 years, at one million expence, by a duty on coals.
The English South-Sea company began.
- 1712 Duke of Hamilton and lord Mohun killed in a duel in Hyde-Park.
- 1713 The peace of Utrecht, whereby Newfoundland, Nova-Scotia, New-Britain, and Hudfon's-Bay, in North America, were yielded to Great Britain; Gibraltar and Minorca, in Europe, were also confirmed to the said crown by this treaty.
- 1714 Queen Anne dies, at the age of 50, and is succeeded by George I.
Interest reduced to five per cent.
- 1715 Lewis XIV. dies, and is succeeded by his great-grandson Lew. is XV. the late king of France.
The rebellion in Scotland begins in September under the earl of Mar, in favour of the Pretender. The action of Sheriff-muir, and the surrender of Preston, both in November, when the rebels disperse.
- 1716 The Pretender married the princess Sobieska, grand-daughter of John Sobieski, late king of Poland.
An act passed for septennial parliaments.
- 1719 The Mississippi scheme at its height in France.
Lombe's silk-throwing machine, containing 26,586 wheels, erected at Derby: takes up one-eighth of a mile; one water-wheel moves the rest; and in 24 hours, it works 318,504,960 yards of organzine silk thread.
The South-Sea scheme in England begun April 7. was at its height at the end of June, and quite sunk about September 29.
- 1727 King George dies, in the 68th year of his age; and is succeeded by his only son, George II.
Inoculation first tried on criminals with success. Russia, formerly a dukedom, is now established as an empire.
- 1732 Kouli Khan usurps the Persian throne, conquers the Mogul empire, and returns with two hundred thirty-one millions Sterling.
Several public-spirited gentlemen begin the settlement of Georgia, in North America.
- 1736 Capt. Porteous having ordered his soldiers to fire upon the populace at an execution of a smuggler, is himself hanged by the mob at Edinburgh.
- 1738 Westminster bridge, consisting of 15 arches, begun; finished in 1750, at the expence of 389,000*l.* defrayed by parliament.
- 1739 Letters of marque issued out in Britain against Spain, July 27, and war declared Oct. 23.
- 1743 The battle of Dettingen won by the English and allies, in favour of the queen of Hungary.
- 1744 War declared against France.—Commodore Anson returns from his voyage round the world.
- 1745 The allies lose the battle at Fontenoy.
The rebellion breaks out in Scotland, and the Pretender's army defeated by the duke of Cumberland, at Culloden, April 16, 1746.
- 1746 British Linen Company erected.
- 1748 The peace of Aix-la-Chapelle, by which a restitution of all places taken during the war, was to be made on all sides.
- 1749 The interest on the British funds reduced to 3 per cent.
British herring-fishery incorporated.
- 1751 Frederic, prince of Wales, father to his present majesty, died.
Antiquarian society at London incorporated.
- 1752 The new stile introduced into Great Britain; the 3^d of September being counted the 14th.
- 1753 The British museum erected at Montague-house.
Society of arts, manufactures, and commerce, instituted in London.
- 1755 Lisbon destroyed by an earthquake.
- 1756 146 Englishmen are confined in the black hole at Calcutta, in the East Indies, by order of the nabob, and 123 found dead next morning.
Marine society established at London.
- 1757 Damien attempted to assassinate the French king.
- 1759 General Wolf is killed in the battle of Quebec, which is gained by the English.
- 1760 King George II. dies October 25, in the 77th year of his age, and is succeeded by his present majesty, who, on the 22^d of September, 1761, married the princess Charlotte, of Mecklenburgh Strelitz.
Black-friars bridge, consisting of 9 arches, begun; finished 1770, at the expence of 152,840*l.* to be discharged by a toll.
- 1762 War declared against Spain.
Peter III. emperor of Russia, is deposed, imprisoned, and murdered.
American philosophical society established in Philadelphia.
George Augustus Frederic, prince of Wales, born Aug. 12.
- 1763 The definitive treaty of peace between Great-Britain, France, Spain, and Portugal, concluded at Paris, February 10, which confirms to Great-Britain the extensive provinces of Canada, East and West Florida, and part of Louisiana, in North America; also the islands of Granada, St Vincent, Dominica, and Tobago, in the West Indies.
- 1764 The parliament granted 10,000*l.* to Mr Harrison, for his discovery of the longitude by his time-piece.
- 1765 His majesty's royal charter passed for incorporating the society of artists.
An act passed annexing the sovereignty of the island of Man to the crown of Great Britain.
- 1766 April 21, a spot or macula of the sun, more than thrice the bigness of our earth, passed the sun's center.
- 1768 Academy of painting established in London.
The Turks imprison the Russian ambassador, and declare war against that empire.
- 1771 Dr Solander and Mr Banks, in his majesty's ship the Endeavour, lieut. Cooke, return from a voyage round the world, having made several important discoveries in the South-Seas.
- 1772 The king of Sweden changes the constitution from aristocracy to a limited monarchy.
The pretender marries a princess of Germany, grand-daughter of Thomas, late Earl of Aylbury.
- The emperor of Germany, empress of Russia,

and the king of Prussia, strip the king of Poland of a great part of his dominions, which they divide among themselves, in violation of the most solemn treaties.

- 1773 Captain Phipps is sent to explore the North Pole, but having made 81 degrees, is in danger of being locked up by the ice, and his attempt to discover a passage in that quarter proves fruitless.

The Jesuits expelled from the Pope's dominions. The English East India company having, by conquest or treaty, acquired the extensive provinces of Bengal, Orixa, and Bahar, containing 15 millions of inhabitants, great irregularities are committed by their servants abroad; upon which government interferes, and sends out judges, &c. for the better administration of justice.

- 1773 The war between the Russians and the Turks Aft. Christ. proves disgraceful to the latter, who lose the islands in the Archipelago, and by sea are every where unsuccessful.
- 1774 Peace is proclaimed between the Russians and Turks.
- The British parliament having passed an act, laying a duty of 3 d. per pound upon all teas imported into America; the colonists, considering this as a grievance, deny the right of the British parliament to tax them.
- 1775 The American colonies send deputies to Philadelphia, who assume the title of *The Congress of the Thirteen United Provinces*, and all the powers of government.
- 1776 The congress declare the *United States of America* independent of the crown and parliament of Great Britain.

C H R

CHRONOMETER, in general, denotes any instrument or machine used in measuring time; such are dials, clocks, watches, &c. See DIAL, &c.

The term *chronometer*, however, is generally used in a more limited sense, for a kind of clock so contrived as to measure a small portion of time with great exactness, even to the sixteenth part of a second: of such a one there is a description in Desaguliers's experimental philosophy, invented by the late ingenious Mr George Graham; which must be allowed to be of great use for measuring small portions of time in astronomical observations, the time of the fall of bodies, the velocity of running waters, &c. But long spaces of time cannot be measured by it with sufficient exactness, unless its pendulum be made to vibrate in a cycloid; because, otherwise it is liable to err considerably, as all clocks are which have short pendulums that swing in large arches of a circle.

There have been several machines contrived for measuring time, under the name of *chronometers*, upon principles very different from those on which clocks and watches are constructed.

Plate LXXXII. fig. 4. represents an *air-chronometer*, which is constructed in the following manner. Provide a glass tube of about an inch in diameter, and three or four feet long: the diameter of the inside of this tube must be precisely equal in every part: at the bottom must be a small hole, closely covered with a valve. In the tube place a piston E, fig. 5. which is made to fit it exactly, and must be oiled, that it may move in the tube with the greatest freedom: in this piston there is a cock that shuts quite close; and from the top of it there goes a cord F, which passes through the handle G. The cock of the piston being closed, it is to be let down to the bottom of the tube; and being then drawn up to the top, the air will then rush in by the valve at the bottom of the tube, and support the piston. You are then to turn the cock, so as to make a very small vent; and the air passing slowly through that vent, the piston will gradually descend, and shew the hour, either by lines cut in the tube with a diamond, or marked with paint, or by small slips of paper painted on the glass. If this chronometer should go too fast or too slow, it may be easily regulated by

C H R

altering the position of the cock in the piston, as it is on that the whole depends.

If, instead of marking the tube, you would have the time shown by a dial, it may be easily effected by placing an axis to which the hand of the dial is fixed, directly over the tube, and winding the string to which the piston is joined, round that axis; for then, as the piston descends, the axis will gradually turn the hand, and show the hour: but it must be observed, that as the descent of the piston is not constantly regular, on account of the decrease of resistance from the quantity of the subjacent air as the piston descends, the axis therefore must not be a regular cylinder, but conical like the fusee of a watch, as in fig. 6. by which means the motion of the hand of the dial will be constant and regular.

Fig. 7. represents a lamp-chronometer. It consists of a chamber lamp A, which is a cylindrical vessel about three inches high, and one inch diameter, placed in the stand B. The inside of this vessel must be every where exactly of the same diameter. To the stand B is fixed the handle C, which supports the frame DEFG, about 12 inches high, and four wide. This frame is to be covered with oiled paper, and divided into twelve equal parts by horizontal lines; at the end of which are wrote the numbers for the hours, from 1 to 12, and between the horizontal lines are diagonals that are divided into halves, quarters, &c. On the handle B, and close to the glass, is fixed the style or gnomon H. Now, as the distance of the style from the flame of the lamp is only half an inch, if the distance of the frame from the style is only six inches, then, while the float that contains the light descends, by the decrease of the oil, one inch, the shadow of the style on the frame will ascend twelve inches, that is, its whole length, and show by its progression the regular increase of the hours, with their several divisions. It is absolutely necessary, however, that the oil used in this lamp be always of the same sort and quite pure, and that the wick also be constantly of the same size and substance, as it is on these circumstances, and the uniform figure of the vessel, that the regular progress of the shadow depends.

CHRONOMETER, among musicians, an instrument invented

Chronometer—invented by *Loudie*, a French musician, for the purpose of measuring time by means of a pendulum. The form of the instrument as described by him, is that of an Ionic pilaster, and is thus described by Malcolm in his treatise of Music, p. 407.—“The chronometer consists of a large ruler or board, six feet or 72 inches long, to be set on end; it is divided into its inches, and the numbers set so as to count upwards; and at every division there is a small round hole, through whose center the line of division runs. At the top of this ruler, about an inch above the division 72, and perpendicular to the ruler, is inserted a small piece of wood, in the upper side of which there is a groove, hollowed along from the end that stands out to that which is fixed in the ruler, and near each end of it a hole is made: through these holes a pendulum cord is drawn, which runs in the groove; at that end of the cord which comes through the hole furthest from the ruler, the ball is hung; and at the other end there is a small wooden pin, which can be put in any of the holes of the ruler: when the pin is in the uppermost hole at 72, then the pendulum from the top to the centre of the ball must be exactly 72 inches; and therefore, whatever hole of the ruler it is put in, the pendulum will be just so many inches as that figure at the hole denotes. The manner of using the machine is this: The composer lengthens or shortens his pendulum, till one vibration be equal to the designed length of his bar, and then the pin stands at a certain division, which marks the length of the pendulum; and this number being set with the clasp at the beginning of the song, is a direction for others how to use the chronometer in measuring the time according to the composer's design: for with the number is set the note, crotchet, or minim, whose value he would have the vibration to be; which in brisk duple time is best a minim or half bar, or even a whole bar, when that is but a minim; and in slow time, a crotchet. In triple time, it would do well to be the third part or half, or fourth part of a bar; and in the simple triples that are allegro, let it be a whole bar. And if, in every time that is allegro, the vibration is applied to a whole or half bar, practice will teach us to subdivide it justly and equally. Observe, that, to make this machine of universal use, some canonical measure of the divisions must be agreed upon, that the figure may give a certain direction for the length of the pendulum.

CHROSTASIMA, in natural history, a genus of pellucid gems, comprehending all those which appear of one simple and permanent colour in all lights; such are the diamond, carbuncle, ruby, garnet, amethyst, sapphire, beryl, emerald, and the topaz. See **DIAMOND**, **CARBUNCLE**, &c.

CHRYALIS, or **AURELIA**, in natural history, a state of rest and seeming insensibility, which butterflies, moths, and several other kinds of insects, must pass through before they arrive at their winged or most perfect state.

In this state, no creatures afford so beautiful a variety as the butterfly kinds, and they all pass through this middle state without one exception. The figure of the aurelia or chrysalis generally approaches to that of a cone, or at least the hinder part of it is in this

shape; and the creature, while in this state, seems to have neither legs nor wings, nor has any power of walking. It seems indeed to have hardly so much as life. It takes no nourishment in this state, nor has it any organs for taking any; and indeed its posterior part is all that seems animated, this having a power of giving itself some motions. The external covering of the chrysalis is cartilaginous, and considerably large, and is usually smooth and glossy; but some few of them have a few hairs; some are also as hairy as the caterpillars from which they are produced; and others are rough, and, as it were, flangeered all over.

In all of these there may be distinguished two sides; the one of which is the back, the other the belly of the animal. On the anterior part of the latter, there may always be distinguished certain little elevations running in ridges, and resembling the fillets found about mummies: the part whence these have their origin, is esteemed the head of the animal. The other side, or back, is smooth, and of a rounded figure in most of the chrysalises; but some have ridges on the anterior part, and sides of this part; and these usually terminate in a point, and make an angular appearance on the chrysalis.

From this difference is drawn the first general distinction of these bodies. They are by this divided into two classes; the round and the angular kinds. The first are, by the French naturalists, called *ferres*; from the common custom of calling the chrysalis of the silkworm, which is round, by this name.

There is something more regular in this distinction than might at first be conceived; for the division is continued from the fly-state: the rounded chrysalises being almost all produced by the *phalena* or moths; and the angular ones by the *papilio*, or day-flies. There are several subordinate distinctions of these kinds; but, in general, they are less different from one another than the caterpillars from whence they are produced.

The head of those of the first class usually terminates itself by two angular parts, which stand separate one from the other, and resemble a pair of horns. On the back, eminences and marks are discovered, which imagination may form into eyes, nose, chin, and other parts of the human face.

There is a great variety and a great deal of beauty in the figures and arrangement of the eminences and spots on the other part of the body of the chrysalises of different kinds. It is a general observation, that those chrysalises which are terminated by a single horn, afford day-butterflies of the kind of those which have buttoned antennæ, and whose wings, in a state of rest, cover the under part of their body, and which use all their six legs in walking, those of many other kinds using only four of them. Those chrysalises which are terminated by two angular bodies, and which are covered with a great number of spines, and have the figure of a human face on their back in the greatest perfection, afford butterflies of the day-kind; and of that class the characters of which are, their walking on four legs, and using the other two, that is, the anterior part, in the manner of arms or hands. The chrysalises which have two angular bodies on their heads, but shorter than those of the preceding, and whose

Chrysalis.

Chrysalis.

whose back shews but a faint sketch of the human face, and which have fewer spines, and those less sharp, always turn to that sort of butterfly the upper wings of which are divided into segments, one of which is so long as to represent a tail, and whose under wings are folded over the upper part of the back. A careful observation will establish many more rules of this kind, which are not so perfect as to be free from all exceptions; yet are of great use, as they teach us in general what sort of fly we are to expect from the chrysalis, of which we know not the caterpillar, and therefore can only judge from appearances.

These are the principal differences of the angular chrysalises; the round ones also have their different marks not less regular than those.

The greater number of the round chrysalises have the hinder part of their body of the figure of a cone; but the upper end, which ought to be its circular plane base, is usually bent and rounded into a sort of knee: this is usually called the head of the chrysalis; but there are also some of this kind, the head of which is terminated by a nearly plane surface: some of the creeping ten-legged caterpillars give chrysalises of this kind, which have each of them two eminences that seem to bring them towards the angular kind.

Among the angular chrysalises there are some whose colours seem as worthy our observation as the shapes of the others. Many of them appear superbly clothed in gold. These elegant species have obtained the name of *chrysalis* and *aurelia*, which are derived from Greek and Latin words, signifying gold; and from these all other bodies of the same kind have been called by the same names, though less, or not at all, entitled to them. As some kinds are thus gilded all over, so others are ornamented with this gay appearance in a more sparing manner, having only a few spots of it in different places on their back and belly. These obvious marks, however, are not to be depended upon as certain characters of distinction: for accidents in the formation of the chrysalis may alter them; and those which naturally would have been gilded all over, may be sometimes only so in part; and either these or the others may, by accident, be so formed, as to shew nothing of this kind at all, but be only of a dusky brown. Those, however, which have neither silver nor gold to recommend them to your eyes, do not want other colours, and those beautifully variegated. Some of them are all over of an elegant green, as is the chrysalis of the fennel-caterpillar; others of an elegant yellow; and some of a bright-greenish tinge, variegated with spots of a shining black: we have a very beautiful instance of this last kind in the chrysalis of the elegant cabbage-caterpillar. The general colour of the chrysalis of the common butterflies, however, is brown.

Some are also of a fine deep black; and of these many are so smooth and glossy, that they are equal to the finest Indian jasper. The common caterpillar of the fig-tree gives an instance of one of these most beautiful glossy ones; the caterpillar of the vine affords another of these fine black chrysalises.

The rounded chrysalises do not afford any thing of that variety of colouring so remarkably beautiful in the angular ones; they are usually of a dusky yellow,

in different shades, and are often variously spotted with black: but these, as well as all other chrysalises, before they arrive at their fixed colour, pass through several other temporary ones; some being of a different colour when first produced from the caterpillar, from what they are a few days afterwards; and some varying so greatly, though only in degree, as not to be distinguishable, even by the most conversant eye, from what they were when first produced. The green rough caterpillar of the cabbage has a chrysalis which is green at first; and from that gradually goes through all the shades of green to a faint yellow, which is its lasting colour; and one of the oak caterpillars yields a chrysalis beautifully spotted with red at its first appearance; but these spots change to brown for their fixed colour: the third day from their formation usually fixes their lasting colours; and if they are observed to turn black in any part after this time, it is a sign that they are dead or dying.

The several species of insects, as a fly, spider, and an ant, do not differ more evidently from one another in regard to appearance, than do a caterpillar, its chrysalis, and a butterfly produced from it; yet it is certain, that these are all the product of the same individual egg; and nothing is more certain, than that the creature which was for a while a caterpillar, is, after a certain time, a chrysalis, and then a butterfly. These great changes produced in so sudden a manner, seem like the *metamorphoses* recorded in the fables of the ancients; and indeed it is not improbable that those fables first took their origin from such changes.

The parts being distinguishable in the chrysalis, we easily find the difference of the species of the fly that is to proceed from it. The naked eye shews whether it be one of those that have, or of those that have not, a trunk; and the assistance of a microscope shews the antennæ so distinctly, that we are able to discern whether it belongs to the day or night-class; and often to what genus, if not the very species: nay, in the plumose horned kinds, we may see, by the antennæ, whether a male or female phalena is to be produced from the chrysalis; the horns of the female being in this state evidently narrower, and appearing less elevated above the common surface of the body, than those of the male.

All these parts of the chrysalis, however, though seen very distinctly, are laid close to one another, and seem to form only one mass; each of them is covered with its own peculiar membrane in this state, and all are surrounded together by a common one; and it is only through these that we see them; or rather we see on these the figures of all the parts moulded within, and therefore it requires attention to distinguish them. The chrysalis is soft when first produced, and is wetted on the front with a viscous liquor; its skin, though very tender at first, dries and hardens by degrees: but this viscous liquor which surrounds the wings, legs, &c. hardens almost immediately; and in consequence fastens all those limbs, &c. into a mass, which were before loose from one another: this liquor, as it hardens, loses its transparency, and becomes brown; so that it is only while it is yet moist that these parts are to be seen distinct.

Chrysalis.

Chrysalis.

It is evident from the whole, that the chrysalis is no other than a butterfly, the parts of which are hid under certain inembranes which fasten them together ; and, when the limbs are arrived at their due strength, they become able to break through these membranes, and then expand and arrange themselves in their proper order.

The first metamorphosis, therefore, differs nothing from the second, except that the butterfly comes from the body of the caterpillar in a weak state, with limbs unable to perform their offices, whereas it comes from the chrysalis perfect.

Hist. of Insects, vol. i. p. 2—28.

M. Reaumur has given us many curious observations on the structure and uses of the several coverings that attend the varieties of the caterpillar-kind in this state.

The creatures in general remain wholly immovable in this state, and seem to have no business in it but a patient attendance on the time when they are to become butterflies ; and this is a change that can happen to them, only as their parts, before extremely soft and weak, are capable of hardening and becoming firm by degrees, by the transpiration of that abundant humidity which before kept them soft : and this is proved by an experiment of M. Reaumur, who, inclosing some chrysalides in a glass tube, found, after some time, a small quantity of water at the bottom of it ; which could have come there no other way, but from the body of the inclosed animal. This transpiration depends greatly on the temperature of the air ; it is increased by heat, and diminished by cold ; but it has also its peculiarities in regard to the several species of butterfly to which the chrysalis belongs.

According to these observations, the time of the duration of the animal in the chrysalis state must be, in different species, very different ; and there is indeed this wide difference in the extremes, that some species remain only eight days in this state, and others eight months.

We know that the caterpillar changes its skin four or five times during its living in that state ; and that all these skins are at first produced with it from the egg, lying closely over one another. It parts with, or throws off all these one by one, as the butterfly, which is the real animal, all this time within, grows more and more perfect in the several first changes. When it throws off one, it appears in another skin exactly of the same form ; but at its final change from this appearance, that is, when it throws off the last skin, as the creature within is now arrived at such a degree of perfection as to need no farther taking of nourishment, there is no farther need of teeth, or any of the other parts of a caterpillar. The creature, in this last change, proceeds in the very same manner as in all the former, the skin opening at the back, and the animal making its way out in this shape. If a caterpillar, when about to throw off this last skin, be thrown into spirits of wine, and left there for a few days, the membranes within will harden, and the creature may be afterwards carefully opened, and the chrysalis taken out, in which the form of the tender butterfly may be traced in all its lineaments, and its eyes, legs, &c. evidently seen. It is not necessary, however, to seize upon this exact time for proving

the existence of the chrysalis or butterfly in the caterpillar : for if one of these animals be thrown into spirit of wine, or into vinegar, some days before that time, and left there for the flesh to harden, it may afterwards be dissected, and all the lineaments of the butterfly traced out in it ; the wings, legs, antennæ, &c. being as evident here, and as large, as in the chrysalis.

It is very plain from this, that the change of the caterpillar into chrysalis is not the work of a moment ; but is carrying on for a long time before, even from the very hatching of the creature from the egg. The parts of the butterfly, however, are not disposed exactly in the same manner while in the body of the caterpillar, as when left naked in the form of the chrysalis : for the wings are proportionally longer and narrower, being wound up into the form of a cord ; and the antennæ are rolled up on the head ; the trunk is also twisted up and laid upon the head ; but this in a very different manner from what it is in the perfect animal, and very different from that in which it lies within the chrysalis ; so that the first formation of the butterfly in the caterpillar, by time arrives at a proper change of the disposition of its parts, in order to its being a chrysalis. The very eggs, hereafter to be deposited by the butterfly, are also to be found not only in the chrysalis, but in the caterpillar itself, arranged in their natural, regular order. They are indeed in this state very small and transparent ; but after the change into the chrysalis, they have their proper colour.

As soon as the several parts of the butterfly, therefore, are arrived at a state proper for being exposed to the more open air, they are thrown out from the body of the caterpillar surrounded only with their membranes ; and as soon as they are arrived after this at a proper degree of strength and solidity, they labour to break through these thinner coverings, and to appear in their proper and natural form. The time of their duration in this state of chrysalis is very uncertain, some remaining in it only a few days, others several months, and some almost a year in appearance. But there is a fallacy in this that many are not aware of. It is natural to think, that as soon as the creature has inclosed itself in its shell, be that of what matter it will, it undergoes its change into the chrysalis state. And this is the case with the generality : yet there are some which are eight or nine months in the shell before they become chrysalides ; so that their duration in the real chrysalis state is much shorter than it naturally appears to be. M. Reaumur carefully watched the auriculated caterpillar of the oak into its several changes, and particularly from its chrysalis, which is of this last kind, into the fly ; and has given an account of the method of this as an instance of the general course of nature in these operations.

The membranes which envelope the creature in this chrysalis state are at first tough and firm, and immediately touch the several parts of the inclosed animal ; but by degrees, as these parts harden, they become covered, some with hairs, and others with scales. These, as they continue to grow, by degrees fall off the several particular membranes which cover the parts.

Chrysalis.

Chrysalis, parts on which they are placed, to a greater distance, and by degrees loosen them from the limbs. This is one reason of those membranes drying and becoming brittle.

The middle of the upper part of the *CORCELET* is usually marked with a line which runs in a longitudinal direction; and this part is always more elevated than the rest, even in the conic kinds, which are no otherwise angular. This line is in some very bold and plain; in others, it is so faint as not to be distinguishable without glasses; but it is always in the midst of that line that the shell begins to open. The motion of the head of the butterfly backwards first occasions this crack; and a few repetitions of the same motions open it the whole length of the line.

The clearing itself, however, entirely, is a work of more time in this case, than is the passing of the chrysalis out of the body of the caterpillar. In that case there is a crack sufficiently large in the skin of the back, and the whole chrysalis being loose comes out at once. But in this case, every particular limb, and part of the body, has its separate case; and these are almost inconceivably thin and tender, yet it is necessary that every part be drawn out of them before it appear naked to the open air. As soon as all this is effected, and the animal is at full liberty, it either continues some time upon the remains of its covering, or creeps a little way distant from it, and there rests. The wings are what we principally admire in this creature. These are at this time so extremely folded up, and placed in so narrow a compass, that the creature seems to have none at all; but they by degrees expand and unfold themselves; and finally, in a quarter of an hour, or half an hour at the utmost, they appear at their full size, and in all their beauty. The manner of this sudden unfolding of the wings is this: the small figure they make when the creature first comes out of its membranes, does not prevent the observing that they are at that time considerably thick. This is owing to its being a large wing folded up in the nicest manner, and with folds so arranged as to be by no means sensible to the eye, for the wing is never seen to unfold; but, when observed in the most accurate manner, seems to grow under the eye to this extent. When the creature is first produced from the shell, it is every where moist and tender; even its wings have no strength or stiffness till they expand themselves; but they then dry by degrees, and, with the other parts, become rigid and firm. But if any accident prevents the wings from expanding at their proper time, that is, as soon as the creature is out of its shell, they never afterwards are able to extend themselves; but the creature continues to wear them in their contracted and wholly useless state; and very often, when the wings are in part extended before such an accident happens, it stops them in a partial extension, and the creature must be contented to pass its whole life with them in that manner.

M. Reaumur has proved, that heat and cold make great differences in the time of hatching the butterfly from its chrysalis state: and this he particularly tried with great accuracy and attention, by putting them in vessels in warm rooms, and in ice-houses; and it seemed wholly owing to the hastening or retarding the eva-

poration of the abundant humidity of the animal in the chrysalis state, that it sooner or later appeared in the butterfly form. He varnished over some chrysalises, in order to try what would be the effect of thus wholly preventing their transpiration; and the consequence was, that the butterfly came forth from these two months later than their natural time. Thus was the duration of the animal in this state lengthened; that is, its existence was lengthened; but without any advantage to the creature, since it was in the time of its state of inaction, and probably of insensibility.

Though this was of no consequence, Mr Reaumur deduces a hint from it that seems to be of some use. He observes that hen's eggs, of which we make so many uses, and eat in so many forms, are properly a sort of chrysalis of the animal; their germ, after they are impregnated by the cock, containing the young animal alive, and waiting only a due degree of warmth to be hatched, and appear in its proper form. Eggs transpire notwithstanding the hardness of their shells; and when they have been long kept, there is a road found near one of their ends, between the shell and the internal membrane; this is a mark of their being stale, and is the effect of an evaporation of part of their humidity: and the same varnish which had been used to the chrysalis, being tried on eggs, was found to preserve them for two years, as fresh as if laid but the same day, and such as the nicest palate could not distinguish from those that were so. See EGGS.

It is not yet known how much further this useful speculation might be carried, and whether it might not be of great use even to human life, to invent something that should act in the manner of this varnish, by being rubbed over the body, as the *athleta* did of old, and the savages of the West Indies do at this time, without knowing why. But to return to the insects which are the subjects of this article; their third state, that in which they are winged, is always very short, and seems destined for no other action but the propagation of the species. See PAPILIO.

CHRYSANTHEMUM, CORN-MARIGOLD; a genus of the polygamia superflua order, belonging to the syngenesia class of plants. There are 19 species, of which the following are the most remarkable: 1. The ferotinum is a native of North America. The roots of this plant creep far under the surface, and send up strong stalks more than four feet high, garnished with long sawed leaves ending in points. These stalks divide upward into many smaller; each being terminated by a large, white, radiated flower, which appears in the end of August or September. 2. The coronarium hath been long cultivated in the gardens on account of the beauty of its flowers. It grows to the height of three feet, with a single upright stalk divided into numerous branches, garnished with pinated leaves, and crowned with elegant compound flowers of different colours and properties. The varieties are, single and double flowers of a cream colour; yellow; yellow and white; brimstone-coloured; fiftular, or quilled; or those with finely jagged leaves, and flowers of all the above colours and properties. All the varieties begin flowering in July: the flowers are exceedingly numerous, and exhibit a constant succession of full bloom till November; and both single and

Chrysalis
|
Chrysanthemum.

Chrysanthemum
Chryso-
balanus.

and double are succeeded by abundance of seed. 3. The puticifens is a native of the Canary Islands. It rises with a shrubby stalk near two feet high, dividing into many branches, which are garnished with pretty thick succulent leaves, of a greyish colour, cut into many segments. The flowers come out from the wings of the leaves, growing upon naked foot-stalks singly, which greatly resemble those of chamomile. There is a succession of flowers on the same plant for the greatest part of the year, for which it is chiefly esteemed. This plant will perfect seeds in Britain when the seasons are favourable.

Culture. The first kind multiplies very fast by its creeping roots, and will thrive in any soil or situation. The second may be raised in abundance from seed, either in a hot-bed or warm border, in the spring, for transplanting; also by cuttings and slips of their branches in autumn. The latter method is practised only for the propagation of the fine doubles, for an early bloom the following summer; and the best time to perform it is in September, or early in October. Cut off, at that time, a quantity of the robust side shoots, from three to six inches long, without flowers; divest them of the lower leaves, and plant many of them together in large pots, within an inch or two of their tops, and two or three inches apart; give some water, and place them in the shade during the hot weather: by the end of October they will be rooted, when the pots are to be removed either into a green-house or garden-frame, for the winter; but the latter is the most eligible, where they may enjoy the full air in mild weather, and have occasional shelter from frost. In April they may be transplanted singly into borders, and some in pots. The plants thus raised will flower a month or six weeks sooner the succeeding summer than those raised in the spring from seed; but as they soon become barren, it is proper to have always a quantity of plants raised from the seed. The third sort may be raised either from seeds or cuttings, but requires to be sheltered in the green-house in winter.

CHRYSIPPUS, a Stoic philosopher, born at Solos in Cilicia, was disciple to Cleanthes, Zeno's successor. He wrote many books, several of which related to logic. None of the philosophers spoke in stronger terms of the fatal necessity of every thing, nor more pompously of the liberty of man, than the Stoics, Chrysippus in particular. He was so considerable among them, as to establish it into a proverb, that if it had not been for Chrysippus, the porch had never been. Yet the Stoics complained, as Cicero relates, that he had collected so many arguments in favour of the sceptical hypothesis, that he could not answer them himself; and thus had furnished Carneades, their antagonist, with weapons against them. There is an apophthegm of this philosopher preserved, which does him honour. Being told that some persons spoke ill of him, "It is no matter," (said he), "I will live so that they shall not be believed."

CHRYSOBALANUS, COCOA PLUM; a genus of the monogynia order, belonging to the icofandria class of plants. There is only one species, the icaco, which is a native of the Bahama islands, and many other parts of America, but commonly grows near the sea. It rises with a shrubby stalk eight or nine feet high,

sending out several side-branches, which are covered with a dark brown bark. The flowers are white, and are succeeded by plums like damsons; some blue, some red, and others yellow. The stone is shaped like a pear, and has five longitudinal ridges. They are propagated by seeds, which must be procured from the places where they grow naturally. The management is the same as in other tender plants which are natives of those climates.

CHRYSOCOLLA, the Greek name for BORAX.

CHRYSOCOMA, GOLDY-LOCKS; a genus of the polygamia æqualis order, belonging to the lyngensia class of plants. There are nine species, the most remarkable of which are, the linofyris, the coma aurea, and the cornua. These are herbaceous flowering perennials growing from one to two feet high, ornamented with narrow leaves, and compound floscular flowers of a yellow colour. They are easily propagated by dividing the roots or cuttings; but the two last require to be sheltered in the green-house in winter.

CHRYSOLARAS (Emanuel), one of those learned men in the 14th century, who brought the Greek literature into the west. He was a man of rank; and descended from an ancient family, said to have removed with Constantine from Rome to Byzantium. He was sent into Europe by the emperor of the east to implore the assistance of the Christian princes. He afterwards taught at Florence, Venice, Pavia, and Rome; and died at Constantinople, in 1415, aged 47. He wrote a Greek grammar, and some other small pieces.

CHRYSLITE, the name given by the moderns to a gem, which was called the topaz by the ancients. All the modern jewellers, and those of several ages before them, have agreed in calling this gem the chrysolite: and the true chrysolite of the ancients, which had its name from its fine gold yellow colour, they now universally call the topaz.

The chrysolite of our times, the topaz of the ancients, is, even in its most pure and perfect state, a gem of but small beauty, and little value. It is found of various sizes, and some of the coarser pieces of it are vastly larger than those of any of the other gems are ever found to be: its most frequent size, however, when perfect, is about the size of a nutmeg. It is found of very various figures, but never columnar, or in the form of crystal: it is in some places found small, or in irregular pebble-like masses; in others, generally oblong and flattened; and is always of a rude surface, and less bright than any of the other gems. Its colour is a dead green, with a faint admixture of a pale yellow. It has these different tinges, in the several specimens, in different degrees of mixture; but its most usual colour is that of an unripe olive with somewhat of a brassy colour mixed with it; and sometimes it is of a pale and dusky green, obscured by a mixture of brown, and with a slight cast of the same brassy yellow. It is much softer than any of the pellucid gems; its finest pieces do not exceed crystal in hardness, and its coarser are greatly softer: it takes a good polish, however; and, in some of its finer specimens, makes a tolerable appearance, though greatly inferior to the other gems. Our jewellers take very

Chryso-
colla
Chrysolite.

Chrysolite
Chrysothorn

little notice of it; and instead of having two or three names for it, as they have for most of the other gems, they call it very often a *prafius*, and the less accurate among them often call the chryloprafius a *chryfolite*. This ftone is found in New Spain, and alfo in feveral parts of Europe, as in Silefia, Bohemia, &c. The American chryfolites, however, are greatly fuperior to the European; but they are ufually fmall: the Bohemian are large, but very few of them are of a good colour, or free from flaws.

CHRYsolITE-Pafte, a kind of glafs made in imitation of natural chryfolite, by mixing two ounces of prepared cryftal with ten ounces of red-lead, adding twelve grains of crocus martis made with vinegar; and then baking the whole for twenty-four hours, or longer, in a well luted cucurbit.

CHRYsOMELA, in zoology, a genus of infefts, belonging to the order of coleoptera. The antennæ are fhaped like bracelets, and thicker on the outfide; and neither the breaft nor the elytra are margined. There are no lefs than 122 fpecies enumerated by Linnaeus, principally diftinguifhed by differences in their colour.

CHRYsOPHYLLUM, or **BULLY-TREE**, a genus of the monogynia order, belonging to the pentandria clafs of plants. There are two fpecies, the camito and glabrum, both natives of the Weft Indies. The firft rifes 30 or 40 feet high, with a large trunk covered with a brown bark, and divides into many flexible flender branches, which generally hang downward, garnifhed with fpear-fhaped leaves, whole under fides are of a bright ruftlet colour. The flowers come out at the extremities of the branches, difpofed in oblong bunches, which are fucceeded by fruit of the fize of a golden pippin, that are very rough to the palate, and aftringent; but when kept fome time mellow, as is praftifed here with medlars, they have an agreeable flavour. The fecond fort never rifes to the height of the firft, nor do the trunks grow to half the fize; but the branches are flender and garnifhed with leaves like thofe of the firft. The flowers come out in clufters from the fide of the branches, which are fucceeded by oval fmoth fruit about the fize of olives, inclofing three or four hard compreffed feeds. Both thefe plants are frequently preferred in gardens where there are large ftoves, and are propagated by feeds, but the plants can never bear the open air in this country.

CHRYsOPRASUS, or **CHRYsOPRASius**, the tenth of the precious ftones, mentioned in the Revelations, as forming the foundation of the heavenly Jerufalem. The chryloprafius is a fpecies of prafius, of a pale, but pure green colour, with an admixture of yellow.

CHRYsOSTOM (St John), a celebrated patriarch of Conftantinople, and one of the moft admired fathers of the Chriftian church, was born of a noble family at Antioch, about the year 347. He ftudied rhetoric under Libavius, and philofophy under Andragathus: after which he fpent fome time in folitude in the mountains near Antioch; but the aufterities he endured, having impaired his health, he returned to Antioch, where he was ordained deacon by Meletius Flavian, Meletius's fucceffor, raifed him to the office

of prefbyter five years after; when he diftinguifhed himfelf fo greatly by his eloquence, that he obtained the furname of *Golden Mouth*. Neftarius patriarch of Conftantinople, dying in 397, St Chryfoftom, whole fame was fpread throughout the whole empire, was chofen in his room by the unanimous confent of both the clergy and the people. The emperor Arcadius confirmed this election, and caufed him to leave Antioch privately, where the people were very unwilling to part with him. He was ordained bifhop on the 26th of February, 398; when he obtained an order from the emperor againft the Eunomians and Montanifts; reformed the abufes which fubfifted againft his clergy; retrenched a great part of the expences in which his predeceffors had lived, in order to enable him to feed the poor and build hofpitals; and preached with the utmoft zeal againft the pride, luxury, and avarice of the great. But his pious liberty of fpeech procured him many powerful enemies. He differed with Theophilus of Alexandria, who got him depofed and banifhed; but he was foon recalled. After this, declaiming againft the dedication of a ftatue erected to the emperrefs, fhe banifhed him into Cucufus in Armenia, a moft barren, inhofpitable place; afterwards, as they were removing him from Petyus, the foldiers treated him fo roughly, that he died by the way, *A. D.* 407. The beft edition of his works is that published at Paris in 1718, by Montfaucon.

CHRYSTAL. See **CRYSTAL**.

CHUB, or **CHUBB**, in ichthyology. See **CYPRINUS**.

CHUBB (Thomas), a noted polemical writer, born at Eaft Harnham, a village near Salisbury, in 1679. He was put apprentice to a glover at Salisbury, and afterwards entered into partnership with a tallow-chandler. Being a man of ftrong natural parts, he employed all his leifure in reading; and though a ftranger to the learned languages, became tolerably verfed in geography, mathematics, and other branches of fcience. His favourite ftudy was divinity; and he formed a little fociety for the purpofe of debating upon religious fubjects, about the time that the Trinitarian controverfy was fo warmly agitated between Clarke and Waterland. This fubject therefore falling under the cognizance of Chubb's theological afsembly, he at their request drew up and arranged his fentiments on it, in a kind of differtation; which was afterward published under the title of *The Supremacy of the Father asserted*, &c. In this piece Mr Chubb fhewed great talents in reafoning; and acquired fo much reputation, that the late Sir Jofeph Jekyl, mafter of the rolls, took him into his family to enjoy his converfation: but though he is faid to have been tempted to remain with him by the offer of a gentle allowance, he did not continue with him many years; but chofe to return to his friends at Salisbury. He published afterward a 4^{to} volume of trafts, which Mr Pope informs his friend Gay, he "read through with admiration of the writer, though not always with approbation of his doctrine." He died a fingle man in the 68th year of his age, and left behind him 2 vols. of pofthumous trafts, in which he appears to have had little or no belief in revelation. But however licentious his way of thinking may be deemed, nothing irregular

Chryfal
Chubb.

Chudleigh
Church.

irregular or immoral has been fairly imputed to him in his life and actions.

CHUDLEIGH (Lady Mary), was born in 1656, and married to Sir George Chudleigh, bart. by whom she had several children : her poems and essays have been much admired for delicacy of style. She died in 1710 ; and is said to have written several dramatic pieces, which, though not printed, are preserved in the family.

CHUPMESSAHITES, a sect among the Mahomans, who believe that Jesus Christ is God, and the true Messiah, the Redeemer of the world ; but without rendering him any public or declared worship. The word, in the Turkish language, signifies *protector of the Christians*. Ricaut says, there are abundance of these *Chupmessahites* among the people of fashion in Turkey, and some even in the seraglio.

CHURCH, has different significations, according to the different subjects to which it is applied.

1. It is understood of the collective body of Christians, or all those over the face of the whole earth who profess to believe in Christ, and acknowledge him to be the Saviour of mankind. This is what the ancient writers call the catholic or universal church. Sometimes the word church is considered in a more extensive sense, and divided into several branches ; as the church militant, is the assembly of the faithful on earth ; the church triumphant, that of the faithful already in glory ; to which the Papists add the church patient, which, according to their doctrines, is that of the faithful in purgatory.

2. Church is applied to any particular congregation of Christians, who associate together and concur in the participation of all the institutions of Jesus Christ, with their proper pastors and ministers. Thus we read of the church of Antioch, the church of Alexandria, the church of Thessalonica, and the like.

3. Church denotes a particular sect of Christians distinguished by particular doctrines and ceremonies. In this sense, we speak of the Romish church, the Greek church, the Reformed church, the church of England, &c.

The Latin or Western church, comprehends all the churches of Italy, France, Spain, Africa, the north, and all other countries whither the Romans carried their language. Great Britain, part of the Netherlands, of Germany, and of the North, have been separated from hence ever since the time of Henry VIII. ; and constitute what we call the Reformed church, and what the Romanists call the Western schism.

The Greek or Eastern church, comprehends the churches of all the countries anciently subject to the Greek or eastern empire, and through which their language was carried ; that is, all the space extended from Greece to Mesopotamia and Persia, and thence into Egypt. This church has been divided from the Roman, ever since the time of the emperor Phocas.

The Gallican church, denotes the church of France, under the government and direction of their respective bishops and pastors. This church has always enjoyed certain franchises and immunities ; not as grants from popes, but as derived to her from her first original, and which she has taken care never to relinquish. These liberties depend upon two maxims ; the first,

that the pope has no authority or right to command or order any thing either in general, or in particular, in which the temporalities and civil rights of the kingdom are concerned ; the second, that notwithstanding the pope's supremacy is owned in cases purely spiritual, yet in France his power is limited and regulated by the decrees and canons of ancient councils received in that realm.

4. The word church is used to signify the body of ecclesiastics, or the clergy, in contradistinction to the laity. See **CLERGY**.

5. Church is used for the place where a particular congregation or society of Christians assemble for the celebration of divine service. In this sense churches are variously denominated, according to the rank, degree, discipline, &c. as Metropolitan church, Patriarchal church, Cathedral church, Parochial church, Collegiate church, &c. See **METROPOLIS**, **PATRIARCH**, &c.

CHURCH-ALS. See **WHITSUN-ALS**.

CHURCH-REEVES, the same with **CHURCH-WARDENS**.

CHURCH-SCOT, or **CHURCHESSET**, a payment, or contribution, by the Latin writers frequently called *primitiæ fœminum* ; being, at first, a certain measure of wheat, paid to the priest on St Martin's day, as the first-fruits of harvest. This was enjoined by the laws of king Malcolm IV. and Canute, c. 10. But after this, *Church-scot* came to signify a reserve of corn not paid to the secular priests, or to the religious ; and sometimes was taken in so general a sense as to include poultry, or any other provision that was paid in kind to the religious. See **TITHES**.

CHURCH-WARDENS, (ecclesiæ guardiani), in the English ecclesiastical polity, are the guardians or keepers of the church, and representatives of the body of the parish. They are sometimes appointed by the minister, sometimes by the parish, sometimes by both together, as custom directs. They are taken, in favour of the church, to be, for some purposes, a kind of corporation at the common law ; that is, they are enabled, by that name, to have a property in goods and chattels, and to bring actions for them, for the use and profit of the parish. Yet they may not waste the church goods, but may be removed by the parish, and then called to account by actions at common law : but there is no method of calling them to account but by first removing them ; for none can legally do it but those who are put in their place. As to lands, or other real property, as the church, church-yard, &c. they have no sort of interest therein ; but if any damage is done thereto, the parson only or vicar shall have the action. Their office also is to repair the church, and make rates and levies for that purpose : but these are recoverable only in the ecclesiastical courts. They are also joined with the overseers in the care and maintenance of the poor. They are to levy a shilling forfeiture on all such as do not repair to church on Sundays and holidays ; and are empowered to keep all persons orderly while there ; to which end it has been held that a church-warden may justify the pulling off a man's hat, without being guilty of either an assault or a trespass. There are also a multitude of other petty parochial powers committed to their charge by divers acts of Parliament.

CHURCH-YARD, a piece of ground adjoining to a church,

Churchill. church, set apart for interment or burial of the dead. —In the church of Rome they are blessed or consecrated with great solemnity. If a church-yard which has been thus consecrated, shall afterwards be polluted by any indecent action, or profaned by the burial of an infidel, an heretic, an excommunicated or unbaptized person, it must be *reconciled*; and the ceremony of the reconciliation is performed with the same solemnity as that of the blessing or consecration.

CHURCHILL (Sir Winston) the father of the great duke of Marlborough, was descended from an ancient and honourable family in Dorsetshire. He was born at Wotton Glanville in that county, in 1610; and educated at St John's college at Oxford. He engaged in the cause of his unfortunate sovereign Charles I. for which he suffered severely in his fortune; and having married, while young, Elizabeth, the daughter of Sir John Drake of Ash in Devonshire, he was forced to seek a refuge in her father's house, when Mr Churchill's misfortunes left him none that he could call his own; and there most of his children were born. After the restoration, he was elected a burgess to serve in parliament for the borough of Weymouth; and, in 1669, his majesty was pleased to confer on him the honour of knighthood. The next year he was made one of the commissioners of claims in Ireland; and upon his return from thence, was constituted one of the clerks controllers of the green-cloth: but writing a kind of political essay upon the History of England, which gave great offence to the parliament, he was, in 1678, dismissed from his post. He was, however, soon restored to it again; and lived to see his eldest surviving son raised to the peerage, and the rest of his children in a fair way to promotion. He died in 1688.

CHURCHILL (John) duke of Marlborough, and prince of the holy Roman empire; a most renowned general and statesman, was born at Ash in Devonshire in 1650. He was eldest son of Sir Winston Churchill*, who carried him to court while very young, and where he was particularly favoured by James duke of York, afterwards king James II. when only twelve years of age. In 1666, he was made an ensign of the guards during the first Dutch war; and afterwards improved himself greatly in the military art at Tangier. In 1672, Mr Churchill attended the duke of Monmouth who commanded a body of auxiliaries in the French service, and was soon after made a captain in the duke's own regiment. At the siege of Nimeguen, which happened in that campaign, he distinguished himself so much that he was taken notice of by the celebrated marshal Turenne, who bestowed on him the name of the *handsome Englishman*.—In 1673, he was at the siege of Maelbricht, where he gained such applause, that the king of France made him a public acknowledgement of his service; and the duke of Monmouth, who had the direction of the attack, told king Charles II. that he owed his life to Mr Churchill's bravery. In 1681, he married Sarah daughter and co-heiress (with her sister the countess of Tyrconnel) of Richard Jennings Esq; of Sandrich, in Hertfordshire. The duke of York recommended him in a very particular manner to the king; who, in 1682, created him baron of Eymouth in the county of Berwick in Scotland, and made him colonel of the third troop of

guards. A little after king James's accession, he was created baron Churchill of Sandrich in the county of Hertford, and made brigadier-general of his majesty's army in the west; where, when the duke of Monmouth came to surprise the king's army, while the earl of Feversham and the majority of the officers were in their beds, he kept the enemy in play, till the king's forces had formed themselves, and thereby saved the whole army. When James shewed an intention of establishing the catholic religion in Britain, lord Churchill, notwithstanding the great obligations he owed him, thought it his duty to abandon the royal cause; but even then did not leave him without acquainting him by letter with the reason of his doing.—Lord Churchill was graciously received by the prince of Orange; and was by him employed first to re-assemble the troop of guards at London; and afterwards to reduce some lately raised regiments, and to new-model the army: for which purpose he was invested with the rank and title of lieutenant-general. In 1689, he was sworn one of the privy council, and one of the gentlemen of the king's bed-chamber; and on the 9th of April following, was raised to the dignity of earl of Marlborough in the county of Wilts. He assisted at the coronation of their majesties; and was soon after made commander in chief of the English forces sent over to Holland; and here he first laid the foundation of that fame which was afterwards spread over all Europe. In 1690, he was made general of the forces sent to Ireland; where he made the strong garrisons of Cork and Kinsale prisoners of war. The year following, king William shewed the good opinion he had of his conduct, by sending him to Flanders to put all things in readiness, and to draw the army together against his arrival. In 1692, he was dismissed from all his employments; and, not long after, was with some other peers committed to the tower on an accusation of high treason; which, however, was afterwards found to be a false and malicious report, the authors of which were punished. Marlborough was soon restored to favour, and in 1698, was appointed governor to the earl of Gloucester; with this extraordinary compliment from king William, "My lord, make him but what you are, and my nephew will be all I wish to see him." The same day he was again sworn one of the privy council; and in July following was declared one of the lords justices of England, for the administration of the government, in which great trust he was three times successively in the king's absence, who in 1701 appointed him general of the foot, commander in chief of the English forces, and ambassador extraordinary and plenipotentiary at the Hague. Upon the accession of queen Anne to the throne, he was elected into the order of the garter, declared captain-general of all her majesty's forces, and sent ambassador extraordinary and plenipotentiary to Holland. After several conferences about a war, he put himself at the head of the army, where all the other generals had orders to obey him. His exploits in the field have been taken notice of under the article BRITAIN, n^o 348 —366: we shall therefore only take notice in this place, of the rewards and honours conferred upon him for these exploits. After his first campaign he was created marquis of Blandford and duke of Marl-

borough,

* See the foregoing article.

Churchill. borough, with a pension of L. 5000 for life, out of the post-office. In 1703, he met Charles III. late emperor going to Spain, who presented him with a sword set with diamonds. In 1704, having forced the enemy's lines at Schellenberg, he received a letter of thanks from the emperor Leopold, written with his own hand, an honour seldom done to any but sovereign princes. After the battle of Blenheim, he received congratulatory letters from most of the potentates in Europe, particularly from the States General, and from the emperor, who desired him to accept of the dignity of a prince of the empire, which with the queen's leave was conferred upon him by the title of "Prince of Mildenheim in the province of Swabia." After the campaign was ended, he visited the court of Prussia, where he laid such schemes as suspended the disputes with the Dutch about king William's estate, which wife conduct caused the whole confederacy to acknowledge that he had done the greatest service possible to the common cause. Upon his return to England, the queen, to perpetuate his memory, granted the interest of the crown in the honour and manor of Woodstock and hundred of Wotton to him and his heirs for ever. In 1705, he made a tour to Vienna, upon an invitation of the emperor Joseph; who highly caressed him, and made him a grant of the lordship of Mildenheim. After the campaign of 1708, the speaker of the house of commons was sent to Brussels on purpose to compliment him; and on his return to England he was again complimented in the house of lords by lord chancellor Cowper. All his services, however, and all the honours conferred upon him, were not sufficient to preserve him from being disgraced. After the change of the ministry in 1710, his interest daily declined; and in 1712, on the first day of the new year, he was removed from all his places. Finding all arts used to render him obnoxious in his native country, he visited his principality of Mildenheim, and several towns in Germany; after which he returned to England, and arrived there on the day of the queen's death. After being welcomed by the nobility and foreign ministers, he attended on king George I. in his public entry through London, who appointed him captain-general, colonel of the first regiment of foot-guards, one of the commissioners for the government of Chelsea hospital, and master-general of the ordnance. Some years before his death, he retired from public business. He died at Windsor lodge in 1722, aged 72; and was buried with great pomp in king Henry VIIth's chapel in Westminster Abbey.

CHURCHILL (Charles), a celebrated satirist, the son of Mr Charles Churchill, curate and lecturer of St John's, Westminster, was educated at Westminster school, and received some applause for his abilities from his tutors in that famous seminary. His capacity, however, was greater than his application, so that he acquired the character of a boy that could do good if he would. As the slightest accounts of persons so noted are agreeable, it may not be amiss to observe, that having one day got an exercise to make, and from idleness or inattention having failed to bring it at the time appointed, his master thought proper to chastise him with some severity, and even reproached his stupidity: what the fear of stripes could not effect,

the fear of shame soon produced, and he brought his exercise the next day, finished in such a manner, that he received the public thanks of all the masters. Still, however, his progress in the learned languages was but slow; nor is it to be wondered at, if we consider how difficult it was for a strong imagination, such as he was possessed of, to conform and walk tamely forward in the trammels of a school education: minds like his are ever starting aside after new pursuits; desirous of embracing a multiplicity of amusing objects; eager to come at the end, without the painful investigation of the means. In short, for want of proper skill in these languages, he was rejected from Oxford, whither his father had sent him; and probably this might have given occasion to the frequent invectives we find in his works against that most respectable university. Upon his return from thence, he again applied to his studies in Westminster school, where, at 17 years of age, he contracted an intimacy with a lady, to whom he was married, and their mutual regard for each other continued for several years. At the usual age of going into orders, Mr Churchill was ordained by the late bishop of London, and obtained a small curacy in Wales of thirty pounds a year. Thither he carried his wife; they took a small house; and he passed through the duties of his station with assiduity and cheerfulness. Happy had it been for him had he continued there to enjoy the fruits of piety, peace, and simplicity of manners. He was beloved and esteemed by his parishioners; and though his sermons were rather above the level of his audience, they were commended and followed. But endeavouring to advance his fortune, by keeping a cyder cellar, it involved him in difficulties which obliged him to leave Wales and come to London. His father dying soon after, he stepped into the church in which he had officiated; and, in order to improve his income, which scarcely produced an hundred pounds a year, he taught young ladies to read and write English at a boarding-school, kept by Mrs Dennis, where he behaved with that decency and decorum which became his profession. His method of living, however, bearing no proportion to his income, he contracted several debts in the city; which being unable to pay, a jail, the terror of indigent genius, seemed ready to complete his misfortunes: but from this state of wretchedness he was relieved by the benevolence of Mr Lloyd, father to the poet of that name. Mean while, Mr Lloyd, the son, wrote a poetical epistle called the *Altor*; which being read and approved by the public, gave the author a distinguished place among the writers of his age. This induced Mr Churchill to write the *Rosciad*. It first came out without the author's name; but the justness of the remarks, and the severity of the satire, soon excited public curiosity. Though he never disowned his having written this piece, and even openly gloried in it; yet the public, unwilling to give so much merit to one alone, ascribed it to a combination of wits: nor were Messrs Lloyd, Thornton, or Colman, left unnamed upon this occasion. This misplaced praise soon induced Mr Churchill to throw off the mask, and the second edition appeared with his name at full length. As the *Rosciad* was the first of this poet's performances,

Churchill.

Churchill.

performances, so many are of opinion that it is the best. In it we find a very close and minute discussion of the particular merit of each performer; their defects pointed out with candour, and their merits praised without adulation. This poem, however, seems to be one of those few works which are injured by succeeding editions: when he became popular, his judgment began to grow drunk with applause; and we find, in the latter editions, men blamed whose merit is incontestible, and others praised that were at that time in no degree of esteem with the judicious.

His next performance was his *Apology to the Critical Reviewers*. This work is not without its peculiar merit; and as it was written against a set of critics whom the world was willing enough to blame, the public read it with their usual indulgence. In this performance, he shewed a particular happiness of throwing his thoughts, if we may so express it, into poetical paragraphs; so that the sentence swells to the break or conclusion, as we find in prose.

But while his writings amused the town, his actions disgusted it. He now quitted his wife with whom he had cohabited many years; and resigning his gown and all clerical functions, commenced a complete *man of the town*, got drunk, frequented stewes; and, giddy with false praise, thought his talents a sufficient atonement for all his follies. In some measure to palliate the absurdities of his conduct, he now undertook a poem called *Night*, written upon a general subject indeed, but upon false principles; namely, that whatever our follies are, we should never attempt to conceal them. This, and Mr Churchill's other poems, being shown to Mr Johnson, and his opinion being asked, he allowed them but little merit; which being told to the author, he resolved to requite this private opinion with a public one. In his next poem, therefore, of the *Ghost*, he has drawn this gentleman under the character of Pomposo; and those who disliked Mr Johnson, allowed it to have merit. Mr Johnson's only reply to Churchill's abuse was, "that he thought him a shallow fellow in the beginning, and could say nothing worse of him still." The poems of *Night* and the *Ghost* had not the rapid sale the author expected; but his prophecy of *Famine* soon made ample amends for the late paroxysm in his fame. In this piece, written in the spirit of the famous North Briton, he exerted his virulent pen against the whole Scots nation; adopting the prejudices of the mob, and dignifying scurrility by the aid of a poetic imagination. It had a rapid and extensive sale, as prophesied by Mr Wilkes; who said, before its publication, that he was sure it must take, as it was at once personal, poetical, and political. After its appearance, it was even asserted by his admirers, that Mr Churchill was a better poet than Pope. This exaggerated adulation, as it had before corrupted his morals, began now to impair his mind: several succeeding pieces were published, which, being written without effort, are read without pleasure. His *Gothom*, *Independence*, *The Times*, seem merely to have been written by a man who desired to avail himself of the avidity of the public curiosity in his favour, and are rather aimed at the pockets than the hearts of his readers.

Church-
yard
Cibber.

Mr Churchill died in 1764, of a miliary fever, with which he was seized at Boulogne in France, whither he had gone on a visit to Mr Wilkes. After his death his poems were collected and printed together in two volumes 8vo.

CHURCHYARD (Thomas), a poet who flourished in the reigns of Henry VIII. Edward VI. queen Mary and queen Elizabeth, was born at Shrewsbury; and inherited a fortune, which he soon exhausted in a fruitless attendance on the court, by which he only gained the favour of being retained a domestic in the family of lord Surrey; when, by his lordship's encouragement, he commenced poet. Upon his patron's death, he betook himself to arms; was in many engagements; was frequently wounded, and was twice made prisoner. He published 12 pieces, which he afterwards printed together in one volume, under the title of *Churchyard's Chips*; and also the tragedy of Thomas Mowbray duke of Norfolk. He died in 1570.

CHYLE, in the animal oeconomy, a milky fluid secreted from the aliments by means of digestion. See ANATOMY, n° 366,—371.

CHYLIFICATION, the formation of the chyle, or the act whereby the food is changed into chyle.

The chyle has by some authors been thought to have a great resemblance in its nature and chemical analysis to milk. The subject however, hath as yet, been but little inquiry into. See the article MILK.

CHYME, or CHYMUS, in the common signification of the word, denotes every kind of humour which is incrassated by concoction; under which notion it comprehends all the humours fit or unfit for preserving and nourishing the body, whether good or bad. It frequently imports the finest part of the chyle, when separated from the faeces, and contained in the lacteal and thoracic duct.

CHYMISTRY. See CHEMISTRY.

CHYMOLOGY, an appellation given to such naturalists as have employed their time in investigating the properties of plants from their taste and smell.

CHYMOSIS, in medicine, the act of making or preparing CHYME.

CHYMOSIS is also a distortion of the eye-lids, arising from an inflammation; also an inflammation of the tunica cornea in the eye.

CIBBER (Colley), a celebrated comedian, dramatic writer, and poet laureat to the king, was born at London in 1671. His father Caius Gabriel Cibber, was a native of Holstein, and a skilful statuary, who executed the basso relievo on the pedestal of the monument, and the two admired figures of lunatics over the piers of the gate to Bethlehem Hospital in Moorfields. Colley, who derived his Christian name from the surname of his mother's family, was intended for the church, but betook himself to the stage, for which he conceived an early inclination; and he was some time before he acquired any degree of notice, or even a competent salary. His first essay in writing, was the comedy of *Love's last Shift*, acted in 1695, which met with success; as did his own performance of the character of the fop in it. From that time, as he says himself, "My muse and my spouse were so equally prolific, that the one was seldom the mother of a child, but in the same year the other made
me

me the father of a play. I think we had a dozen of each sort between us; of both which kinds some died in their infancy, and near an equal number of each were alive when we quitted the theatre." The *Carleſs Huſband*, acted in 1704, met with much applauſe, and is reckoned his beſt play: but none was of more importance to him than the *Non-juror*, acted in 1717, and levelled againſt the Jacobites. This laid the foundation of the miſunderſtanding between him and Mr Pope, raiſed him to be the hero of the *Dunciad*, and made him poet laureat in 1730. He then quitted the ſtage, except a few occaſional performances; and died in 1757. Cibber neither ſucceeded in acting nor in writing tragedy; and his odes were not thought to partake of the genius or ſpirit he ſhewed in his comedies.

His ſon *Theophilus*, alſo a comic actor after him, was born during a great ſtorm in 1703; and after paſſing a life of extravagance, diſtreſs, and perplexity, perished in another ſtorm in 1757, in the paſſage between Dublin and England. *Theophilus* married the ſiſter of Thomas Auguſtin Arne, the famous muſical compoſer; who became a celebrated tragic actorſs, and whoſe honour was ſacrificed to her huſband's extravagance.

CIBDELOPLACIA, in natural hiſtory, a genus of ſpars deſtroyed by a very large admixture of earth: they are opaque, formed of thin cruſts, covering vegetables and other bodies, by way of incruſtations.

Of this genus we have the following ſpecies: 1. A greyiſh-white one, with a rough ſurface. 2. A whitish-brown one: both theſe are friable. 3. A hard, pale-brown kind, which is the *offecolla* of the ſhops. 4. The whitish-grey kind, with a ſmooth ſurface: this is the *unicornu foſſile* and *ceratites* of authors. 5. The whitish-ſhiny *coralloide* kind.

CIBDELOSTRACIA, in natural hiſtory, terrene ſpars, deſtitute of all brightneſs and tranſparency, formed into thin plates, and uſually found coating over the ſides of hiſſures, and other cavities of ſtones, with congeries of them of great extent, and of plain or botryoid ſurfaces.

Of theſe there are uſually reckoned ſeven kinds: the firſt is the hard, browniſh-white *cibdeloſtracium*, found in Germany: the ſecond is the hard, whitish *cibdeloſtracium*, with thin cruſts, and a ſmoother ſurface, found alſo in the Harts-foreſt in Germany: the third is the hard, pale-brown *cibdeloſtracium*, with numerous very thin cruſts, found in ſubterranean caverns in many parts of England as well as Germany: the fourth is the white, light, and friable *cibdeloſtracium*, found alſo in Germany, but very rarely in any part of England: the fifth is the light, hard, pale-brown *cibdeloſtracium*, with a ſmooth ſurface, found in almoſt all parts of the world: the ſixth is the whitish, friable, cruſtaceous *cibdeloſtracium*, with a rougher ſurface, frequent in Germany and England; and the ſeventh is the browniſh-white, friable *cibdeloſtracium*, with a duſty ſurface, found in ſeveral parts of Ireland, as well as Germany.

CICADA, or **AMERICAN LOCUST**, in zoology, a genus of inſects belonging to the order of hemiptera. The beak is inflected; the antennæ are ſetaceous; the four wings are membranaceous and deſlected; and the feet, in moſt of the ſpecies, are of the jumping kind.

The ſpecies are fifty-one. The larvæ of ſeveral of this genus evacuate great quantities of a frothy matter upon the branches and leaves of plants, in the middle of which they conſtantly reſide. See *FROTH-SPIT*, and *CICADULA*.

CICADULA, in natural hiſtory, the name given by Mr Ray to a ſmall ſpecies of the above, called by Swammerdam *Ioculla pulex*, and found in May and June on the ſtalks and leaves of plants, involved in a ſpumeous white matter, commonly called cuckow-spit, or froth-spit. See *FROTH-SPIT*.

CICATRICULA, among natural hiſtorians, denotes a ſmall whitish ſpeck in the yolk of an egg, ſuppoſed to be the firſt rudiments of the future chick.

CICATRIX, in ſurgery, a little ſeam or elevation of callous fleſh riſing on the ſkin, and remaining there after the healing of a wound or ulcer. It is commonly called a ſcar.

CICATRIZANTS, in pharmacy, medicines which aſſiſt nature to form a cicatrix. Such are Armenian bole, powder of tutty, *deſiccativum rubrum*, &c.

Cicatrizants are otherwiſe called eſcharotics, epulotics, incarnatives, agglutinants, &c.

CICELY. See *MYRRHIS*.

CICER, or **CHICK-PEA**; a genus of the decandria order, belonging to the diadelphia claſs of plants. There is but one ſpecies, which produces peaſe ſhaped like the common ones, but much ſmaller. They are much cultivated in Spain, where they are natives, being one of the ingredients in their olios; as alſo in France; but are rarely known in Britain.

CICERO (Marcus Tullius,) the celebrated Roman orator, was born in the year of Rome 647, about 107 years before Chriſt. His father Marcus Tullius, who was of the equeſtrian order, took great care of his education, which was directed particularly with a view to the bar. Young Tully, at his firſt appearance in public, declaimed with ſuch vehemence againſt Sylla's party, that it became expedient for him to retire into Greece; where he heard the Athenian orators and philoſophers, and greatly improved both in eloquence and knowledge. Here he met with M. Pomponius who had been his ſchool-fellow; and who, from his love to Athens, and ſpending a great part of his days in it, obtained the ſurname of *Atticus*; and here they revived and confirmed that noted frienſhip which ſubſiſted between them through life, with ſo celebrated a conſtancy and affection. From Athens he paſſed into Aſia; and after an excursion of two years came back again into Italy.

Cicero was now arrived at Rome; and, after one year more ſpent at the bar, obtained, in the next place, the dignity of queſtor. Among the cauſes which he pleaded before his queſtorſhip, was that of the famous comedian Roſcius, whom a ſingular merit in his art had recommended to the familiarity and frienſhip of the greateſt men in Rome. The queſtors were the general receivers or treaſurers of the republic, and were ſent annually into the provinces diſtributed to them, as they always were, by lot. The iſland of Sicily happened to fall to Cicero's ſhare; and that part of it, for it was conſiderable enough to be divided into two provinces, which was called *Lilybæum*. This office he received not as a gift, but a truſt; and

Cicero.

he acquitted himself so well in it, that he gained the love and admiration of all the Sicilians. Before he left Sicily, he made the tour of the island, to see every thing that was curious, and especially the city of Syracuse; where he discovered the tomb of Archimedes to the magistrates who were hewing him the curiosities of the place, but who, to his surprise, knew nothing of any such tomb.

We have no account of the precise time of Cicero's marriage with Terentia; but it is supposed to have been celebrated immediately after his return from his travels to Italy, when he was about 30 years old. He was now disengaged from his quaestorship in Sicily, by which first step in the legal gradation and ascent of public honours, he gained an immediate right to the senate, and an actual admission into it during life; and settled again in Rome, where he employed himself constantly in defending the persons and properties of its citizens, and was indeed a general patron. Five years were almost elapsed since Cicero's election to the quaestorship, which was the proper interval prescribed by law, before he could hold the next office of ædile; to which he was now, in his 37th year, elected by the unanimous suffrages of all the tribes, and preferably to all his competitors. After Cicero's election to the ædileship, but before his entrance upon the office, he undertook the famed prosecution of C. Verres, the late prætor of Sicily; who was charged with many flagrant acts of injustice, rapine, and cruelty, during his triennial government of that island. This was one of the most memorable transactions of his life; for which he was greatly and justly celebrated by antiquity, and for which he will, in all ages, be admired and esteemed by the friends of mankind. The result was, that, by his diligence and address, he so confounded Hortensius, though the reigning orator at the bar, and usually styled the *king of the forum*, that he had nothing to say for his client. Verres, despairing of all defence, submitted immediately, without expecting the sentence, to a voluntary exile; where he lived many years, forgotten and deserted by all his friends. He is said to have been relieved in this miserable situation by the generosity of Cicero; yet was proscribed and murdered after all by Mark Antony, for the sake of those fine statues and Corinthian vessels of which he had plundered the Sicilians.

After the usual interval of two years from the time of his being chosen ædile, Cicero offered himself a candidate for the prætorship; and, in three different assemblies convened for the choice of prætors, two of which were dissolved without effect, he was declared every time the first prætor by the suffrages of all the centuries. He was now in the career of his fortunes; and in sight, as it were, of the consulship, the grand object of his ambition: and therefore, when his prætorship was at an end, he would not accept any foreign province, the usual reward of that magistracy, and the chief fruit which the generality proposed for it. He had no particular love for money, nor genius for arms, so that those governments had no charms for him: the glory which he pursued was to shine in the eyes of the city, as the guardian of its laws; and to teach the magistrates how to execute, the citizens how to obey, them.

Cicero.

Being now in his 43^d year, the proper age required by law, he declared himself a candidate for the consulship, along with six competitors, L. Sculpicius Galba, L. Sergius Catilina, C. Antonius, L. Calpurnius Longinus, Q. Cornificius, and C. Licinius Sacerdos. The two first were patricians; the two next plebeians, yet noble; the two last the sons of fathers who had first imported the public honours into their families: Cicero was the only *new man*, as he was called, among them, or one of equestrian rank. These were the competitors; and in this competition the practice of bribing was carried on as openly and as shamefully by Antonius and Catiline as it usually is at our elections in Britain. However, as the election approached, Cicero's interest appeared to be superior to that of all the candidates: for the nobles themselves, though always envious and desirous to depress him, yet out of regard to the dangers which threatened the city from many quarters, and seemed ready to burst out into a flame, began to think him the only man qualified to preserve the republic, and break the cabals of the desperate by the vigour and prudence of his administration. The method of choosing consuls was not by an open vote; but by a kind of ballot, or little tickets of wood distributed to the citizens, with the names of the several candidates inscribed upon each: but in Cicero's case the people were not content with this secret and silent way; but, before they came to any scrutiny, loudly and universally proclaimed Cicero the first consul: so that, as he himself says, "he was not chosen by the votes of particular citizens, but the common suffrage of the city; nor declared by the voice of the crier, but of the whole Roman people."

Cicero had no sooner entered upon his office, than he had occasion to exert himself against P. Servilius Rullus, one of the new tribunes, who had been alarming the senate with the promulgation of an Agrarian law; the purpose of which was to create a decemvirate, or ten commissioners, with absolute power for five years, over all the revenues of the republic, to distribute them at pleasure to the citizens, &c. These laws used to be greedily received by the populace, and were proposed therefore by factious magistrates as oft as they had any point to carry with the multitude against the public good; so that Cicero's first business was to quiet the apprehensions of the city, and to baffle, if possible, the intrigues of the tribune. Accordingly, in an artful and elegant speech from the rostra, he gave such a turn to the inclination of the people, that they rejected this law with as much eagerness as they had ever received one. But the grand affair of all, which constituted the glory of his consulship, and has transmitted his name with such lustre to posterity, was the skill he shewed, and the unwearied pains he took, in suppressing that horrid conspiracy which was formed by Catiline and his accomplices for the subversion of the commonwealth. For this great service he was honoured with the glorious title of *pater patriæ*, "the father of his country," which he retained for a long time after.

Cicero's administration was now at an end; but he had no sooner quitted his office, than he began to feel the weight of that envy which is the certain fruit of illustrious merit. He was now, therefore, the com-

mon

mon mark, not only of all the factions, against whom he had declared perpetual war, but of another party not less dangerous, the envious too : whose united spleen never left him from this moment till they had driven him out of that city which he had so lately preferred. Cicero, upon the expiration of his consulship, took care to send a particular account of his whole administration to Pompey, who was finishing the Mithridatic war in Asia ; in hopes to prevent any wrong impressions there from the calumnies of his enemies, and to draw from him some public declaration in praise of what he had been doing. But Pompey being informed by Metellus and Cæsar of the ill humour that was rising against Cicero in Rome, answered him with great coldness ; and instead of paying him any compliment, took no notice at all of what had passed in the affair of Catiline : upon which Cicero expostulates with him in a letter which is still extant.

About this time Cicero bought a house of M. Crassus on the Palatine-hill, adjoining to that in which he had always lived with his father, and which he is now supposed to have given up to his brother Quintus. The house cost him near £. 30,000, and seems to have been one of the noblest in Rome. It was built about 30 years before by the famous tribune M. Livius Drusus : on which occasion we are told, that when the architect promised to build it for him in such a manner that none of his neighbours should overlook him ; " But if you have any skill (replied Drusus) contrive it rather so that all the world may see what I am doing." The purchase of so expensive a house raised some censure on his vanity ; and especially as it was made with borrowed money. This circumstance he himself does not dissemble ; but says merrily upon it, that " he was now plunged so deeply in debt, as to be ready for a plot, only that the conspirators would not trust him."

The most remarkable event that happened in this year, which was the 45th of Cicero's life, was the pollution of the mysteries of the *bona dea* by P. Clodius ; which, by an unhappy train of consequences, involved Cicero in a great and unexpected calamity. Clodius, who had an intrigue with Cæsar's wife Pompeia, who, according to annual custom, was now celebrating in her house those awful sacrifices of the goddesses, to which no male creature ever was admitted ; and where every thing masculine was so scrupulously excluded, that even pictures of that sort were covered during the ceremony. It flattered Clodius's imagination greatly to gain access to his mistress in the midst of her holy ministry ; and with this view he dressed himself in a woman's habit, that by the benefit of his smooth face, and the introduction of one of the maids, he might pass without discovery : but by some mistake between him and his guide, he lost his way when he came within the house, and fell in unluckily among the other female servants. Here he was detected by his voice, and the servants alarmed the whole company by their shrieks, to the great amazement of the matrons, who threw a veil over their sacred mysteries, while Clodius found means to escape. The story was presently spread abroad, and raised a general scandal and horror throughout the

city. The whole defence which Clodius made, when, by order of the senate, he was brought to a trial, was to prove himself absent at the time of the fact ; for which purpose he produced two men to swear, that he was then at Interamna, about two or three days journey from the city. But Cicero, being called upon to give his testimony, deposed, that Clodius had been with him that very morning at his house in Rome. Irritated by this, Clodius formed a scheme of revenge. This was to get himself chosen tribune, and in that office to drive Cicero out of the city, by the publication of a law, which, by some stratagem or other, he hoped to obtrude upon the people. But as all patri-cians were incapable of the tribunate, by its original institution, so his first step was to make himself a plebeian, by the pretence of an adoption into a plebeian house, which could not yet be done without the suffrage of the people. The first triumvirate was now formed ; which was nothing else in reality but a traitorous conspiracy of three of the most powerful citizens of Rome, to extort from their country by violence what they could not obtain by law. Pompey's chief motive was to get his acts confirmed by Cæsar in his consulship, which was now coming on : Cæsar, by giving way to Pompey's glory, to advance his own ; and Crassus, to gain that ascendence by the authority of Pompey and Cæsar, which he could not sustain alone. Cicero might have made what terms he pleased with the triumvirate ; and been admitted even a partner of their power, and a fourth in their league : but he would not enter into any engagements with the three whose union he and all the friends of the republic abhorred. Clodius, in the mean time, had been pushing on the business of his adoption : which at last he effected ; and began soon after to threaten Cicero with all the terrors of his tribunate, to which he was now advanced without any opposition. Both Cæsar and Pompey secretly favoured his scheme : not that they intended to ruin Cicero, but only to keep him under the lash ; and if they could not draw him into their measures, or make him at least keep quiet, to let Clodius loose upon him. Cæsar, in particular, wanted to distress him so far as to force him to a dependence on himself : for which end, while he was privately encouraging Clodius to pursue him, he was proposing expedients to Cicero for his security. But though his fortunes seemed now to be in a tottering condition, and his enemies to gain ground daily upon him ; yet he was unwilling to owe the obligation of his safety to any man, far less to Cæsar, whose designs he always suspected, and whose schemes he never approved. This stiffness in Cicero so exasperated Cæsar, that he resolved immediately to assist Clodius with all his power to oppress him ; while Pompey was all the while giving him the strongest assurances that there was no danger, and that he would sooner be killed himself than suffer him to be hurt.

Clodius, in the mean time, was obliging the people with several new laws, contrived chiefly for their advantage ; the design of all which was only to introduce, with a better grace, the ground-plot of the play, the banishment of Cicero. In short, having caused a law to be enacted, importing, that any who had condemned a Roman citizen unheard should himself be

banished,

Cicero.

Cicero.

banished, he soon after impeached Cicero upon it. It was in vain that this great man went up and down the city soliciting his cause in the habit of a suppliant, and attended by many of the first young noblemen whom he had taught the rules of eloquence; those powers of speaking which had so often been successful in defending the cause of others, seemed totally to forsake his own: he was banished by the votes of the people 400 miles from Italy; his houses were ordered to be demolished, and his goods set up to sale. It cannot be denied, that in this great calamity he did not behave himself with that firmness which might reasonably be expected from one who had borne so glorious a part in the republic; conscious of his integrity, and suffering in the cause of his country: for his letters are generally filled with such lamentable expressions of grief and despair, that his best friends, and even his wife, were forced sometimes to admonish him to rouse his courage, and remember his former character. Atticus was constantly putting him in mind of it; and sent him word of a report, that was brought to Rome by one of Cassius's freed-men, that his affliction had disordered his senses. He was now indeed attacked in his weakest part; the only place in which he was vulnerable. To have been as great in affliction as he was in prosperity, would have been a perfection not given to man: yet this very weakness flowed from a source which rendered him the more amiable in all the other parts of his life; and the same tenderness of disposition which made him love his friends, his children, and his country, more passionately than other men, made him feel the loss of them more sensibly. When he had been gone a little more than two months, a motion was made in the senate by one of the tribunes, who was his friend, to recall him, and repeal the laws of Clodius; to which the whole house readily agreed. Many objections, as may be easily imagined, were given to it by the Clodian faction; but this made the senate only more resolute to effect it. They passed a vote therefore, that no other business should be done till Cicero's return was carried; which at last it was, and in so splendid and triumphant a manner, that he had reason, he says, to fear, lest people should imagine that he himself had contrived his late flight for the sake of so glorious a restoration.

Cicero, now in his 50th year, was restored to his former dignity, and soon after to his former fortunes; satisfaction being made to him for the ruin of his estates and houses; which last were built up again by himself with more magnificence than before. But he had domestic grievances about this time, which touched him very nearly; and which, as he signifies obscurely to Atticus, were of too delicate a nature to be expressed in a letter: They arose chiefly from the petulant humour of his wife, which began to give him frequent occasions of chagrin; and, by a series of repeated provocations, confirmed in him that settled disgust which at last ended in a divorce.

In the 56th year of his age, he was made proconsul of Cilicia; and his administration there gained him great honour. About this time the expectation of a breach between Cæsar and Pompey engaged the general attention. Crassus had been destroyed with

his army some years before in the war with the Parthians; and Julia, the daughter of Cæsar, whom Pompey married, and who, while she lived, was the cement of their union, was also dead in child-bed. Cæsar had put an end to the Gallic war, and reduced the whole province to the Roman yoke: but though his commission was near expiring, he seemed to have no thoughts of giving it up, and returning to the condition of a private subject. He pretended that he could not possibly be safe if he parted with his army; especially while Pompey held the province of Spain prolonged to him for five years. This disposition to a breach Cicero soon learned from his friends, as he was returning from his province of Cilicia. But as he foresaw the consequences of a war more clearly and fully than any of them, so his first resolution was to apply all his endeavours and authority to the mediation of a peace; though, in the event of a breach, he was determined within himself to follow Pompey. He clearly foresaw, what he declared without scruple to his friends, that which side ever got the better, the war must necessarily end in a tyranny. The only difference, he said, was, that, if their enemies conquered, they should be proscribed; if their friends, they would be slaves.

He no sooner arrived at the city, however, than he fell, as he tells us, into the very flame of civil discord, and found the war in effect proclaimed: for the senate had just voted a decree, that Cæsar should disband his army by a certain day, or be declared an enemy; and Cæsar's sudden march towards Rome effectually confirmed it. In the midst of all this hurry and confusion, Cæsar was extremely solicitous about Cicero; not so much to gain him, for that was not to be expected, as to prevail with him to stand neuter. He wrote to him several times to that effect; and employed all their common friends to press him with letters on that subject: all which was done; but in vain, for Cicero was impatient to be gone to Pompey. In the mean time, these letters give us a most sensible proof of the high esteem and credit in which Cicero flourished at this time in Rome; when, in a contest for empire, which force alone was to decide, we see the chiefs on both sides so solicitous to gain a man to their party, who had no peculiar skill in arms, or talents for war. Pursuing, however, the result of all his deliberations, he embarked at length to follow Pompey, who had been obliged to quit Italy some time before, and was then at Dyrrhachium; and arrived safely in his camp with his son, his brother, and his nephew, committing the fortunes of the whole family to the issue of that cause. After the battle of Pharsalia, in which Pompey was defeated, Cicero returned into Italy, and was afterwards received into great favour by Cæsar, who was now declared dictator the second time, and Mark Antony his master of horse. We may easily imagine, what we find indeed from his letters, that he was not a little discomposed at the thoughts of an interview with Cæsar, and the indignity of offering himself to a conqueror against whom he had been in arms: for though upon many accounts he had reason to expect a kind reception from Cæsar, yet he hardly thought his life, he says, worth begging; since what was given by a master,

far,

fler, might always be taken away again at pleasure. But at their meeting, he had no occasion to say or do any thing that was below his dignity : for Cæsar no sooner saw him than he alighted, ran to embrace him, and walked with him alone, conversing very familiarly for several furlongs.

Cicero was now in his 61st year, and forced at last to part with his wife Terentia ; whose humour and conduct had been long uneasy to him. She was a woman of an imperious and turbulent spirit : and though he had borne her perverseness in the vigour of health, and flourishing state of his fortunes ; yet, in a declining life, soured by a continual succession of mortifications from abroad, the want of ease and quiet at home was no longer tolerable to him. But he was immediately oppressed by a new and most cruel affliction, the death of his beloved daughter Tullia, who died in child-bed soon after her divorce from her third husband Dolabella. She was about 32 years old, at the time of her death ; and, by the few hints which are left of her character, appears to have been an excellent and admirable woman. She was most affectionately and piously observant of her father ; and, to the usual graces of her sex, having added the more solid accomplishments of knowledge and polite letters, was qualified to be the companion and delight of his age ; and was justly esteemed not only as one of the best, but the most learned, of the Roman ladies. His affliction for the death of this daughter was so great, that, to shun all company as much as he could, he removed to Atticus's house, where he lived chiefly in his library, turning over every book he could meet with on the subject of moderating grief. But finding his residence here too public, and a greater resort to him than he could bear, he retired to Astura, one of his seats near Antium ; a little island on the Latian shore, at the mouth of a river of the same name, covered with woods and groves cut into shady walks ; a scene of all others the fittest to indulge melancholy, and where he could give a free course to his grief. " Here (says he to Atticus) I live without the speech of man ; every morning early I hide myself in the thickest of the wood, and never come out till the evening. Next to yourself, nothing is so dear to me as this solitude ; and my whole conversation is with my books." Indeed his whole time was employed in little else than reading and writing during Cæsar's administration, which he could never cheerfully submit to ; and it was within this period, that he drew up one of the gravest of these philosophical pieces which are still extant in his works.

Upon the death of Cæsar, Octavius, his nephew and heir, coming into Italy, was presented to Cicero by Hirtius and Panfa ; with the strongest professions on the part of the young man, that he would be governed entirely by his direction. Indeed Cicero thought it necessary to cherish and encourage Octavius, if for nothing else yet to keep him at a distance from Antony ; but could not yet be persuaded to enter heartily into his affairs. He suspected his youth and want of experience ; and that he had not strength enough to deal with Antony ; and, above all, that he had no good disposition towards the conspirators. He thought it impossible he should ever be a friend to

them ; and was persuaded rather, that if ever he got the upper hand, his uncle's acts would be more violently enforced, and his death more cruelly revenged than by Antony himself. And when Cicero did consent at last to unite himself to Octavius's interests, it was with no other view but to arm him with a power sufficient to oppress Antony ; yet so checked and limited, that he should not be able to oppress the republic.

In the hurry of all these politics, he was still prosecuting his studies with his usual application ; and, besides some philosophical pieces, now finished his book of offices, or the duties of man, for the use of his son : A work admired by all succeeding ages as the most perfect system of heathen morality, and the noblest effort and specimen of what reason could do in guiding man through life with innocence and happiness. However, he paid a constant attention to public affairs ; missed no opportunities, but did every thing that human prudence could do for the recovery of the republic : for all that vigour with which it was making this last effort for itself, was entirely owing to his counsels and authority. This appears from those memorable Philippics which from time to time he published against Antony ; as well as from other monuments of antiquity. But all was in vain : for though Antony's army was entirely defeated at the siege of Modena, which made many people imagine that the war was at an end and the liberty of Rome established ; yet the death of the consuls Panfa and Hirtius in that action, gave the fatal blow to all Cicero's schemes, and was the immediate cause of the ruin of the republic.

Octavius having subdued the senate to his mind, marched towards Gaul to meet Antony and Lepidus ; who had already passed the Alps, and brought their armies into Italy, in order to have a personal interview with him ; which had been privately concerted for settling the terms of a triple league, and dividing the power and provinces of Italy among themselves. The place appointed for this interview was a small island about two miles from Bononia, formed by the river Rhenus which runs near that city. Here they met, and spent three days in a close conference to adjust the plan of their accommodation : and the last thing they adjusted was the list of a proscription which they were determined to make of their enemies. This, as the writers tell us, occasioned much difficulty and warm contests among them ; till each in his turn consented to sacrifice some of his best friends to the revenge and resentment of his colleagues. Cicero was at his Tusculan villa, when he first received the news of the proscription and of his being included in it. It was the design of the triumvirate to keep it a secret, if possible, to the moment of execution ; in order to surprise those whom they had destined to destruction, before they were aware of their danger, or had time to make their escape. But some of Cicero's friends found means to give him early notice of it ; upon which he set forward to the sea-side, with a design to transport himself out of the reach of his enemies. There, finding a vessel ready, he presently embarked ; but the winds being adverse, and the sea uneasy to him, after he had sailed about

Cicero
|
Cichorium.

two leagues along the coast, he was obliged to land, and spend the night on shore. From thence he was forced, by the importunity of his servants, on board again; but was soon afterwards obliged to land at a country-seat of his, a mile from the shore, weary of life, and declaring he was resolved to die in that country which he had so often saved: here he slept soundly for some time, till his servants once more forced him away in a litter towards the ship, having heard that he was pursued by Antony's assassins. They were scarce departed, when the assassins arrived at his house; and, perceiving him to be fled, pursued him immediately towards the sea, and overtook him in a wood that was near the shore. Their leader was one Popilius Lenas, a tribune of the army, whose life Cicero had formerly defended and saved. As soon as the soldiers appeared, the servants prepared to defend their master's life, at the hazard of their own; but Cicero commanded them to let him down and make no resistance. They soon cut off his head and his hands, returning with them to Rome, as the most agreeable present to their cruel employer. Antony, who was then at Rome, received them with extreme joy, rewarding the murderer with a large sum of money, and ordering the head to be fixed upon the rostra between the two hands: a sad spectacle to the city; and what drew tears from every eye, to see those mangled members which used to exert themselves so gloriously from that place, in defence of the lives, the fortunes, and the liberties of the Roman people, so lamentably exposed to the scorn of sycophants and traitors. The deaths of the rest, says an historian of that age, caused only a private and particular sorrow, but Cicero's an universal one. It was a triumph over the republic itself; and seemed to confirm and establish the perpetual slavery to Rome. Antony considered it as such; and, satisfied with Cicero's blood, declared the proscription at an end. Cicero was killed on the seventh of December, in the 64th year of his age, about ten days from the settlement of the first triumvirate.

CICHORIUM, succory; a genus of the polygama æqualis order, belonging to the syngenesia class of plants.

Species. 1. The intybus, or wild succory, grows naturally by the sides of roads, and in shady lanes in many places of Britain. It sends out long leaves from the roots, from between which the stalks arise, growing to the height of three or four feet, and branching out into smaller ones. The flowers come out from the sides of the stalks, and are of a fine blue colour. They are succeeded by oblong seeds covered, inclosed in a down. 2. The spinosum, with a prickly forked stalk, grows naturally on the sea-coasts in Sicily, and the islands of the Archipelago. This sends out from the root many long leaves which are indented on their edges, and spread flat on the ground; from between these arise the stalks, which have very few leaves, and those are small and entire: these stalks are divided in forks upward, and from between them come out the flowers which are of a pale blue colour and are succeeded by seeds shaped like those of the common forts. The ends of the smaller branches are terminated by star-like spines which are very sharp. 3. The

endivia, or succory with broad crenated leaves, differs *Cichorium*. from the wild fort in its duration, being only annual, whereas the wild fort is perennial.

Culture, &c. The last species may be considered both as an annual and biennial plant. If sown early in the spring, or even any time before the beginning of June, the plants very commonly fly up to seed the same summer, and perish in autumn. If sown in June and July, they acquire perfection in autumn, continue till the next spring, then shoot up stalks for flower and seed, and soon after perish. The inner leaves are the useful parts. These when blanched white to render them crisp and tender, and reduce them from their natural strong taste to an agreeably bitter one, are then fit for use. They are valued chiefly as ingredients in autumn and winter salads, and for some culinary uses. The principal season of them is from the latter end of August till Christmas or longer, according to the temperature of the season; though the curled kinds generally resist the frosts of our ordinary winters, and remain in tolerable perfection till March or April. They are propagated by seeds sown in an open spot of ground, from which the plants are to be removed into open beds or borders where they may remain to grow to full size. The season for sowing these seeds is from the beginning of June to the end of July; and to have a regular supply of plants, it is proper to perform three different sowings at about three weeks or a month's interval. The great excellence of endive is to have its inner leaves finely whitened or blanched. They naturally incline to whiteness of themselves, but this may be greatly improved by art when the plants are arrived at full growth. Different methods are practised for this purpose, such as tying the leaves together; taking up the plants, and replanting them directly, almost to their tops, in ridges of dry earth, laying boards or tiles flat-ways on the top of the plants; but the first is found to answer the purpose most effectually. The proper time for beginning this work is, when the leaves are almost full grown; that is, when they are so far advanced that the leaves of the different plants interfere with one another, and their hearts are full and bushy; but they are not all to be tied up at once, only a due supply of the largest and forwardest plants, once every ten or twelve days according to the demand; for the blanching takes up about three weeks. Blanching in ridges of earth, however, is sometimes practised in winter when a severe frost is setting in; for by burying them in the earth almost to their tops, they are more out of the power of the cold. In November or December, when hard weather is approaching, let a piece of light ground that lies warm, be trenched up in one or more sharp ridges two or three feet wide at bottom, and near as much in height, sideways to the sun, making the sides as steep as possible, that the wet may run quickly off; then, in a dry day, take up a quantity of your full grown plants, with their roots entire, and divesting them of damaged leaves, gather each plant close in your hand, placing them horizontally in the sunny-side of the ridge of earth almost to their tops, and about six or eight inches each way distant. In severe frost, it will be proper to bestow some covering on the plants.

Medicinal

Cicindela.

Cid.

Medicinal uses. The roots and leaves of the wild succory, and seeds of the endive, are articles of the *matéria medica*. The first has a moderately bitter taste, with some degree of roughness; the leaves are somewhat less bitter; and the darker coloured and more deeply jagged they are, the bitterer is their taste. Wild succory is an useful detergent, aperient, and attenuating medicine, acting without much irritation, tending rather to cool than to heat the body; and, at the same time, corroborating the tone of the intestines. All the parts of the plant, when wounded, yield a milky saponaceous juice. This, when taken in large quantities, so as to keep up a gentle diarrhoea, and continued for some weeks, has been found to produce excellent effects in scorbutic and other chronic disorders. The qualities of the endive are nearly of the same kind. The seeds are ranked among the four lesser cold ones.

CICINDELA, in zoology, a genus of insects belonging to the order of coleoptera. The antennae are setaceous; the jaws prominent, and furnished with teeth; the eyes are a little prominent; and the breast is roundish and margined. There are 14 species.

CICLUT, or CICLUGH, a strong frontier town of Dalmatia, situated on the river Narenta, in E. Long. 17. 40. N. Lat. 45. 20. It is surrounded with walls built in the ancient manner, and was taken by the Venetians from the Turks in 1694.

CICUTA, properly signifies an hollow intercepted between two knots, of the stalks or reeds of which the ancient shepherds used to make their pipes. It is now, however, generally used to signify the water hemlock, and also the common fort; but Linnæus has described the latter under the old name of *Centum*. See that article.

There are three species of water-hemlock; the virgata, the bulbifera, and the maculata. Of these the first is the only one remarkable, and that for the poisonous qualities of its roots, which have been often known to destroy children who eat them for parsnips.

CICUTA is also used, chiefly among the ancients, for the juice or liquor expressed from the above plant, being the common poison wherewith the state criminals at Athens were put to death: Though some have suggested, that the poisonous draught to which the Athenians doomed their criminals was an inspissated juice compounded of the juice of *cicuta*, and some other corrosive herbs.

Socrates drank the *cicuta*.—Plato, in his dialogue on the immortality of the soul, observes, that “The executioner advised Socrates not to talk, for fear of causing the *cicuta* to operate too slowly.” M. Petit, in his *Observations Miscellaneæ*, remarks, that this advertisement was not given by the executioner out of humanity, but to save the *cicuta*: for he was only allowed to much poison *per ann.* which, if he exceeded, he was to furnish at his own expence. This construction is confirmed by a passage in Plutarch: the executioner who administered the *cicuta* to Phocion, not having enough, Phocion gave him money to buy more; observing by the way, “that it was odd enough, that at Athens a man must pay for every thing, even his own death.”

CID (Roderigo Dias le), a Castilian officer, who

was very successful against the Moors, under Ferdinand II. king of Castile; but whose name would hardly have been remembered, if Corneille had not made his passion for Chimene the subject of an admired tragedy, founded on a simple but affecting incident. The Cid is desperately in love with Chimene, daughter of the Count de Gones: but he is at variance with the Count; and being challenged by him, kills him in a duel. The conflict between love and honour in the breast of Chimene, who at length pardons and marries the Cid, forms the beauty of the piece. He died in 1098.

CIDARIS, in antiquity, the mitre used by the Jewish high-priests. The Rabbins say, that the bonnet used by priests in general was made of a piece of linen cloth 16 yards long, which covered their heads like a helmet or turban; and they allow no other difference between the high-priest's bonnet and that of other priests, than that the one is flatter, and more in the form of a turban; whereas that worn by ordinary priests rose something more in a point.

CIGNANI (Carlo), an Italian painter, was born at Bologna in 1628; and was the disciple of Albani. He was esteemed by pope Clement XI. who nominated him prince of the academy of Bologna, and loaded him with favours. Cignani died at Forlì in 1719. The cupola of la Madonna del Fuoco at Forlì, in which he represented Paradise, is an admirable work. His principal pictures are at Rome, Bologna, and Forlì.

CILIA, the EYE-LASHES. See ANATOMY, II° 406. b, c.

CILIARE, or LIGAMENTUM CILIARE. *Ibid.* m. CILIATED LEAF, among botanical writers, one surrounded with parallel filaments somewhat like the hairs of the eye-lids.

CILICIA, an ancient kingdom of Asia, lying between the 36th and 40th degree of north latitude; bounded on the east by Syria, or rather by Mount Amanus, which separates it from that kingdom; by Pamphylia, on the west; by Isauria, Cappadocia, and Armenia Minor, on the north; and by the Mediterranean sea, on the south. It is so surrounded by steep and craggy mountains, chiefly the Taurus and Amanus, that it may be defended by a handful of resolute men against a numerous army, there being but three narrow passes leading into it, commonly called *Pyla Cilicia*, or the gates of Cilicia; one on the side of Cappadocia, called the *Pass of Mount Taurus*; and the other two called the *Pass of Mount Amanus*, and the *Pass of Syria*. The whole country was divided by the ancients into Cilicia Aspera, and Cilicia Campestris; the former called by the Greeks *Trachea* or *Stony*, from its abounding so with stones; and to this day, the whole province is called by the Turks, *Taa Wilaieth*, or the *Stony Province*.

According to Josephus, Cilicia was first peopled by Tarhish the son of Javan, and his descendants, whence the whole country was named *Tarshis*. The ancient inhabitants were in process of time driven out by a colony of Phœnicians, who, under the conduct of *Gelix*, first settled in the island of Cyprus, and from thence passed into the country which, from the leader, they called *Cilicia*. Afterwards, several other colonies from different nations settled in this kingdom,

Cidaris

Cilicia.

Cilicia. dom, particularly from Syria and Greece; whence the Cilicians in some places used the Greek tongue, in others the Syriac; but the former greatly corrupted by the Persian, the predominant language of the country being a dialect of that tongue. We find no mention of the kings of Cilicia after their settlement in that country, till the time of Cyrus, to whom they voluntarily submitted, continuing subject to the Persians till the overthrow of that empire; but governed to the time of Artaxerxes Mnemon, by kings of their own nation. After the downfall of the Persian empire, Cilicia became a province of that of Macedon; and, on the death of Alexander, fell to the share of Seleucus, and continued under his descendants till it was reduced to a Roman province by Pompey. As a proconsular province, it was first governed by Appian Claudius Pulcher; and after him by Cicero, who reduced several strong holds on Mount Amanus, in which some Cilicians had fortified themselves, and held out against his predecessor. It was on this occasion that the division, formerly mentioned, into Trachæa and Campestris, took place. The latter became a Roman province; but the former was governed by kings appointed by the Romans, till the reign of Vespasian, when the family of Tracondemonts being extinct, this part also made a province of the empire, and the whole divided into Cilicia *Prima*, Cilicia *Secunda*, and Isauria; the first took in all Cilicia Campestris, the second the coast of Cilicia Trachæa, and the last the inland parts of the same division. It is now a province of Asiatic Turkey; and is called *Guramania*, having been the last province of the Caramanian kingdom which held out against the Ottoman race.

That part of Cilicia called by the ancients *Cilicia Campestris*, was, if we believe Ammianus Marcellinus, one of the most fruitful countries of Asia; but the western part equally barren, though famous, even to this day, for an excellent breed of horses, of which 600 are yearly sent to Constantinople for the special use of the Grand Signior. The air in the inland parts is reckoned wholesome; but that on the sea-coast very dangerous, especially to strangers.

The rivers of any note are the Pyramus, which rises on the north side of mount Taurus, and empties itself into the Mediterranean between Iffus and Margarus; the Cydnus springs from the Antitaurus, passes through Tarsus, and disembogues itself into the Mediterranean. It is famous for the rapidity of its stream, and the coldness of its waters, which proved very dangerous to Alexander the Great.

The Cilicians, if we believe the Greek and Roman historians, were a rough unpolished race of people, unfair in their dealings, cruel, and liars even to a proverb. In the Roman times, they became greatly addicted to piracy. They first began, in the time of the Mithridatic war, to infect the neighbouring provinces along with the Pamphylans; and, being emboldened with success, they soon ventured as far as the coasts of Greece and Italy, where they took a vast number of slaves, whom they sold to the Cypriots and the kings of Egypt and Syria. They were, however, at last defeated and entirely suppressed by Pompey the Great. See (*History of*) ROME.

CILICIA *Terra*, in the natural history of the anti-

ents, a bituminous substance improperly called an earth, which, by boiling, became tough like bird-lime, and was used instead of that substance to cover the stocks of the vines for preserving them from the worms. It probably served in this office in a fort of double capacity, driving away these animals by its nauseous smell, and entangling them if they chanced to get amongst it.

CILICIUM, in Hebrew antiquity, a sort of habit made of coarse stuff, formerly in use among the Jews in times of mourning and distress. It is the same with what the Septuagint and Hebrew versions call sackcloth.

CILLEY, an ancient and famous town of Germany, in the circle of Austria, and in Upper Cariola. It is the capital of a county of the same name, and is situated on the river Saan, in E. Long. 15. 45. N. Lat. 46. 28.

CIMA, or SIMA, in architecture, the same with Cymatium, or OGEE.

CIMABUE (Giovani), a renowned painter, born at Florence in 1240, and the first who revived the art of painting in Italy. He painted, according to the custom of those times, in fresco, and in distemper; colours in oil not being then found out. He excelled in architecture as well as in painting; and was concerned in the fabric of Sancta Maria del Fior at Florence: during which employment he died at the age of 60, and left many disciples; among the rest Giotto, who proved an excellent master.

CIMBRI, an ancient Celtic nation, inhabiting the northern parts of Germany. They are said to have been descended from the Asiatic *Cimmerians*, and to have taken the name of *Cimbri* when they changed their old habitations. When they first became remarkable, they inhabited chiefly the peninsula now called *Jutland*, and by the ancients *Gimbrica Chersonesus*. About 113 years before Christ, they left their peninsula with their wives and children; and joining the Teutones, a neighbouring nation, took their journey southward in quest of a better country. They first fell upon the Boii, a Gaulish nation situated near the Hercynian forest. Here they were repulsed, and obliged to move nearer the Roman provinces. The republic being then alarmed at the approach of such multitudes of barbarians, sent an army against them under the consul Papirius Carbo. On the approach of the Roman army, the Cimbri made proposals of peace. The consul pretended to accept it; but having thrown them into a disadvantageous situation, treacherously attacked their camp. His perfidy was rewarded as it deserved; the Cimbri ran to arms, and not only repulsed the Romans, but, attacking them in their turn, utterly defeated them, and obliged the shattered remains of their forces to conceal themselves in the neighbouring forests. After this victory the Cimbri entered Transalpine Gaul, which they quickly filled with slaughter and desolation. Here they continued five or six years, when another Roman army under the consul Silanus marched against them. This general met with no better success than Carbo had done. His army was routed at the first onset; in consequence of which, all Narbonne Gaul was exposed at once to the ravages of these barbarians.

Cilicium
I
Cimbri.

Cimbri.

About 105 years before Christ, the Cimbri began to threaten the Roman empire itself with destruction. The Gauls marched from all parts with a design to join them, and to invade Italy. The Roman army was commanded by the proconsul Cæpio, and the consul Mallius; but as these two commanders could not agree, they were advised to separate, and divide their forces. This advice proved the ruin of the whole army. The Cimbri immediately fell upon a strong detachment of the consular army commanded by M. Aurelius Scaurus, which they cut off to a man, and made Scaurus himself prisoner. Mallius being greatly intimidated by this defeat, desired a reconciliation with Cæpio, but was haughtily refused. He moved nearer the consul, however, with his army, that the enemy might not be defeated without his having a share in the action. The Cimbri, by this movement, imagining the commanders had made up their quarrel, sent ambassadors to Mallius with proposals of peace. As they could not help going through Cæpio's camp, he ordered them to be brought before him; but finding they were empowered to treat only with Mallius, he could scarce be restrained from putting them to death. His troops, however, forced him to confer with Mallius about the proposals sent by the barbarians: but as Cæpio went to the consul's tent against his will, so he opposed him in every thing; contradicted with great obliquity, and insulted him in the grossest manner. The deputies on their return acquainted their countrymen that the misunderstanding between the Roman commanders still subsisted; upon which the Cimbri attacked the camp of Cæpio, and the Gauls that of Mallius. Both were forced, and the Romans slaughtered without mercy. Eighty thousand citizens and allies of Rome, with 40,000 servants and sutlers, perished on that fatal day. In short, of the two Roman armies only 10 men, with the two generals, escaped to carry the news of so dreadful a defeat. The conquerors destroyed all the spoil, pursuant to a vow they had made before the battle. The gold and silver they threw into the Rhone, drowned the horses they had taken, and put to death all the prisoners.

The Romans were thrown into the utmost consternation on the news of so terrible an overthrow. They saw themselves threatened with a deluge of Cimbri and Gauls, numerous enough to over-run the whole country. They did not, however, despair. A new army was raised with incredible expedition; no citizen whatever who was fit to bear arms being exempted. On this occasion also, fencing-masters were first introduced into the Roman camp, by which means the soldiers were soon rendered in a manner invincible. Marius, who was at that time in high reputation on account of his victories in Africa, was chosen commander, and waited for the Cimbri in Transalpine Gaul: but they had resolved to enter Italy by two different ways; the Cimbri over the eastern, and the Teutones and other allies over the western Alps. The Roman general therefore marched to oppose the latter, and defeated the Ambrones and Teutones with great slaughter*. The Cimbri, in the mean time, entered Italy, and struck the whole country with terror. Catulus and Sylla attempted to oppose them; but their soldiers were so intimidated by the fierce

countenances and terrible appearance of these barbarians, that nothing could prevent their flying before them. The city of Rome was now totally defenceless; and, had the Cimbri only marched briskly forwards, they had undoubtedly become masters of it; but they waited in expectation of being joined by their allies the Ambrones and Teutones, not having heard of their defeat by Marius, till the senate had time to recal him to the defence of his country. By their order he joined his army to that of Catulus and Sylla; and upon that union was declared commander in chief. The Roman army consisted of 52,300 men. The cavalry of the Cimbri were no more than 15,000, but their foot seemed innumerable; for, being drawn up in a square, they are said to have covered 30 furlongs. The Cimbri attacked the Romans with the utmost fury; but, being unaccustomed to bear the heats of Italy, they soon began to lose their strength, and were easily overcome. But they had put it out of their power to fly; for, that they might keep their ranks the better, they had, like true barbarians, tied themselves together with cords fastened to their belts, so that the Romans made a most terrible havock of them. The battle was therefore soon over, and the whole day employed only in the most terrible butchery. An hundred and twenty thousand were killed on the field of battle, and 60,000 taken prisoners. The victorious Romans then marched to the enemy's camp; where they had a new battle to fight with the women, whom they found more fierce than even their husbands had been. From their carts and waggons, which formed a kind of fortification, they discharged showers of darts and arrows on friends and foes without distinction. Then they first suffocated their children in their arms, and then they put an end to their own lives. The greatest part of them hanged themselves on trees. One was found hanging at a cart with two of her children at her heels. Many of the men, for want of trees and stakes, tied strings in running knots about their necks, and fastened them to the tails of their horses, and the horns and feet of their oxen, in order to strangle themselves that way; and thus the whole multitude was destroyed.

The country of the Cimbri, which, after this terrible catastrophe, was left a mere desert, was again peopled by the Scythians; who, being driven by Pompey out of that vast space between the Euxine and the Caspian sea, marched towards the north and west of Europe, subduing all the nations they met with in their way. They conquered Russia, Saxony, Westphalia, and other countries as far as Finland, Norway, and Sweden. It is pretended that Odin their leader traversed so many countries, and endeavoured to subdue them only with a view to excite the people against the Romans; and that the spirit of animosity which he had excited operated so powerfully after his death, that the northern nations combined to attack it, and never ceased their incursions till it was totally subverted.

CIMEX, or Bug, in zoology, a genus of insects belonging to the order of hemiptera. Linnaeus enumerates no fewer than 121 species. The lectularius, or common house-bug, is a well known insect. The methods of expelling them are various, as oil of turpentine

Cimolia
Cinchona.

pentine, the smoke of corn-mint, of narrow-leaved wild cress, of herb-robert, of the reddish agaric, of mustard, Guinea pepper, peas or turf, &c. See Bug.

CIMOLIA ALBA, the official name of the earth of which we now make tobacco-pipes. Its distinguishing characters are, that it is a dense, compact, heavy earth, of a dull white colour, and very close texture; it will not easily break between the fingers, and slightly stains the skin in handling. It adheres firmly to the tongue; melts very slowly in the mouth, and is not readily diffusible in water. It is found in many places. That of the Isle of Wight is much esteemed for its colour. Great plenty of it is found near Pole in Dorsetshire, and near Wedenbury in Staffordshire.

CIMOLIA Terra, in natural history, a name by which the ancients expressed a very valuable medicinal earth; but which latter ages have supposed to be no other than our tobacco-pipe clay and fuller's earth.

The *cimolia terra* of the ancients was found in several of the islands of the Archipelago; particularly in the island of Cimolus, from whence it had its name. It was used with great success in the erysipelas, inflammations, and the like, being applied by way of cataplasm to the part. They also used, as we do, what we call *cimolia*, or fuller's earth, for the cleansing of clothes. This earth of the ancients, though so long disregarded, and by many supposed to be lost, is yet very plentiful in Argentiére, (the ancient Cimolus,) Spanto, and many of those islands. It is a marl of a lax and crumbly texture, and a pure bright white colour, very soft to the touch. It adheres firmly to the tongue; and, if thrown into water, raises a little hissing and ebullition, and moulders to a fine powder. It makes a considerable effervescence with acids, and suffers no change of colour in the fire. These are the characters of what the ancients called simply *terra cimolia*; but besides this they had, from the same place, another earth which they called by the same general name, but distinguished by the epithet purple, *purpurejcentis*. This they described to be satiate, cold to the touch, of a mixed purple colour, and nearly as hard as a stone. And this was evidently the substance we call *steatites*, or the *soap-rock*, common in Cornwall, and also in the island of Argentiére, or Cimolus.

CIMON, the renowned Athenian general. See ATTICA, n° 95—103.

CINALOA, a province of Mexico in South America, abounding in corn, cattle, and cotton; and rendered extremely picturesque, by a number of beautiful cascades of clear water that fall down from the mountains. It lies on the eastern coast of the sea of California, and has a town of the same name, situated in N. Lat. 26°.

CINARA, in botany, the ARTICHOKE. See CYNARA.

CINCHONA, in botany, a genus of the monogynia order, belonging to the pentandria class of plants. There are two species. One of them, long remarkable for its bark, so much used in medicine under various names, is a native of some provinces of Peru in South America; the other, whose bark is but lately discovered to have the same medical virtues, is a native of Jamaica. The first was thought for a long

time to grow only in the province of Quito, on some hills near the city of Loxa; but it has since been found in other parts of that empire. It is a tree that seldom exceeds 18 feet in height, and is of a proportionally thickness. It grows in forests spontaneously among other trees; and is propagated by seeds which fall to the ground of themselves. Of the other species we have an account in the Phil. Trans. vol. 67. under Plate lxxiii. the name of *Cinchona Jamaicensis*. It grows on stony fig. 10. lands near the sea-shore on the north side of the island of Jamaica, and seldom exceeds 20 feet in height. The trunk is not thick in proportion, but hard, tough, and of a yellowish white colour on the inside. The branches and leaves are opposite; the leaves are of a rusty green, and the young buds of a bluish-green hue. It blossoms in November, and continues in flower till February, having on the same tree flowers and ripe pods. The flowers are of a dusky-yellow colour, and the pods black: when ripe they split in two, and are, with their flat brown seeds, in every respect similar to those of the first species, termed *cinchona officinalis*.

The bark of the cinchona officinalis hath now the highest reputation in the materia medica, and is justly looked upon as an almost universal medicine. It did not, however, acquire this great reputation all at once; nor, in all probability, when first discovered, did the cinchona merit those praises to which it is now so justly intitled. The reason of this is, that within these two centuries, as is observed by Dr Percival, the diseases of the European countries have assumed a new face. Formerly they were mostly of the inflammatory kind; and accordingly we find Dr Sydenham, a most experienced physician, treating almost all diseases in the manner proper for inflammatory ones. In these the Peruvian bark is pernicious. Its general characters are that of an astringent and corroborant; and these qualities necessarily augment inflammatory disorders. Now, to whatever cause it may be owing, diseases seem to arise mostly from a debility of the system, and hence the great efficacy of the bark in our times. At first it was only celebrated as a remedy for intermittent fevers; a long time after, it was discovered to be an antiseptic, to be efficacious in gangrenes, and mortifications, the scurvy, and all diseases in which there is a tendency to putrefaction. In the small-pox it is likewise of excellent use, where nature requires to be assisted in the expulsion of the variolous matter. The sanious and bloody matter in the variolous pustules also soon changes its appearance on the use of the bark; which needs only to be withheld if it is found to increase the difficulty of breathing. For the same reason it is exceedingly efficacious in foul old ulcers, very frequently correcting the sanies of them, and changing it into laudable pus. In nervous and putrid fevers, in sturuous affections also, particularly in ophthalmies of this kind, it has been found to be a remedy of great efficacy. The retrocession of the morbid matter in the measles is said to be powerfully prevented by the use of the bark; but where the lungs are affected, as they frequently are in this disease, the use of it is certainly to be avoided. Dr Percival informs us, that he had a patient who was seized with an intermittent while labouring under

a severe gonorrhœa. The bark was given him in large quantities ; and so far was it from lessening the discharge, that it evidently increased it, and lessened its virulence. The late Dr Whytt informs us, that, in 16 days, he swallowed near four ounces of the bark in substance, while labouring under a catarrhus cough, without feeling any bad effects from its astringent quality. In a tertian, attended with a violent cough and spitting, he prescribed the bark in the usual quantity, without its hurting the breast in the smallest degree. And he had repeated experience of its virtues in curing a hoarseness after the measles, when unattended with a fever and difficult respiration. In the whooping cough also, when given early, he found it one of the best remedies ; but here we must remark, that in some cases of the whooping cough where we have seen the bark administered, the disease was manifestly increased by it. Perhaps in these the medicine had been too long delayed. The bark has been successfully administered, in the quantity of a drachm every three hours, to a woman two days after her delivery, without lessening the lochia ; and it has been frequently given to others during their catamenia, without the least interruption of them. These and other facts are brought by Dr Percival, to prove that the prejudices against the use of the bark, which commonly take their rise from its known astringent quality, are altogether groundless.

As to the chemical analysis of this valuable medicine, the above mentioned author hath taken a great deal of pains to elucidate it. Other chemists had discovered that this, as well as many other vegetable substances, contains a mucilaginous and resinous part ; that the former is more soluble in water, and the latter in spirit of wine, &c. Dr Lewis particularly asserts, that the astringency of the Peruvian bark "resides wholly in its resin, which does not appear to be in any degree soluble in watery liquors." Also, that in making decoctions of the bark, the resin melts out in the first boilings ; and that the subsequent ones are transparent and bitter, without the least degree of turbidness or astringency. Both these assertions, however, Dr Percival hath shown to be mistakes. He digested a drachm of powdered bark 48 hours in two ounces of rectified spirit of wine. The clear tincture was then poured off, and fresh spirit, in the same quantity as before, added to the residuum. The digestion was repeated six times, until the menstruum acquired neither taste nor colour from the bark. The powder was then carefully dried and macerated without heat, in two several portions of spring-water, and communicated to each of them the property of striking a purple colour with green vitriol. Both the watery infusions were infpid ; from whence Dr Percival concludes, that rectified spirit of wine extracts all the biternefs, but not the astringency of the bark. To try the power of aqueous menstrua, he infused half an ounce of powdered bark in six ounces of cold spring-water for 48 hours, and boiled another half ounce for about 40 minutes in nine ounces of water. The cold infusion seemed to be at least as strong as the decoction ; and a considerable quantity of the resin appeared to have dissolved in the cold water ; for when boiled for some minutes over a quick fire, it grew turbid, and deposited a resinous precipitate. He now determined

to try whether it was possible to exhaust the bark of its resin by this treatment. Half an ounce of powdered bark was macerated for three days, in six ounces of water. The menstruum was then decanted off, and fresh water added in the same quantity as before. The effusion was repeated at equal intervals 30 times, till the water was infpid, colourless, and unalterable by the addition of green vitriol. The residuum also, when chewed in the mouth, had no sensible biternefs or astringency. Two drachms of this residuum, carefully dried by a very gentle heat, were infused in an ounce of rectified spirit of wine : in two days a tincture, of an orange colour and bitter taste was produced. This experiment was repeated with boiling water ; the bark was not exhausted till after the 25th coction ; and after all, gave a stronger tincture to spirit of wine than in the former case. These experiments shew how extremely difficult it is to exhaust the bark of its virtues ; neither is this only in appearance, but in reality ; for the same author informs us, that a quantity of bark, reduced by infusion and decoction to an infpid powder, was given in the dose of two drachms, to a person labouring under a quotidian ague, an hour or two before the coming on of the fit ; by which means the disease was changed into a tertian, and at last entirely removed. In short, Dr Percival hath clearly shown, that by one menstruum it is impossible to exhaust Peruvian bark entirely of its virtue ; but in order to determine with as much accuracy as possible the relation which different menstrua bear to it, he digested a drachm of the bark in three ounces of several different liquors. After seven days infusion, the clear part of each menstruum was carefully poured off, and the residuum evaporated to dryness. The weight lost by the bark in this experiment was thought to indicate the solvent power of each particular menstruum. The drachm infused in rectified spirit of wine, lost six grains ; in French brandy, eight grains and a quarter ; in Rhenish wine, nine grains ; in water, eight grains ; and in water and vinegar, the same quantity.

The doctor also tried a great number of other experiments with regard to the astringency and antiseptic qualities of the bark ; from whence he concludes, that its astringency is much less than has been commonly imagined ; and that in certain cases, particularly in bilious disorders, the addition of acids to the bark is necessary. Columbo-root he also thinks would be a useful addition in these diseases. From his experiments it would seem that a cold infusion of the bark is its best preparation ; but as that is very disagreeable to the taste, the addition of orange-peel and extract of liquorice will be found very convenient ; for these are found to cover the ill taste of this drug more effectually than any other.

The virtues of Peruvian bark were discovered by the Indians about the year 1500. A lake near a town in Peru was surrounded by these trees ; which were torn up by an earthquake, and falling into the adjacent water, they rendered it bitter. An Indian, urged by his thirst during a fever, under which he laboured, drank of this water, because no other could be had ; however, observing that he soon recovered, he related the case, and others were also cured. On

Cinchona
|
Cinnabar.

this enquiry was made, and to the trees it was found that the water owed its virtue; then it was soon discovered that the bark alone possessed the medicinal quality. In 1640, a Spanish soldier was quartered in an Indian's house, and being seized with an ague, his landlord, moved with compassion, told him of a cure, and with the same he cured his companions. At length the vice-queen, wife of the count de Cinchon, then vice-roy of Peru, was seized with an intermitting fever, this soldier cured her also; hence the name *cinchona* and *comitisse*. After this, father de Lugo brought a parcel of it to Rome, and from him it also received the name of *cort. card. de Lugo*. From Rome it was spread into France and England, and at length became general.

This bark is brought in pieces of different sizes, some rolled up in short thick quills, and others flat; the outside is brownish, and generally hath a whitish moss spread on it; the inside is of a yellowish, reddish, or rusty iron colour. The best sort is bitter, resinous, breaks close and smooth, is friable betwixt the teeth, pulverises easily, when powdered is of a cinnamon colour, but rather paler; and, according to the opinion of some, as the truest test of its goodness, it hath a musty kind of smell, and at the same time so much of the aromatic, as not to be disagreeable. The inferior kinds, when broken, appear woody, and in chewing separate into fibres. That which is called female bark, is redder in the inside; it is also thicker; and on the outside more white and smooth; is weaker to the smell and taste than the above; and, in medical virtue, greatly inferior.—The bark of the *cinchona jamaicensis* is found to yield its virtues much better to watery menstrua than the officinalis; and, as far as has yet been tried, seems not inferior in efficacy.

CININNATUS, the Roman dictator, was taken from the plough, to be advanced to the dignity of consul; in which office he restored public tranquillity, and then returned to his rural employments. Being called forth a second time to be dictator, he conquered the enemies of Rome, and, refusing all rewards, retired again to his farm, after he had been dictator only 16 days. The same circumstance appeared once more in the 80th year of his age. He died 376 years before Christ.

CINCTURE, in architecture, a ring, list, or orlo, at the top and bottom of the shaft of a column, separating the shaft at one end from the base, and at the other from the capital.

CINERITIOUS, an appellation given to different substances, on account of their resembling ashes either in colour or consistence; hence it is that the cortical part of the brain has sometimes got this epithet.

CINNABAR, in natural history, is either native or factitious.

The *native* cinnabar is an ore of quicksilver, moderately compact, very heavy, and of an elegant striated red colour.

Factitious cinnabar is a mixture of mercury and sulphur sublimed, and thus reduced into a fine red glebe. The best is of a high colour, and full of fibres like needles. See CHEMISTRY, n° 474, and PHARMACY, n° 753.—793.

The chief use of cinnabar is for painting. Although

the body is composed of sulphur, which is of a light colour, and mercury which is white as silver, it is nevertheless of an exceeding strong red colour. Lumps of it are of a deep brown red without brilliancy; but when the too great intensity of its colour is diminished by bruising and dividing it into small parts, (which is a method generally used to lessen the intensity of all colours), the red of the cinnabar becomes more and more exalted, flame-coloured, and exceedingly vivid and brilliant: in this state it is called vermilion.

Cinnabar is often employed as an internal medicine. Hoffman greatly recommends it as a sedative and antispasmodic; and Stahl makes it an ingredient in his *temperant powder*. Other intelligent physicians deny that cinnabar taken internally has any medicinal quality. Their opinion is grounded on the insolubility of this substance in any menstruum. This question concerning its internal utility cannot be decided without further researches and experiments; but cinnabar is certainly used with success to procure a mercurial fumigation, when that method of cure is proper in venereal diseases. For this purpose it is burnt in an open fire on red-hot coals, by which the mercury is disengaged and forms vapours, which, being applied to the body of the diseased person, penetrate through the pores of the skin, and produce effects similar to those of mercury administered by friction.

CINNAMON-TREE, in botany. See LAURUS.

CINNAMON-WATER, is made by distilling the bark first infused in spirit of wine, brandy, or white-wine.

Gloves CINNAMON, is the bark of a tree growing in Brazil, which is often substituted for real cloves.

White CINNAMON, called also *Winter's bark*, is the bark of a tree frequent in the isle of St Domingo, Guadalupe, &c. of a sharp biting taste like pepper. Some use it instead of nutmeg; and in medicine it is esteemed a stomachic and antiscorbutic.

CINNAMUS, a Greek historian, wrote a history of the eastern empire, during the reigns of John and Manuel Commenes, from 1118 to 1143. His style is reckoned the best of the modern Greek authors. He died after 1183.

CINQUEFOIL, in botany. See POTENTILLA.

CINQUE-PORTS, five havens that lie on the east part of England, towards France; thus called, by way of eminence on account of their superior importance, as having been thought by our kings to merit a particular regard, for their preservation against invasion. Hence they have a particular policy, and are governed by a keeper, with the title of *Lord-warden of the cinque-ports*.

Cambden tells us, that William the Conqueror first appointed a warden of the cinque-ports; but king John first granted them their privileges; and that upon condition they should provide eighty ships at their own charge for forty days, as often as the king should have occasion in the wars: he being then straitened for a navy to recover Normandy.

The five ports are Hastings, Romney, Hythe, Dover, and Sandwich.—Thorn tells us, that Hastings provided 21 vessels; and in each vessel 21 men. To this port belong Seaford, Pevensey, Hedney, Winchelsea, Rye, Hamne, Wakebourn, Creneth, and Fordcliffe.—Romney provided five ships, and in each 24 men.

Cipher.

To this belong Bromhal, Lyde, Ofwarstone, Dange-mares, and Romenhal.—Hythe furnished five ships, and in each 21 seamen. To this belongs Westmeath.—Dover the same number as Haflings. To this belong Folkton, Feverham, and Marge.—*Laffly*, Sand-wich furnished the same with Hythe. To this belong Fordiwic, Reculver, Serre, and Deal.

The privileges granted to them in consequence of these services were very great. Amongst others they were each of them to send two barons to represent them in parliament; their deputies were to bear the canopy over the king's head at the time of his coronation, and to dine at the uppermost table in the great hall on his right hand; to be exempted from subsidies and other aids; their heirs to be free from personal wardship, notwithstanding any tenure; to be impleaded in their own towns, and not elsewhere; not to be liable to tolls, &c.

CINTRA, a cape and mountain of Portugal, in the province of Estremadura, usually called the *Rock of Lisbon*. It lies on the north side of the entrance of the river Tajo; and there is a town of the same name situated thereon. W. Long. 10. 15. N. Lat. 59. 0.

CINUS, or CYNUS, a famous civilian of Pistoia in the 14th century. His commentary on the Code was finished in 1313; he also wrote on some parts of the digest. He was no less famous for his Italian poems; and is ranked among those who first gave grace to the Tuscan lyric poetry.

CINYRA, in the Jewish antiquities, a musical instrument. This, and the Hebrew *cinnor*, which is generally translated *cithara*, *lyra*, or *psalterium*, are the same. It was made of wood, and was played on the temple of Jerusalem. Josephus says that the *cinyra* of the temple had ten strings, and that it was touched with a bow. In another place he says that Solomon made a great number of them with a precious kind of metal called *electrum*; wherein he contradicts the scripture, which inform us that Solomon's *cinnors* were made of wood.

CION, or CYON, in gardening, a young shoot, sprout, or sprig, put forth by a tree. Grafting is performed by the application of the cion of one plant upon the stock of another. To produce a stock of cions for grafting, planting, &c. the gardeners sometimes cut off the bodies of trees a little above the ground, and only leave a stump or root standing; the redundant sap will not fail next spring to put forth a great number of shoots. In dressing dwarf-trees, a great many cions are to be cut off.

CIOTAT, a sea-port town of Provence in France; famous for Muscadine wine. It is seated on the bay of Laquea, between Marseilles and Toulon; and the harbour is defended by a strong fort. E. Long. 5. 30. N. Lat. 43. 10.

CIPHER, or CYPHER, one of the Arabic characters or figures used in computation, formed thus, 0. See ARITHMETIC.

CIPHER is also a kind of enigmatic character, composed of several letters interwoven, which are generally the initial letters of the persons names for whom the ciphers are intended. These are frequently used on seals, coaches, and other moveables.—Anciently,

merchants and tradesmen were not allowed to bear arms: in lieu thereof, they bore their ciphers, or the initial letters of their names, artfully interwove about a cross; of which we have divers instances on tombs, &c. See DEVISE.

CIPHER, denotes likewise certain secret characters disguised and varied, used in writing letters that contain some secret, not to be understood but by those between whom the cipher is agreed on.

De la Guilletiere, in his *Lacedæmon ancient and modern*, endeavours to make the ancient Spartans the inventors of the art of writing in cipher. Their scytala, according to him, was the first sketch of this mysterious art: these scytalæ were two rollers of wood, of equal length and thickness; one of them kept by the ephori; the other by the general of the army sent on any expedition against the enemy. Whensoever those magistrates would send any secret orders to the general, they took a slip of parchment, and rolled it very justly about the scytala which they had reserved; and in this state wrote their intentions, which appeared perfect and consistent while the parchment continued on the roller: when taken off, the writing was maimed, and without connection; but was easily retrieved by the general, upon his applying it to his scytala.

Polybius says, that Æneas Tactitus, 2000 years ago collected together 20 different manners of writing lo as not to be understood by any but those in the secret; part whereof were invented by himself, and part used before his time.—Trithemius, Cap. Porta, Vigenere, and P. Nicéron, have wrote expressly on the subject of ciphers.

As the writing in cipher is become an art; so is the reading, or unravelling thereof, called *deciphering*.—The rules of deciphering are different in different languages. By observing the following, you will soon make out any common cipher wrote in English.

1. Observe the letters or characters that most frequently occur; and set them down for the six vowels, including *y*; and of these the most frequent will generally be *e*, and the least frequent *u*.

2. The vowels that most frequently come together are *ea* and *ou*.

3. The consonant most common at the ends of words is *s*, and the next frequent *r* and *t*.

4. When two similar characters come together, they are most likely to be the consonants *f*, *l*, or *s*, or the vowels *e* or *o*.

5. The letter that precedes or follows two similar characters is either a vowel, or *l*, *m*, *n*, or *r*.

6. In deciphering, begin with the words that consist of a single letter, which will be either *a*, *I*, *e*, or *o*.

7. Then take the words of two letters, one of which will be a vowel. Of these words the most frequent are, *an*, *to*, *be*, *by*, *of*, *on*, *or*, *no*, *so*, *ai*, *at*, *if*, *in*, *is*, *it*, *he*, *me*, *my*, *us*, *we*, *am*.

8. In words of three letters there are most commonly two consonants. Of these words the most frequent are, *the*, *and*, *not*, *but*, *yet*, *for*, *tho'*, *how*, *why*, *all*, *you*, *she*, *his*, *her*, *our*, *who*, *may*, *can*, *did*, *was*, *are*, *has*, *had*, *let*, *one*, *two*, *six*, *ten*, &c.*

II T 2

9. The

* Some of these, or those of two letters, will be found in every sentence.

Cipher.

Cipher.

9. The most common words of four letters are, *this, that, then, thus, with, when, from, here, some, most, none, they, them, whom, mine, your, self, must, will, have, been, were, four, five, nine, &c.*

10. The most usual words of five letters are, *these, those, which, were, while, since, their, shall, might, could, would, ought, three, seven, eight, &c.*

11. Words of two or more syllables frequently begin with double consonants, or with a preposition; that is, a vowel joined with one or more consonants. The most common double consonants are *bl, br, dr, fl, fr, gl, gr, ph, pl, pr, sh, st, th, tr, wh, wr, &c.* and the most common propositions are *con, con, de, dis, ex, in, in, int, mis, par, pre, pro, re, sub, sup, un, &c.*

12. The double consonants most frequent at the end of long words are, *ck, ld, lf, mn, nd, ng, rl, rm, rn, rp, rt, sn, st, xt, &c.* and the most common terminations are *cd, en, er, et, eng, ly, son, sion, tion, able, ence, ent, ment, full, less, ness, &c.*

On Plate LXXIX. fig. 7. is given an example of a cipher wrote in arbitrary characters as is commonly practised. It will be easily deciphered by observing the rules: but when the characters are all placed close together, as in the example fig. 8. and as they always should be, the deciphering is much more difficult.

To decipher a writing of this sort you must first look for those characters that most frequently occur, and set them down for vowels as before. Then observe the similar characters that come together; but you must remember that two such characters may here belong to two words. You are next to remember the combinations of two or three characters that are most frequent; which will be some of the words in the seventh and eighth of the foregoing rules; and by observing the other rules, you will infallibly discover, with time and attention, any cipher wrote on these principles.

When the words are wrote all close together, if the key to the cipher were to be changed every word, according to a regular method agreed on between the parties, as might be done by either of the methods mentioned in N^o II. below, with very little additional trouble, the writing would then be extremely difficult to decipher. The longer any letter wrote in cipher is, the more easy it is to decipher, as then the repetitions of the characters and combinations are the more frequent.

The following are the contents of the two foregoing ciphers; in which we have inverted the order of the words and letters, that they who are desirous of trying their talent at deciphering, may not, inadvertently, read the explanation before the cipher.

enil eno ton dna shnmo elolw eerht, suoidisrep dna leure o. noituae & enedupr fo klat llw uoy : on, rotiait, tcelgen & enereffidni si ti. yltrohs rettelt a em dnes ot snaem emof dnif rehtie, trach eht morf semoc ti talit ees em tel &, erom ecaf ym ees ot erad reven ro.

Contrivances for communicating intelligence by CIPHER.

Cipher.

I. By means of a pack of cards. The parties must previously agree in what manner the cards shall be first placed, and then how they shall be shuffled. Thus suppose the cards are to be first placed in the order as hereafter follows, and then shuffled by taking off 3 from the top, putting the next 2 over them, and the following 3 under them*, and so alternately. Therefore the party who sends the cipher first writes the contents of it on a separate paper, and then copies the first 32 letters on the cards, by writing one letter on every card; he then shuffles them, in the manner described, and writes the second 32 letters: he shuffles them a second time, and writes the third 32 letters, and so of the rest. An example will make this plain. Suppose the letter to be as follows:

I am in full march to relieve you; within three days I shall be with you. If the enemy in the mean time should make an assault, remember what you owe to your country, to your family and yourself. Live with honour, or die with glory.

Order of the cards before the 1st shuffle.

King clubs	i n a t h
Knave diamonds	n e u r o

The person that receives these cards first places them in the order agreed on, and transcribes the first letter on every card. He then shuffles them, according to order, and transcribes the second letter on each card. He shuffles them a second time and transcribes the third letters; and so of the rest.

If the cards were to be shuffled the second time by threes and fours, the third time by twos and fours, &c.

* By shuffling the cards in this manner, there will remain only 2 to put under at last.

Cipher.

it would make the cipher still more difficult to discover : though as all ciphers depend on the combination of letters, there are scarce any that may not be deciphered with time and pains ; as we shall flow further on. Those ciphers are the best, that are by their nature most free from suspicion of being ciphers ; as for example, if the letters were here wrote with one of the sympathetic inks, described in the fourth volume of this work, the cards might then pass for a common pack.

II. *By a dial.* On a piece of square pasteboard ABCD, fig. 3. 4. draw the circle EFGH, and divide it into 26 equal parts, in each of which must be wrote one of the letters of the alphabet.

On the inside of this there must be another circle of pasteboard, ILMN, moveable round the centre O, and the extremity of this must be divided into the same number of equal parts as the other. On this also must be wrote the letters of the alphabet, which, however, need not be disposed in the same order. The person with whom you correspond must have a similar dial, and at the beginning of your letter you must put any two letters that answer to each other when you have fixed the dial.

Exam. Suppose you would write as follows : " If you will come over to us, you shall have a pension, and you may still make a sham opposition." You begin with the letters *Ma*, which show how the dial is fixed : then for *If you*, you write *un juc*, and so for the rest, as you will see at fig. 6.

The same intention may be answered by a ruler, the upper part of which is fixed and the lower part made to slide ; but in this case the upper part must contain two alphabets in succession, that some letter of that part may constantly correspond to one in the lower part. The divisions standing directly over each other in a straight line will be much more obvious than in the circumference of a circle. Or two straight pieces of pasteboard regularly divided, the one containing a single and the other a double alphabet, would answer exactly the same purpose. In this case a blank space may be left at each end of the single alphabet, and one or two weights being placed on both the pieces will keep them steady.

III. *The corresponding spaces.* Take two pieces of pasteboard or stiff paper, through which you must cut long squares, at different distances, as you will see in the following example. One of these pieces you keep yourself, and the other you give to your correspondent. When you would send him any secret intelligence, you lay the pasteboard upon a paper of the same size, and in the spaces cut out, you write what you would have understood by him only, and then fill up the intermediate spaces with somewhat that makes with those words a different sense.

[I shall be] much obliged to you, as reading [alone] engages my attention [at] present, if you will lend me any one of the [eight] volumes of the Spectator. I hope you will excuse [this] freedom, but for a winter's [evening] I [don't] know a better entertainment. If I [fail] to return it soon, never trust me for the time [to come].

Cipher

CIPPUS.

A paper of this sort may be placed four different ways, either by putting the bottom at the top, or by turning it over, and by those means the superfluous words may be the more easily adapted to the sense of the others.

This is a very eligible cipher, as it is free from suspicion, but it will do only for short messages : for if the spaces be frequent, it will be very difficult to make the concealed and obvious meanings agree together : and if the sense be not clear, the writing will be liable to suspicion.

IV. *The musical cipher.* The construction of this cipher, is similar to that of N^o II. The circle EFGH (fig. 3.) is to be divided into twenty-six equal parts, in each part there must be wrote one of the letters of the alphabet : and on the anterior circle ILMN, moveable round the center O, there is to be the same number of divisions : the circumference of the inner circle must be ruled in the manner of a music paper ; and in each division there is to be placed a note, differing either in figure or position. Lastly, within the musical lines place the three keys, and on the outer circle, the figures that are commonly used to denote the time.

Then provide yourself with a ruled paper, and place one of the keys, as suppose that of *g re sol*, against the time two-fourths at the beginning of the paper, which will inform your correspondent how to fix his circle. You then copy the notes that answer to the several letters of the words you intend to write, in the manner expressed at fig. 5.

A cypher of this sort may be made more difficult to discover by frequently changing the key, and that will not in the least embarrass the reader. You may likewise add the mark *#* or *b* to the note that begins a word, which will make it more easy to read, and at the same time give the music a more natural aspect. This cipher is preferable to that of N^o II. above, as it may be inclosed in a letter about common affairs, and pass unsuspected.

CIPPUS, in antiquity, a low column, with an inscription, erected on the high roads, or other places, to shew the way to travellers ; to serve as a boundary ; to mark the grave of a deceased person, &c.

CIR (St), a village of France, two miles from Versailles, remarkable for a nunnery founded here by Lewis XIV. The nuns are obliged to take care of the education of 250 girls, who must prove their families to have been noble from the 4th generation on the father's side. They cannot enter before 7, nor after 12 years of age : and they continue there till they are 20 years and 3 months old. The house is a most magnificent structure.

CIRCÆA, ENCHANTER'S NIGHT-SHADE, a genus of the monogynia order belonging to the diandria class of plants. There are two species, one of which is a native of Britain, and the other of Germany. They are low herbaceous plants with white flowers, and possessed of no remarkable property.

CIRCASSIA, a large country of Asia, lying between the rivers Don and Wolga ; bounded on the north by Russia, on the east by Astrachan and the Caspian sea,

on

on the south by Georgia and Dagistan, and on the west by the sea of Zabach. It is full of mountains and forests, and has no other city but Terky, which is seated on the Caspian sea. It is a kind of republic; for the people put themselves under the protection of Persia, Russia, and the Turks: however, the last are in possession of Terky, the capital town. They are Tartars of a middle stature, well-set, with coarse black hair and broad flat faces. They wear a vest of coarse grey cloth, and over it a sheep's skin, which they turn to the side from which the wind or rain comes. They have boots of horse leather, and wear on their heads round bonnets of coarse felt or black cloth. The women pass among the Turks for very great beauties, their complexion being extremely fine. The men are not jealous; for they allow their wives all imaginable liberties. These, in the summer, wear nothing but a shift open down to the navel; but in the winter they have furred gowns, like the Russians. They are very fond of necklaces, which consist of strings of pearls, or coloured glass. It is not a little surprising that the men should be so ugly, and the women so extremely handsome. Their religion is a mixture of Christianity and Mahometanism; and, like the Jews, they marry their brother's wives, if they have no children. The men are good horsemen, and subsist chiefly by hunting and robbing, though some are addicted to husbandry. In winter they live in forty huts, and in the summer in tents. Their female children are generally bought by the Turks and Persians, who bring them up for their seragios.

CIRCE, in fabulous history, a famous sorceress, poisoned her husband, king of the Sarmatæ; for which being banished, she came into Italy, where she changed Scylla into a sea-monster; the entertained Ulysses, who was cast away on the coast near her house, but metamorphosed his companions into different sorts of beasts.

CIRCENSIAN GAMES, a general term, under which was comprehended all combats exhibited in the Roman circus, in imitation of the Olympic games in Greece. Most of the feasts of the Romans were accompanied with Circensian games; and the magistrates, and other officers of the republic, frequently presented the people with them, in order to procure their favour. The grand games were held five days, commencing on the 15th of September. There were six kinds of games exhibited: the first was wrestling, and fighting with swords, with staves, and with pikes; the second was racing; the third leaping; the fourth, quoits, arrows, and cestus; all which were on foot: the fifth was horse-courting; the sixth courses of chariots.

CIRCLE, in geometry, a plane figure comprehended by a single curve line, called its circumference, to which right lines drawn from a point in the middle, called the centre, are equal to each other. See GEOMETRY.

Circles of the Sphere, are such as cut the mundane sphere, and have their periphery either on its moveable surface, or in another immoveable, conterminous, and equidistant surface. See SPHERE. Hence arise two kinds of circles, *moveable* and *immoveable*. The first, those whose peripheries are in the moveable surface, and which therefore revolve with its diurnal mo-

tion; as, the *meridians*, &c. The latter having their periphery in the immoveable surface, do not revolve; as the *ecciptic*, *equator*, and its *parallels*, &c. See GEOGRAPHY.

CIRCLES of Altitude, otherwise called *almucantars*, are circles parallel to the horizon, having their common pole in the zenith, and still diminishing as they approach the zenith. See ALMUCANTAR.

Diurnal CIRCLES, are immoveable circles, supposed to be described by the seven stars, and other points of the heavens, in their diurnal rotation round the earth; or rather, in the rotation of the earth round its axis. The *diurnal circles* are all unequal: the equator is the biggest.

Horary CIRCLES, in dialing, are the lines which shew the hours on dials; though these be not drawn circular, but nearly straight. See DIALING.

CIRCLES of Latitude, or *Secondaries of the Ecciptic*, are great circles parallel to the plane of the ecciptic, passing through the poles thereof, and through every star and planet. They are so called, because they serve to measure the latitude of the stars, which is nothing but an arch of one of these circles intercepted between the star and the ecciptic. See LATITUDE.

CIRCLES of Longitude, are several lesser circles, parallel to the ecciptic; still diminishing, in proportion as they recede from it. On the arches of these circles, the longitude of the stars is reckoned.

CIRCLE of perpetual Apparition, one of the lesser circles, parallel to the equator; described by any point of the sphere touching the northern point of the horizon; and carried about with the diurnal motion. All the stars included within this circle never set, but are ever visible above the horizon.

CIRCLE of perpetual Occultation, is another circle at a like distance from the equator; and contains all those stars which never appear in our hemisphere. The stars situate between these circles, alternately rise and set at certain times.

Polar CIRCLES, are immoveable circles, parallel to the equator, and at a distance from the poles equal to the greatest declination of the ecciptic. That next the northern pole is called the ARCTIC; and that next to the southern one the ANTARCTIC.

Fairy CIRCLE. See FAIRY-CIRCLE.

CIRCLE, in logic, or Logical CIRCLE, is when the same terms are proved in *orbem* by the same terms; and the parts of the syllogism alternately by each other, both directly and indirectly.

CIRCLES of the Empire, such provinces and principalities of the German empire as have a right to be present at diets. Maximilian I. divided the empire into fix, and some years after into ten circles. This last division was confirmed by Charles V. The circles, as they stand in the Imperial Matricula, are as follow: Austria, Burgundy, the Lower Rhine, Bavaria, Upper Saxony, Transania, Swabia, Upper Rhine, Westphalia, and the Lower Saxony.

CIRCUMCELLIONES, a species of fanatics, so called because they were continually rambling round the houses in the country. They took their rise among the donatists, in the reign of the emperor Constantine. It is incredible what ravages and cruelties these vagabonds committed in Africa through a long series of years.

years. They were illiterate, savage peasants, who understood only the Punic language. Intoxicated with a barbarous zeal, they renounced agriculture, professed continence, and assumed the title of "Vindicators of justice, and Protectors of the oppressed." To accomplish their mission, they enfranchised slaves, scourged the roads, forced masters to alight from their chariots, and run before their slaves, whom they obliged to mount in their place; and discharged debtors, killing the creditors if they refused to cancel the bonds. But the chief objects of their cruelty were the catholics, and especially those who had renounced donatism. At first they used no swords, because God had forbid the use of one to Peter; but they were armed with clubs, which they called the *clubs of Israel*; and which they handled in such a manner as to break a man's bones without killing him immediately, so that he languished a long time and then died. When they took away a man's life at once, they looked upon it as a favour. They became less scrupulous afterwards, and made use of all sorts of arms. Their shout was *Fraïse be to God*. These words in their mouths were the signal of slaughter, more terrible than the roaring of a lion. They had invented an unheard-of punishment; which was, to cover with lime diluted with vinegar, the eyes of those unhappy wretches whom they had crushed with blows, and covered with wounds, and to abandon them in that condition. Never was a stronger proof what horrors superstition can beget in minds destitute of knowledge and humanity. These brutes who had made a vow of chastity, gave themselves up to wine and all sorts of impurities, running about with women and young girls as drunk as themselves, whom they called *sacred virgins*, and who often carried proofs of their incontinence. Their chiefs took the name of *Chiefs of the Saints*. After having glutted themselves with blood, they turned their rage upon themselves, and sought death with the same fury with which they gave it to others. Some scrambled up to the tops of rocks, and cast themselves down headlong in multitudes; others burned themselves, or threw themselves into the sea. Those who proposed to acquire the title of martyrs, published it long before; upon which they were feasted and fattened like oxen for the slaughter; after these preparations they set out to be destroyed. Sometimes they gave money to those whom they met, and threatened to murder them if they did not make them martyrs. Theodorat gives an account of a stout young man, who meeting with a troop of these fanatics, consented to kill them, provided he might bind them first; and having by this means put it out of their power to defend themselves, whipped them as long as he was able, and then left them tied in that manner. Their bishops pretended to blame them, but in reality, made use of them to intimidate such as might be tempted to forsake their sect; they even honoured them as saints. They were not, however, able to govern those furious monsters; and more than once found themselves under a necessity of abandoning them, and even of imploring the assistance of the secular power against them. The counts Urfacius and Taurinus were employed to quell them; they destroyed a great number of them, of whom the

donatists made as many martyrs. Urfacius, who was a good catholic and a religious man, having lost his life in an engagement with the barbarians, the donatists did not fail to triumph in his death, as an effect of the vengeance of heaven. Africa was the theatre of these bloody scenes during a great part of Constantine's life.

CIRCUIT, in law, signifies a longer course of proceedings than is needful to recover the thing sued for.

CIRCUIT, also signifies the journey or progress, which the judges take twice every year, through the several counties of England and Wales, to hold courts and administer justice, where recourse cannot be had to the king's courts at Westminster: hence England is divided into six circuits, *viz.* the Home circuit; Norfolk circuit; Midland circuit; Oxford circuit; Western circuit, and Northern circuit. In Wales there are but two circuits, North and South Wales: two judges are assigned by the king's commission to every circuit.

In Scotland, the judges of the supreme criminal court, or court of judicatory, are divided into three separate courts, consisting of two judges each; and the kingdom into as many districts. In certain boroughs of every district, each of these courts by rotation are obliged to hold two courts in the year, in spring and autumn; which are called *circuit-courts*.

CIRCULAR, in a general sense, any thing that is described, or moved in a round, as the circumference of a circle, or surface of a globe.

CIRCULAR Numbers, called also *spherical ones*, according to some, are such whose powers terminate in the roots themselves. Thus, for instance, 5 and 6, all whose powers do end in 5 and 6, as the square of 5 is 25; the square of 6 is 36, &c.

CIRCULAR Sailing, is the method of sailing by the arch of a great circle. See **NAVIGATION**.

CIRCULATION, the act of moving round, or in a circle; thus we say, the circulation of the blood, &c.

CIRCULATION of the Blood, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart into all parts of the body, by the arteries, from whence it is brought back to the heart again by the veins. See **ANATOMY**, n° 387, 388, 389.

In a fetus, the apparatus for the circulation of the blood is somewhat different from that in adults. The septum, which separates the two auricles of the heart, is pierced through with an aperture, called the *foramen ovale*; and the trunk of the *pulmonary artery*, a little after it has left the heart, sends out a tube into the descending aorta, called the communicating canal. The fetus being born, the foramen ovale closes by degrees, and the canal of communication dries up, and becomes a simple ligament.

As to the velocity of the circulating blood, and the time wherein the circulation is completed, several computations have been made. By Dr Keil's account, the blood is driven out of the heart into the aorta with a velocity which would carry it twenty-five feet in a minute: but this velocity is continually abated in the progress of the blood, in the numerous sections or branches of the arteries, so that before it arrive at the

the extremities of the body, its motion is greatly diminished. The space of time wherein the whole mass of blood ordinarily circulates, is variously determined. Some state it thus: Supposing the heart to make two thousand pulses in an hour, and that at every pulse there is expelled an ounce of blood; is not ordinarily computed to exceed twenty-four pounds, it must be circulated seven or eight times over in the space of an hour.

The curious, in microscopic observations, have found an easy method of seeing the circulation of the blood in the bodies of animals: for these inquiries it is necessary to chuse such animals as are small, and easily manageable, and which are either wholly or in part transparent. The observations made by this means are preferable to any others we can have recourse to; since, in dissections, the animal is in a state of pain, or dying; whereas in animals small enough to be thus viewed, all is left in its usual course, and we see what nature does in her own undisturbed method. In these creatures also, after viewing, as long as we please, the natural state and current of the blood, we may, by pressure, and several other ways, impede its course; and by putting various mixtures into the creature's water, induce a morbid state, and finally see the creature die, either by means of this or by any other method; and we may thus accurately observe all the changes it undergoes, and see what occasions the trembling pulse, &c. of dying people.

The current of the blood in small animals, that is, its passing on through the vessels, either to or from the heart is very easily seen by the microscope; but its circulation, that is, its running to the extremities of the parts, and thence returning, is more difficult; because the vessels where this should be seen are so extremely minute, as not easily to come under observation. The larger arteries are easily distinguished from the veins by the motion of the blood through them, which, in the veins is always smooth and regular; but in the arteries by several propulsions after the manner of pulsation. But this difference is not to be found in the more minute vessels, in all which, as well arteries as veins, the motion of the blood is even and regular.

The transparent membrane, or web between the toes of a frog's hinder foot, is a very proper object to observe the circulation of the blood in. The tails, or fins of fishes, are also very fine objects, and when the fish is very small, these are manageable, and afford a view of a great number of veins and arteries, with a very quick and beautiful succession of blood through them. The tail of a flounder may be very conveniently placed before the double microscope on a plate of glass, and its body being supported by something of equal height the fish will lie still, and the circulation may be seen very agreeably. In the minutest vessels thus examined, the blood always appears pale or colourless, but in the large ones it is manifestly red. The arteries usually branch out extremely before they join the veins to carry the blood back to the heart; but this is not always the case; for Mr Leuwenhoeck has observed, that on each side of the little gillfish which give a stiffness to the tail of a flounder, there may be seen a very open communi-

cation of the veins and arteries; the blood running towards the extremities through arteries, and returning back again through veins, which were evidently a continuation of those arteries, and of the same diameter with them. The whole fish on the tail of which this examination was made, was not more than half an inch in length; it is easy to conceive, therefore, how small the tail must be; and yet in it there were 68 vessels which carried and returned the blood; and yet these vessels were far from being the most minute of all. How inconceivably numerous then must the *circulations* in the whole human body be? Mr Leuwenhoeck is of opinion, that a thousand different circulations are continually carried on in every part of a man's body in the breadth of a finger nail.

The tail of a newt or water-lizard affords also a very entertaining prospect of the circulation of the blood through almost numberless small vessels; but no object shews it so agreeably as one of these animals while so young as not to be above an inch long; for then the whole body is so very transparent, that the circulation may be seen in every part of it, as well as in the tail; and, in these objects, nothing is more beautiful than the course of the blood into the toes and back again, where it may be traced all the way with great ease. Near the head there are also found three small fins which afford a very delightful prospect: these are all divided like the leaves of polyphy; and in every one of the branches of these, the blood may be very accurately traced, running to the end through the artery, and there returning back again by a vein of the same size, and laid in the same direction; and as the vessels are very numerous and large in this part, and the third or fourth magnifier may be used, there are sometimes seen 30 or 40 channels of running blood at once; and this the more as the globules of blood in the newt are large, and are fewer in number, in proportion to the quantity of serum, than in any other animal; and their figure, as they are protruded through the vessels, changes in a very surprising manner. The impetus occasioning the circulation, is great enough in some animals to raise the blood six, seven, or eight feet high from the blood-vessel it springs out at; which, however, is far exceeded by that of the sap of a vine in bleeding time, which will sometimes rise forty feet high.

CIRCULATION of the Sap of Plants. See PLANTS, and SAP.

CIRCULATION of the Spirits, or Nervous Fluid. See ANATOMY, n° 400, h; and NERVOUS FLUID.

CIRCULATION, in chemistry, is an operation whereby the same vapour, raised by fire, falls back, to be returned and distilled several times.

CIRCULATION of Money. See COMMERCE, and MONEY.

Subterranean CIRCULATION. See SPRINGS.

CIRCULUS, in chemistry, an iron instrument in form of a ring, which being heated red hot, and applied to the necks of retorts and other glass vessels till they grow hot, a few drops of cold water thrown upon them, or a cold blast, will make the necks fly regularly and evenly off.

Another method of doing this, is to tie a thread, first

Circumam-
bient

Circumfer-
rentor.

first dipt in oil of turpentine, round the place where you would have it break; and then setting fire to the thread, and afterwards sprinkling the place with cold water, the glass will crack exactly where the thread was tied.

CIRCUMAMBIENT, an appellation given to a thing that surrounds another on all sides; chiefly used in speaking of the air.

CIRCUMCELLIONES. See **CIRCONCELLIONES**.

CIRCUMCISION, the act of cutting off the prepuce; a ceremony in the Jewish and Mahometan religions, wherein they cut off the foreskin of their males, who are to profess the one or the other law.

Circumcision commenced in the time of Abraham; and was, as it were, the seal of a covenant stipulated between God and him. It was in the year of the world 2178, that Abraham, by divine appointment, circumcised himself, and all the males of his family; from which time it became an hereditary practice among his descendants.

The ceremony, however, was not confined to the Jews: Herodotus and Philo Judeus observe, that it obtained also among the Egyptians and Ethiopians. Herodotus says, that the custom was very ancient among each people; so that there was no determining which of them borrowed it from the other. The same historian relates, that the inhabitants of Colchis also used circumcision; whence he concludes, that they were originally Egyptians. He adds, that the Phœnicians and Syrians were likewise circumcised; but that they borrowed the practice from the Egyptians. And lastly, that a little before the time when he wrote, circumcision had passed from Colchis, to the people inhabiting near Thermoodon and Parthenius.

Marham is of opinion, that the Hebrews borrowed circumcision from the Egyptians; and that God was not the first author thereof; citing Diodorus Siculus, and Herodotus, as evidences on his side. This latter proposition seems directly contrary to the testimony of Moses, who assures, Gen. xvii. that Abraham, tho' 99 years of age, was not circumcised till he had the express command of God for it. But as to the former position of Marham, it will admit of more debate. The arguments on both sides may be seen in one view in *Spencer de Legibus Hebræorum*, l. 2. c. 4.

Be this as it will, it is certain the practice of circumcision among the Hebrews differed very considerably from that of the Egyptians. Among the first it was a ceremony of religion, and was performed on the eighth day after the birth of the child. Among the latter, a point of mere decency and cleanliness; and, as some will have it, of physical necessity; and was not performed till the 13th year, and then on girls as well as boys.

Among the Jews the time for performing this rite was the eighth day, that is, six full days, after the child was born: the law of Moses ordained nothing with respect to the person by whom, the instrument with which, or the manner how, the ceremony was to be performed; the instrument was generally a knife of stone. The child is usually circumcised at home, where the

father, or godfather, holds him in his arms, while the operator takes hold of the prepuce with one hand, and with the other cuts it off; a third person holds a porringer, with sand in it, to catch the blood; then the operator applies his mouth to the part, and, having sucked the blood, spits it into a bowl of wine, and throws a styptic powder upon the wound. This ceremony was usually accompanied with great rejoicings and feasting, and it was at this time that the child was named in presence of the company. The Jews invented several superstitious customs at this ceremony, such as placing three stools, one for the circumcisor, the second for the person who holds the child, and the third for Elijah, who, they say, assists invisibly at the ceremony, &c.

The Jews distinguished their proselytes into two sorts, according as they became circumcised or not: those who submitted to this rite were looked upon as children of Abraham, and obliged to keep the laws of Moses; the uncircumcised were only bound to observe the precepts of Noah, and were called *noachidae*.

The Turks never circumcise till the seventh or eighth year, as having no notion of its being necessary to salvation. The Persians circumcise their boys at 13, and their girls from 9 to 15. Those of Madagascar cut the flesh at three several times; and the most zealous of the relations present, catches hold of the prepuce, and swallows it.

Circumcision is practised on women by cutting off the foreskin of the clitoris, which bears a near resemblance and analogy to the prepuce of the male penis. We are told that the Egyptian captive-women were circumcised; and also the subjects of Prester John.

CIRCUMCISION is also the name of a feast, celebrated on the first of January, in commemoration of the circumcision of our Saviour.

CIRCUMDUCTION, in Scots law. When parties in a suit are allowed a proof of allegiances; after the time limited by the judge for taking that proof is elapsed, either party may apply for circumduction of the time of proving; the effect of which is, that no proof can afterwards be brought, and the course must be determined as it stood when circumduction was obtained.

CIRCUMFERENCE, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense, for the curve line which bounds a circle, and otherwise called a *periphery*; the boundary of a right-lined figure being expressed by the term *perimeter*.

CIRCUMFERENTOR, an instrument used by surveyors for taking angles.

It consists of a brass index and circle, all of a piece. The index is commonly about 14 inches long, and an inch and a half broad; the diameter of the circle is about seven inches. On this circle is made a chart, whose meridian line answers to the middle of the breadth of the index, and is divided into 360 degrees. There is a brass ring soldered on the circumference of the circle, on which screws another ring, with a flat glass in it, so as to form a kind of box for the needle, suspended on the pivot in the centre of the circle,

Circumflex
Circus.

Plate lxxiv.
fig. 7.

circle. There are also two fights to screw on, and slide up and down the index; as also a spangle and socket screwed on the back side of the circle for putting the head of the staff in.

How to observe the Quantity of an Angle by the Circumferentor. Let it be required to find the quantity of the angle EKG; first place your instrument at K, with the flower-de-luce of the chart towards you; then direct your sights to E, and observe what degrees are cut by the fourth end of the needle, which let be 296; then, turning the instrument about, direct your sights to G, noting then also what degrees are cut by the fourth end of the needle, which suppose 247. This done, always subtract the lesser from the greater, as in this example, 247 from 296, the remainder is 49 degrees, which is the true quantity of the angle EKG.

CIRCUMFLEX, in grammar, one of the ACCENTS.

CIRUMGYRATION, denotes the whirling motion of any body round a centre: such is that of the planets round the sun.

CIRCUMLOCUTION, a paraphractical method of expressing one's thoughts, or saying that in many words which might have been said in few.

CIRCUMPOLAR STARS, an appellation given to those stars, which, by reason of their vicinity to the pole, move round it without setting.

CIRCUMPOTATIO, in antiquity, a funeral feast provided in honour of the dead. This was very frequent among the ancient Romans, as well as among the Athenians. Solon at Athens, and the decemviri at Rome, endeavoured to reform this custom, thinking it absurd that mirth and drunkenness should mingle with sorrow and grief.

CIRCUMSCRIBED, in geometry, is said of a figure which is drawn round another figure, so that all its sides or planes touch the inscribed figure.

CIRCUMSCRIPTION, in natural philosophy, the termination, bounds, or limits of any natural body.

CIRCUMSTANCE, a particularity which, though not essential to any action, yet doth some way affect it.

CIRCUMSTANTIBUS, in law, a term used for supplying and making up the number of jurors (in case any impanelled appear not, or appearing are challenged by any party,) by adding to them so many of the persons present as will make up the number, in case they are properly qualified.

CIRCUMVALLATION, or *Line of Circumvallation*, in the art of war, is a trench bordered with a parapet, thrown up quite round the besieger's camp, by way of security against any army that may attempt to relieve the place, as well as to prevent desertion.

CIRCUMVOLUTION, in architecture, denotes the torus of the spiral line of the Ionic volute.

CIRCUS, in antiquity, a great building of a round or oval figure, erected by the ancients, to exhibit shews to the people. See *Circensian Games*.

The Roman circus was a large oblong edifice, arched at one end, encompassed with porticoes, and furnished with two rows of seats, placed ascending over each other. In the middle was a kind of foot-bank,

or eminence, with obelisks, statues, and posts at each end. This served them for the courses of their bigae and quadrigae.

Those that have measured the circus say, that it was 2187 feet long, and 960 broad; so that it was the greatest building in Rome: some say it would contain 150,000 people, other 260,000, or 300,000.

CIRENCESTER, an ancient town of Gloucestershire in England. It was strongly fortified with walls and a cattle in the time of the Romans. The ruins of the walls and street are, or were lately, to be seen in the adjacent meadows, where many Roman coins, chequered pavements, and inscriptions on marble, have been found. Two of the Roman consular ways cross each other at this town. The off-ways, which comes from Scotland, passes through this county and town to Totnes in Devonshire. The other, called *Irmis-street*, comes from Gloucester, and runs along to Southampton. Not many years ago they discovered, by digging in a meadow near the town, an ancient building under ground, 50 feet long, 40 broad, and 4 high, and supported by 100 brick pillars, curiously inlaid with stones of various colours, supposed to have been a Roman bath. Cirencester has now but one church, in the windows of which are the remains of very valuable painted glass. The town is governed by 2 high constables, and 14 wards-men, who govern 7 distinct wards; and it sends two members to parliament. It has a free-school, a charity-school, with several almshouses; and is seated on the river Churn, 36 miles north-east of Bristol, and 88 west by north of London. W. Long. 2° . 2. N. Lat. 51° . 42.

CIRENZA, a city of Naples, capital of the Basilicate, with an archbishop's see. It was formerly a considerable place, but is now of small consequence. It is seated on the river Brandano, at the foot of the Appennine mountains, in E. Long. 16. 44. N. Lat. 40° . 48.

CIRO-FERRI, an excellent Italian painter and architect, was born at Rome in 1614, and was the disciple of Peter de Cortona, whose designs he imitated with such exactness, that it is difficult to distinguish them. He was esteemed by pope Alexander VII. and his three successors, and died at Rome in 1689.

CIRRUS, or **CIRRUS**, in botany, a clasper or tendril; that fine spiral string or fibre put out from the foot-stalks, by which some plants, as the ivy and vine, fasten themselves to walls, pales, or trees, for support. The term is synonymous to the capreolus, clavicular, and viticulus of other botanists; and is ranked by Linnaeus among the fulcra, or parts of plants that serve for protection, support, and defence.

Tendrils are sometimes placed opposite to the leaves, as in the vine; sometimes at the side of the foot-stalk of the leaf, as in passion-flower; and sometimes, as in winged pea, *pisum ocheus*, they are emitted from the leaves themselves. With respect to composition, they are either simple, that is, composed of one fibre or chord, as in the vetch; or compound, that is, consist of two, three, or more, as in the everlasting pea. Bitter sweet, solanum, dukamara, bignonia, and ivy, send forth tendrils which plant themselves like roots

Cirencester
Circus.

Cirri
Ciffoid.

in the adjacent walls, or the bark of the neighbouring trees. Claspers, says the ingenious Dr Grew, are like trunk-roots, a mean betwixt a root and a trunk, but a compound of both, as may be gathered from their circinvolutions, in which they mutually ascend and descend. In the mounting of the trunk, continues the same author, claspers serve for support. Thus, in vines, the branches being very long, fragile and slender, would be liable to frequent breaking, unless, by means of their claspers, they were mutually contained together; so that the whole care is divided betwixt the gardener and nature: the former, with his ligaments of leather, secures the main branches; and nature, with those of her own providing, secures the lefs. Their aptitude to this end is seen in their convolutions, a motion not proper to any other-part: and also in their toughness, which is so much the more remarkable, as they are slenderer than the branches from which they proceed. In the trailing of the trunk, tendrils serve for stabilitment and shade: thus, in cucumbers, the trunk and branches being long and fragile, would be driven to and fro, by the winds, to the great prejudice both of themselves and their tender fruits, were they not, by these ligaments, held fast together, and preserved in association and good fellowship. The same claspers serve likewise for shade: so that a natural arbour is formed by the branches of the cucumber, in the same manner as an artificial one is made by tangling together the twigs of trees; for the branches, by the linking of their claspers, being couched together, the tender fruits lie under the umbrage of a bower made of their own leaves. Molt of the pea-bloom flowers have twining claspers, that is, which wind to the right and back again.

CIRRI, in ichthyology, certain oblong and soft appendages, not unlike little worms, hanging from the under jaws or mouths of some fishes: these cirri, commonly translated *beards*, afford marks to distinguish the different species of the fishes on which they are found.

CISALPINE, any thing on this side the Alps. The Romans divided Gaul and the country now called Lombardy, into Cisalpine and Transalpine. That which was Cisalpine with regard to the Romans, is Transalpine with regard to us.

CISLEU, in Hebrew chronology, the ninth month of their ecclesiastical, and third of their civil, year, answering nearly to our November.

CISSAMPELOS, in botany, a genus of the monogynia order, belonging to the dioecia class of plants. There are two species, the pareina and caepeba, both natives of the warmest parts of America. The root of the second, applied externally, is said to be an antidote against the bites of venomous serpents. The plant being infused in water, quickly fills the liquor with a mucilaginous substance, which is as thick as jelly; whence the name of *freezing-lyth*, by which this genus of plants has been distinguished by the Brazilians.

CISSOID, in geometry, a curve of the second order, first invented by Diodes, whence it is called the *ciffoid of Diodes*. See FLUXIONS.

CISSUS, the WILD-GRAPE, a genus of the mono-

gynia order, belonging to the tetrandria class of plants. There are four species, all of them natives of the island of Jamaica, and some of the other islands in the warm parts of America. They send out slender branches, having tendrils at their joints, by which they falten to the neighbouring trees, bushes, and any other support, mounting to a considerable height. The fruit of some of the species are eaten by the negroes.

CISTERCIANS, in church-history, a religious order founded in the 11th century by St Robert, a benedictine. They became so powerful, that they governed almost all Europe, both in spirituals and temporals. Cardinal de Vitri describing their observances, says, they neither wore skins nor shirts; nor ever eat flesh, except in sickness; and abstained from fill, eggs, milk, and cheese: they lay upon straw-beds, in tunics and cowls: they rose at midnight to prayers: they spent the day in labour, reading and prayer: and in all their exercises observed a continual silence. The habit of the cistercian monks is a white robe, in the nature of a cassock, with a black scapulary and hood, and is girt with a wooden girdle. The nuns wear a white tunic, and a black scapulary and girdle.

CISTERN, denotes a subterranean reservoir of rain-water; or a vessel serving as a receptacle for rain or other water, for the necessary uses of a family. There are likewise lead-cisterns, jar-cisterns, &c.

Authors mention a cistern of Constantinople, the vaults of which are supported by two rows of pillars, 212 in each row, each pillar being two feet in diameter. They are planted circularly, and *in radii* tending to that of the centre.

Anciently there were cisterns all over the country in Palestine. There were some likewise in cities and private houses. As the cities for the most part were built on mountains, and the rains fell regularly in Judea at two seasons in the year only, in spring and autumn, people were obliged to keep water in cisterns in the country for the use of their cattle, and in cities for the convenience of the inhabitants. There are still cisterns of very large dimensions to be seen in Palestine, some whereof are 150 paces long, and 54 wide. There is one to be seen at Ramah of 32 paces in length, and 28 in breadth. Wells and cisterns, springs and fountains, are generally confounded in scripture-language.

CISTUS, the ROCK-ROSE; a genus of the monogynia order, belonging to the polyandria class of plants. There are 37 species, most of them natives of the southern parts of Europe, but hardly enough to bear the open air in this country. They are beautiful evergreen shrubs, generally very branchy quite from the bottom, and forming diffused heads. They are very ornamental in gardens, not only as evergreens, making a fine variety at all seasons with their leaves of different figures, sizes, and shades of green and white, but also as first-rate flowering shrubs, being very profuse in most elegant flowers of white, purple, and yellow colours. These flowers only last for one day; but there is a continual succession of new ones for a month or six weeks on the same plant; and when there are different species, they will exhibit

Cisterciens
Cistus.

Citadel
Citizen.

exhibit a constant bloom for near three months. They are propagated either by seeds or cuttings, and thrive best in a dry soil. Their proper situation in shrubbery works should be towards the front of the clumps and other compartments, in assemblage with the choicest shrubs of similar growth, disposing them so as to make a variety, and to have shelter from the other plants; but they ought by no means to be crowded. Gum labdanum is found upon a species of citrus which grows naturally in the Levant, and is therefore called *ladanifera*. See LABDANUM.

CITADEL, a place fortified with five or six bastions, built on a convenient ground near a city, that it may command it in case of a rebellion.

CITADELLA, the capital town in the island of Minorca, in the Mediterranean, with a new harbour. This, with the whole island, were taken by general Stanhope and the confederate fleet in 1708, and ceded to Great Britain by the treaty of Utrecht in 1713; but it was taken by the French, after a brave defence, in 1756; and restored by the peace. It is 27 miles west of Port-Mahon. E. Long. 3. 30. N. Lat. 39. 58.

CITADINESCA, in natural history, a name given by some writers to the Florentine marble, which is supposed to represent towns, palaces, ruins, rivers, &c. These delineations are merely accidental, and are commonly much assisted by the imagination, though the natural lines of a stone may sometimes luckily enough represent the ruins of some ancient building, or the course of a river. In England there is a kind of septaria, or ludus Helmontii, which has sometimes pretty beautiful, though very irregular, delineations of this kind. The Florentine marble, as we see it wrought up in the ornaments of cabinets, &c. owes a great deal to the skill of the workmen, who always pick out the proper pieces from the mass, and dispose them in the work so as to represent what they please.

CITATION, in ecclesiastical courts, is the same with summons in civil courts. See SUMMONS.

CITATION, is also a quotation of some law, authority, or passage of a book.

CITHARA, in antiquity, a musical instrument, the precise structure of which is not known; some think it resembled the Greek delta Δ ; and others, the shape of a half moon. At first it had only three strings, but the number was at different times increased to 8, to 9, and lastly to 24. It was used in entertainments and private houses, and played upon with a plectrum or quill, like the lyre.

CITHAREXYLON, FIDDLE-WOOD; a genus of the angiosperma order, belonging to the didymia class of plants. There are two species, both natives of the warm parts of America, where they grow to be large trees, and are adorned with white flowers growing in spikes. In Britain they appear only as shrubs, and must be constantly retained in the stove, where they make a fine appearance, being beautiful evergreens. They may be propagated either by seeds or cuttings.

CITIZEN, a native or inhabitant of a city, vested with the freedom and liberties of it.

A citizen of Rome was distinguished from a stranger, because he belonged to no certain commonwealth subject to the Romans. A citizen is either by birth

or election; and sons may derive the right from their fathers. To make a good Roman citizen, it was necessary to be an inhabitant of Rome, to be enrolled in one of the tribes, and to be capable of dignities. Those to whom were granted the rights and privileges of Roman citizens, were only honorary citizens. It was not lawful to scourge a citizen of Rome.

CITRINUS, in natural history, the name of a peculiar species of sprig crystal, which is of a beautiful yellow. Many of the common crystals, when in the neighbourhood of lead-mines, are liable to be accidentally tinged yellow, by an admixture of the particles of that metal; and all these, whether finer or coarser, have been too frequently confounded together under the name *citrine*; but Dr Hill has ascertained this to be a peculiar species of crystal different from all the others in form as well as in colour; and distinguished by the name of *ellipsonacrossylum lucidum flavescens, pyramidæ brevis*. It is never found colourless like the other crystals, but has great variety of tinges, from that of the deeper ochres, to a pale lemon-colour. It is very plentiful in the West Indies, and is sometimes found in Bohemia. Our jewellers have learned from the French and Italians, who are very fond of it, to call it *citrine*; and often cut stones for rings out of it, particularly out of the pyramid, which is always finer than the column, and these, after they have passed through two or three hands, are generally mistaken for topazes.

CITRON-TREE, in botany. See CITRUS.

CITRON-Water, a well-known strong water or cordial, which may be thus made: Take of fine thin lemon-peel, 18 ounces; of orange-peel, 9 ounces; perfect nutmegs, 4 ounces; the finest and best rectified spirit of wine, 2 gallons and a half. Digest in balneo mariæ for one night: draw off with a slow fire: then add as much water as will just make the matter milky (which will be about 7 quarts or 2 gallons); and lastly, add 2 pounds of fine sugar. This composition may be improved by fresh elder flowers, hung in a cloth in the head of the still, sprinkled with ambergrace in powder, or its essence.

CITRON-Wood, the wood of an American tree, called by the natives *candle-wood*; because, being cut into splinters, it burns like a candle. The tree is frequent in the Leeward Islands, and grows to a considerable size: the leaves are like those of the bay-tree, but of a finer green; the flower is sweet, and much like those of the orange; the fruit succeeding these is black, and of the size of a pepper-corn. The trunk is so like the yellow Saunders in colour, that there was once an opinion that it was the same tree, and much of it was imported into Europe, and sold as such: but they were soon found to be different; the Saunders being of a sweet scent, and but moderately heavy and resinous; but the citron-wood considerably heavy, very oily, and of a strong smell. It is of no known use in medicine; but is used in France and Germany by the turners, being a fine firm-grained wood, and taking a fine polish, and with age becoming of a very beautiful brown.

CITRUS, the CITRON-TREE, a genus of the icofandria order, belonging to the polyadelphia class of plants.

Citrus
Citrus.

Species I. The Medica, or Citron-tree, hath an upright smooth trunk, divided at top into a branchy strong-shooting, full head, from about five to 15 feet high, adorned with large oval, spear-shaped, thick leaves, having linear foot-stalks, and numerous flowers from the sides of the branches, succeeded by very large oblong oval, pointed, rough-rinded fruit. The varieties are citron-tree with four fruit; with sweet fruit; with long fruit; with warted fruit; with recurved fruit; and with blotched leaves.

II. *The Lima, or Lemon-tree*, hath an upright smooth trunk, divided upward into a branchy regular head; from 12 to 15 feet high; large, oval, spear-shaped, pointed, slightly sawed leaves, on linear foot-stalks; and many flowers from the sides of the branches succeeded by large oval fruit prominent at the top. The varieties are, the lemon-tree with four fruit; with sweetish fruit; with very large fruit called Imperial lemon; with pear-shaped fruit; with furrowed fruit; with clustered fruit; with chinking fruit; with whitish fruit; with tricolor striped fruit; with silver striped leaves; and with double flowers.

III. *The Aurantium, or Orange-tree*, hath an upright trunk dividing upward into a branchy, regular head, from five to 10 or 12 feet high; oval, spear-shaped, entire leaves, having winged foot-stalks and numerous white flowers at the sides of the branches, succeeded by globular fruit compressed at both ends. The most noted varieties are, 1. *The Seville orange*. This is a very handsome tree, and the hardiest of any; as in this country it shoots freely, produces large and beautiful leaves, flowers stronger, &c. The fruit is large, rough rinded, and four, of excellent quality for economical uses. 2. *The China orange*. This tree has moderately sized leaves, and a smooth, thin-rinded, sweet fruit, of which there are several varieties in warm countries, where they grow in the open ground. 3. *The great Shaddock orange, or pumplemoos*, grows larger and stronger than the foregoing, with large, thick and somewhat serrated leaves, and very large fruit, having a reddish pulp. It derives the name of Shaddock from one of that name that first brought it from the East Indies. 4. *The Horned orange* is a tree of moderate size, producing fruit which divide, and the rind runs out into divisions like horns. 5. *The Hermaphrodite orange* is a common sized tree, producing fruit shaped partly like an orange and partly like a citron. 6. *The Dwarf orange tree, or nutmeg orange*, has a long stem and small bushy head, growing two or three feet high; small oval leaves in clusters; and numerous flowers in clusters, covering the branches, succeeded by very small fruit. These are the most remarkable varieties of the three foregoing species of citrus: but besides these there are a great number of others; and indeed, in those countries where they grow naturally, the varieties may be multiplied without end, like those of our apples and pears. The flowers of all the species and varieties are formed each of five spreading petals, appearing here principally in May and June; and the fruit continue setting in June and July, and ripen the year following.

IV. *The Trifoliata, or Japonice citron*, is a thorny shrub growing naturally in Japan, where it is likewise known by the names of Gces, and Karats banna.

The trunk, we are told by Kæmpfer, acquires by age and culture the thickness of a tree. The branches and shoots are unequal; in some parts compressed, in others swelling, especially about the spines. These proceed singly from the stem and branches; are straight, run out from a broad base into a very sharp point; and are protruded from the wood, with the common bark of which they are likewise invested. The wood is loose and soft; the bark of a shining green, moist, and easily parting from the wood. The leaves are few in number, fewed on the edges, veined, placed without order, but generally growing under the spines. They grow by threes, like those of trefoil, upon the extremity of a common foot-stalk which is furnished on each side with a membranaceous fringe or margin, somewhat resembling the pedicles of the orange. The upper surface of the leaves is of a bright lucid green, the lower dark and herbaceous. The flowers which resemble those of the medlar, proceed singly from the arm-pits of the leaves; are white, possessed of no great degree of fragrance, and consist of five petals. The fruit is equally beautiful with a middle sized orange; their internal structure is also pretty much the same; only the pulp is glutinous, of an unpleasant smell, and a harsh disagreeable taste. The seeds have the same taste with the pulp, and are shaped exactly like those of the orange.

Culture. The three first species merit particular attention. They are elegant evergreens, rising in this country from about five to 10 feet in height; forming full and handsome heads, closely garnished with beautiful large leaves all the year round, and putting forth a profusion of sweet flowers in spring and early in summer; which even in this climate are often succeeded by abundance of fruit that sometimes arrive at tolerable perfection. Though all the varieties were originally obtained by seed, yet the only certain method of continuing the approved varieties is by budding or inarching them on stocks raised from seed to a proper size. As the young trees, however, are brought in plenty from abroad, this method is seldom practised in this country: but for curiosity, it may be done by those who are so inclined, in the following manner: Early in the spring procure some kernels, which may be had in plenty from rotten fruits, or others that are properly ripened, observing that for stocks, the citron, lemon, and Seville-orange, as being the sweetest shooters are to be preferred; and of these the citron is the strongest. Sow the kernels in March, in pots of rich light earth half an inch deep, and plunge them in a hot-bed under frames and glasses. Dung or tan may be used, but the latter is preferable, giving air, and frequent sprinklings of water. In two or three weeks the plants will come up, and in six or eight weeks more; they will be advanced four or five inches or more in height. You must now give them more air and water; and about the middle of June harden them to the full air, in which let them remain till October; then move them into the green house, to stand till the spring, and in March or April, plant them singly in small pots; being careful to shake them out of the seed pots with their roots entire. They must be watered immediately after planting, and the watering must be occasionally repeated. After this they are to be treated

Citrus.

ed as woody exotics of the green-house; and in a year or two the largest of those designed for stocks will be fit for budding.

* See *Inoculation*.

The operation for budding is performed in the month of August, and is done in the common way*; only the buds must be taken from trees of a good kind that bear well. As soon as the operation is finished, the pots with their plants must be placed in the green-house, or in a glass case; or, where there is the convenience of a spare bark-pit, where the heat of the bark is almost exhausted, the pots may be plunged therein for two or three weeks. In either case, however, the air must be admitted freely by opening the front glasses; allowing also a slight shade of mats in the middle of hot sunshine days, and supplying them with water every two or three days during this kind of weather. In three or four weeks the buds will be united with the stock; when it will be proper to loosen the bandages that they may have room to swell; the buds, however, will all remain dormant till the next spring. They may also be propagated by inarching, which is done in the common way†; but the method

† See *Inarching*.

of budding is found to produce much handomer trees, and therefore is to be preferred. But the most cheap and expeditious method of procuring a collection of these kinds of trees is by having recourse to such as are imported from Spain, Italy, and Portugal. These come over in chests, without any earth to their roots, having their roots and heads a little trimmed; they are commonly from one inch to two or three in diameter in the stem; from two to four or five feet in height; and by the assistance of a bark-bed they readily take root and grow freely; forming as good trees in two years, as could be raised here by inarching or budding, in 15 or 20. They are sold in the Italian ware-houses in London; the principal one of which has been for many years in the Hay-market near the bottom, Pall Mall: their price is from three shillings to a guinea each, according to their size; and they are generally advertised as soon as they arrive, which is early in the spring, and the sooner the better. In the choice of these trees it must be observed, that they are commonly budded at such height in the stem, as to form heads from about two to four or five feet high, and as they are frequently furnished with two buds, one on each side of the stem, these should be chosen preferably to others; as they will form the most regular heads. Preparatory to their planting, they must be placed for a day or two in tubs of water to plump their bark and roots; after this they must be washed and cleaned, their branches trimmed to half a foot long, and the roots freed from diseased parts, and all the small dried fibres. Then they are to be planted in pots filled with light rich earth; and plunged in a tan-bed, where they are to remain for three or four months; after which they are to be trained to the open air, but will not bear it longer than from the end of May till the middle or end of October.

Sometimes these trees, instead of being kept in pots or tubs, are planted in the full ground; and where this can be done, it is by far the most eligible method. Where this is intended, there must be frames erected for the support of glass and other covers, to defend the plants during inclement weather; and in this situa-

tion the trees generally shoot strong, produce large fruit, and may be trained either as wall, or standard trees. A south wall, in a dry situation is proper for training them as wall-trees; against which may be erected wooden frame work sloping, either fixed or moveable, for the support of glass frames for winter; likewise for the greater protection of the trees in severe frosts, there may be a fire-place with a flue or two carried along it a low wall, in the front and ends. To have the trees as standards, a more capacious and lofty glass-case should be erected against the wall in the manner of a hot-house, but higher; in this one or two rows of orange-trees may be planted, suffering to run up as standards with only some necessary pruning just to preserve their regularity. In some places there are lofty moveable glass-cases, so that two or three rows of trees are planted in a conspicuous part of the pleasure ground. In winter the frame is put over them, and in summer wholly taken away; so that they appear like a little orange-grove growing in the open ground. The flowering and fruit setting season of all the sorts of citrus is in June and July. They are often, especially the orange-trees, greatly loaded with blossoms; and when these stand very thick, it is proper to thin them a little, taking off the smallest. It is also to be observed, that as the trees continue blowing and setting their fruit for three months, when a full crop of fruit is set, it is of benefit to the trees and fruit, to gather off the superabundant blossoms as they are produced; though some permit them to remain on account of their appearance.

Uses. The fruits of the citron, lemon, and orange trees, yield very agreeable acid juices; which, besides the uses to which they are commonly applied, answer considerable purposes in medicine. When commodore Anson sailed round the world, his men were so surprisingly recovered from the scurvy by the oranges which they found at the island of Tinian, that it was afterwards thought worthy of the attention of government to inquire into the virtues of these fruits as an antiscorbutic medicine. In captain Cook's last voyage, he was supplied with a quantity of orange and lemon juice inspissated to a rob; but his opinion of its efficacy is by no means great. The dearth of it is a great objection; and unless in conjunction with other things, he has not observed its good effects. Sir John Pringle, in his discourse before the Royal Society, when captain Cook was presented with a medal by that respectable body, differs a little from the captain's opinion, and thinks that in the sea-scurvy these fruits must necessarily be very efficacious. He approves, however, more of the juices themselves depurated, than the extract of them; as this cannot be prepared without dissipating many of the finer parts. The juice of lemons is very frequently used for neutralising alkaline salts for saline draughts. The citron is seldom used in this country; though its peel, as well as that of the lemon, is candied, and sold as a sweetmeat. The yellow peel of the lemon is an agreeable aromatic, as is also that of the orange; and in cold plethoric constitutions they prove excellent stomachics and carminatives, promoting appetite, warming the habit, and strengthening the tone of the viscera.

Orange-

Citrus.

Cittern
City.

Orange-peel, however, is very considerably warmer than that of lemons, and abounds more in essential oil: to this circumstance therefore due regard ought to be had in the use of these medicines. The flavour of orange peel is likewise less perishable than that of lemons. Both are ingredients in many official preparations.

The young fruit of the Seville orange dried, are used in medicine under the name of *aurantia curassavensis*. They are moderately warm-bitterish aromatics, of a sufficiently agreeable flavour. The flowers of the orange-tree have been for some time past in great esteem as a perfume. They are highly odoriferous, of a somewhat warm and bitter taste. They yield their flavour by infusion to rectified spirit, and in distillation both to spirit and water: the bitter matter is dissolved in water, and on evaporating the decoction remains entire in the extract. The distilled water was formerly kept in the shops, but on account of the great scarcity of the flowers is now laid aside: it is called by foreign writers *aqua naphæ*. An oil distilled from these flowers, is brought from Italy under the name of *oleum, or essentia neroli*.

CITTERN, a musical instrument much resembling the guitar, for which it has been frequently mistaken. Anciently it was called the *cistrum*, and till lately was held in great contempt both in France and Britain. The practice on it being very easy, it was formerly the amusement and recreation of lewd women and their visitors; inasmuch, that in many of the old English dramatic writers, it is made the symbol of a woman that lived by prostitution. It was also the common amusement of waiting customers in barber's shops, as being the most easy of all instruments to play on, and therefore it was thought that almost every body could make use of it.

CITY, according to Cowel, is a town corporate which hath a bishop and cathedral church; and is called *civitas, oppidum, and urbs*: *civitas*, in regard it is governed by justice and order of magistracy; *oppidum*, because it contains a great number of inhabitants; and *urbs*, because it is in due form surrounded with walls.

Kingdoms have been said to contain as many cities as they have seats of archbishops and bishops: but, according to Blount, *city* is a word that hath obtained since the conquest; for, in the time of the Saxons, there were no cities, but all the great towns were called *burghs*, and even London was then called *Edinburgh*, as the capital of Scotland is called *Edinburgh*. And long after the conquest the word *city* is used promiscuously with the *burgh*, as in the charter of Leicester, where it is both called *civitas* and *burgus*; which shews that those writers were mistaken who tell us every city was, or is, a bishop's see. And though the word *city* signifies with us such a town corporate as hath usually a bishop and a cathedral church, yet it is not always so.

As to the ancient state of cities and villages, whilst the feudal policy prevailed, they held of some great lord on whom they depended for protection, and were subject to his arbitrary jurisdiction. The inhabitants were deprived of the natural and most unalienable rights of humanity. They could not dispose of the

effects which their own industry had acquired, either by a latter-will or by any deed executed during their life. They had no right to appoint guardians for their children during their minority. They were not permitted to marry without purchasing the consent of the lord on whom they depended. If once they had commenced a law-suit, they durst not terminate it by an accommodation, because that would have deprived the lord, in whole court they pleaded, of the perquisites due to him on passing his sentence. Services of various kinds no less disgraceful than oppressive were exacted from them without mercy or moderation. The spirit of industry was checked in some cities by absurd regulations, and in others by unreasonable exactions: nor would the narrow and oppressive maxims of a military aristocracy have permitted it ever to rise to any degree of height or vigour.

Robertson's
Charles V.

The freedom of cities was first established in Italy, owing principally to the introduction of commerce. As soon as they began to turn their attention towards this object, and to conceive some idea of the advantages they might derive from it, they became impatient to shake off the yoke of their insolent lords; and to establish among themselves such a free and equal government as would render property secure, and industry flourishing. The German emperors, especially those of the Franconian and Svanian lines, as the seat of their government was far distant from Italy, possessed a feeble and imperfect jurisdiction in that country. Their perpetual quarrels, either with the popes, or their own turbulent vassals, diverted their attention from the interior police of Italy, and gave constant employment for their arms. These circumstances induced some of the Italian cities, towards the beginning of the 11th century, to assume new privileges; to unite together more closely; and to form themselves into bodies politic, under the government of laws established by common consent. The rights which many cities acquired by bold or fortunate usurpations, others purchased from the emperors, who deemed themselves gainers when they received large sums for immunities which they were no longer able to withhold; and some cities obtained them gratuitously from the facility or generosity of the princes on whom they depended. The great increase of wealth which the Crusades brought into Italy, occasioned a new kind of fermentation and activity in the minds of the people, and excited such a general passion for liberty and independence, that, before the conclusion of the last crusade, all the considerable cities in that country had either purchased or had extorted large immunities from the emperors.

This innovation was not long known in Italy before it made its way into France. Louis the Great, in order to create some power that might counterbalance those potent vassals who controlled or gave law to the crown, first adopted the plan of conferring new privileges on the towns situated within his own domaine. These privileges were called *charters of community*, by which he enfranchised the inhabitants, abolished all marks of servitude, and formed them into corporations or bodies politic, to be governed by a council and magistrates of their own nomination. These magistrates had the right of administering justice

City.

tice within their own precincts; of levying taxes; of embodying and training to arms the militia of the town, which took the field when required by the sovereign, under the command of officers appointed by the community. The great barons imitated the example of their monarch, and granted like immunities to the towns within their territories. They had wasted such great sums in their expeditions to the Holy Land, that they were eager to lay hold on this new expedient for raising money, by the sale of those charters of liberty. Though the constitution of communities was as repugnant to their maxims of policy as it was adverse to their power, they disregarded remote consequences in order to obtain present relief. In less than two centuries, servitude was abolished in most of the cities of France, and they became free corporations, instead of dependent villages without jurisdiction or privileges. Much about the same period the great cities of Germany began to acquire like immunities, and laid the foundations of their present liberty and independence. The practice spread quickly over Europe, and was adopted in Spain, England, Scotland, and all the other feudal kingdoms.

The Spanish historians are almost entirely silent concerning the origin and progress of communities in that kingdom; so that it is impossible to fix with any degree of certainty the time and manner of their first introduction there. It appears, however, from Mariana, that in the year 1350 eighteen cities had obtained a seat in the Cortes of Castile. In Aragon, cities seem early to have acquired extensive immunities together with a share in the legislature. In the year 1118, the citizens of Saragossa had not only attained political liberty, but they were declared to be of equal rank with the nobles of the second class; and many other immunities, unknown to persons in their rank of life, in other parts of Europe were conferred upon them. In England the establishment of communities or corporations was posterior to the conquest. The practice was borrowed from France, and the privileges granted by the crown were perfectly similar to those above enumerated. It is not improbable that some of the towns in England were formed into corporations under the Saxon kings, and that the charters, granted by the kings of the Norman race, were not charters of enfranchisement from a state of slavery, but a confirmation of privileges which they had already enjoyed.* The English cities, however, were very inconsiderable in the 12th century. A clear proof of this occurs in the history just referred to. Fitz-Stephen, a contemporary author, gives a description of the city of London in the reign of Henry II. and the terms in which he speaks of its trade, its wealth, and the number of its inhabitants, would suggest no inadequate idea of its state at present, when it is the greatest and most opulent city in Europe. But all ideas of grandeur and magnificence are merely comparative. It appears from Peter of Blois, archdeacon of London, who flourished in the same reign, and who had good opportunity of being informed, that this city, of which Fitz-Stephen gives such a pompous account, contained no more than 40,000 inhabitants. The other cities were small in proportion, and in no condition to extort any extensive privileges. That

the constitution of the boroughs of Scotland, in many circumstances resembled that of the towns of France and England, is manifest from the *Leges Burgorum*, annexed to the *Regiam Majestatem*.

CIVET, a kind of perfume which bears the name of the animal it is taken from, and to which it is peculiar. See VIVERRA.

Good civet is of a clear, yellowish, or brownish colour; not fluid nor hard, but about the consistence of butter or honey, and uniform throughout; of a very strong smell, quite offensive when undiluted, but agreeable when only a small portion of civet is mixed with a large one of other substances. It unites easily with oils both expressed and distilled, but not at all with water, or spirit of wine: nor can it be rendered miscible with water by the meditation of sugar. The yolk of an egg seems to dispose it to unite with water; but in a very little while the civet separates from the liquor and falls to the bottom, tho' it does not prove of such a resinous tenacity, as when treated with sugar and spirit of wine. It communicates, however, some share of its smell both to watery and spirituous liquors: hence a small portion of it is often added in odoriferous tinctures, and suspended in the still-head during the distillation of odoriferous waters and spirits. It is rarely, if ever employed for medicinal purposes. The Italians make it an ingredient in perfumed oils, and thus obtain the whole of its scent; for oils wholly dissolve the substance of it. It is very rare, however, to meet with civet unadulterated. The substances usually mixed with it are lard and butter; which agreeing with it in its general properties, render all criteria for distinguishing the adulteration impossible. A great trade of civet is carried on at Calicut, Bassora, and other parts of the Indies, and in Africa, where the animal that produces the perfume is found. Live civet-cats are to be seen also in France and Holland. The French keep them only as a rarity; but the Dutch, who keep a great number, draw the civet from them for sale. It is mostly used by confectioners and perfumers.

CIVET-Cat, the English name of the animal which produces the civet. See VIVERRA.

CIVIC CROWN, was a crown given by the ancient Romans to any soldier who had saved the life of a citizen in an engagement.

The civic crown was reckoned more honourable than any other crown, though composed of no better materials than oak-boughs. Plutarch, in the life of C. M. Coriolanus, accounts as follows, for using on this occasion the branches of this tree before all others: because, says he, the oak wreath being sacred to Jupiter, the great guardian of their city, they thought it the most proper ornament for him who had preserved the life of a citizen. Pliny*, speaking of the honour and privileges conferred on those who had merited this crown, says, "They who had once obtained it, might wear it always. When they appeared at the public spectacles, the senate and people rose to do them honour, and they took their seats on these occasions among the senators. They were not only personally excused from all troublesome offices, but procured the same immunity for their father and grandfather by the father's side."

CIVIDAD.

Cives
h
Civic.

* See Lord Lyttelton's *History of Henry II.* vol. 2. B. 317.

* Lib. 16.
cap. 4.

CIVIDAD-DE-LAS-PALMAS, the capital town of the island of Canary, with a bishop's see, and a good harbour. The houses are well-built, two stories high, and flat-roofed. The cathedral is a very handsome structure; and the inhabitants are gay and rich. The air is temperate, and free from extremes of heat and cold. It is defended by a small castle seated on a hill. W. Long. 14. 35. N. Lat. 28. 0.

CIVIDAD-REAL, a town of Spain, in New Castile, and capital of La Mancha. The inhabitants are noted for dressing leather extremely well for gloves. W. Long. 4. 15. N. Lat. 39. 2.

CIVIDAD-RODRIGO, a strong and considerable town of Spain, in the kingdom of Leon, with a bishop's see. It is seated in a fertile country, on the river Aquada, in W. Long. 6. 52. N. Lat. 40. 38.

CIVIDAD-di-FRIULI, a small, but ancient town of Italy, in Friuli, and in the territory of Venice; seated on the river Natifona. E. Long. 13. 25. N. Lat. 46. 15.

CIVIL, in a general sense, something that regards the policy, public good, or peace of the citizens, or subjects of the state; in which sense we say, civil government, civil law, civil right, civil war, &c.

CIVIL, in a legal sense, is also applied to the ordinary procedure in an action, relating to some pecuniary matter or interest, in which sense it is opposed to criminal.

CIVIL Death, any thing that cuts off a man from civil society; as a condemnation to the galleys, perpetual banishment, condemnation to death, outlawry, and excommunication.

CIVIL Law, is properly the peculiar law of each state, country, or city: but what we usually mean by the civil law, is a body of laws composed out of the best Roman and Grecian laws, compiled from the laws of nature and nations; and, for the most part, received and observed throughout all the Roman dominions for above 1200 years. See **LAW**, Part I. n° 43, 44.

CIVIL Society. See **LAW**, Part I. n° 12.

CIVIL State, in the British polity, one of the general divisions of the **LAITY**, comprehending all orders of men from the highest nobleman to the meanest peasant that are not included under the **MILITARY** or **MARITIME** states: though it may sometimes include individuals of these as well as of the **CLERGY**; since a nobleman, a knight, a gentleman, or a peasant, may become either a divine, a soldier, or a seaman. The division of this state is into **NOBILITY** and **COMMONALTY**; see these articles.

CIVIL War, a war between people of the same state, or the citizens of the same city.

CIVIL Year, is the legal year, or annual account of time, which every government appoints to be used within its own dominions; and is so called in contradistinction to the natural year, which is measured exactly by the revolution of the heavenly bodies.

CIVILIAN, in general, denotes something belonging to the civil law; but more especially the doctors and professors thereof are called *civilians*.

CIVITA-DI-PENNA, an ancient town of Italy, in the kingdom of Naples, and in the Farther Abruzzo, with a bishop's see. It is situated near the river Salvo. Vol. III.

no, 25 miles north east of Aquila. E. Long. 13. 3. N. Lat. 42. 25.

CIVITA-Castellana, a town of Italy, in St Peter's patrimony, seated on a river, which, seven miles from thence, falls into the Tiber. E. Long. 13. 3. N. Lat. 42. 15.

CIVITA-Turchino, a place in Italy, about two miles north of the town of Corneto in the patrimony of St Peter. It is an hill of an oblong form, the summit of which is almost one continued plain. From the quantity of medals, intaglios, fragments of inscriptions, &c. that are occasionally found here, this is believed to be the very spot where the ancient and powerful city of Tarquinii once stood. At present it is only one continued field of corn. On the south-east side of it runs the ridge of a hill which unites it to Corneto. This ridge is at least three or four miles in length, and almost entirely covered with artificial hillocks, called by the inhabitants *monti rossi*. About twelve of these hillocks have at different times been opened; and in every one of them have been found several subterranean apartments cut out of the solid rock. These apartments are of various forms and dimensions: some consist of a large outer room, and a small one within; others of a small room at the first entrance, and a large one within: others are supported by a column of the solid rock left in the centre, with openings on every part. The entrance to them all is by a door about five feet high, by two and a half broad. Some of them have no light but from the door, while others seem to have had a small light from above, through an hole of a pyramidal form.

Many of these apartments have an elevated port that runs all round the wall, being a part of the rock left for that purpose. The moveables found in these apartments consist chiefly of Etruscan vases of various forms: in some indeed have been found some plain sarcophagi of stone, with bones in them. The whole of these apartments are stuccoed, and ornamented in various manners: some indeed are plain; but others, particularly three, are richly adorned, having a double row of Etruscan inscriptions running round the upper part of the walls, and under them a kind of frieze of figures in painting: some have an ornament under the figures, which seems to supply the place of an architecture. The paintings seem to be in fresco; and in general resemble those which are usually seen upon Etruscan vases; though some of them are perhaps superior to any thing as yet seen of the Etruscan art in painting. In general they are slight, but well conceived; and prove, that the artist was capable of producing things more studied and better finished; though in such a subterraneous situation, the delicacy of a finished work would in a great measure have been thrown away. It is probable, however, that among the immense number of these apartments that yet remain to be opened, many paintings and inscriptions may be found sufficient to form a very useful and entertaining work. At present this great scene of antiquities is almost entirely unknown, even in Rome. Mr Jenkins resident at Rome, was the first Englishman who visited it.

CIVITA-Pecchia, a sea-port town of Italy in the patrimony of St Peter, with a good harbour and an arsenal.

Civoli
|
Clamp.

arsenal. Here the Pope's galleys are stationed, and it has lately been made a free port; but the air is very unwholesome. E. Long. 12. 31. N. Lat. 45. 5.

CIVOLI, or **CIGOLI**, (Lewis), an Italian painter, whose family-name was *Gardi*, was born at the castle of Cigoli, in Tuscany, in the year 1559. His *ecce homo*, which he performed as a trial of skill with Barocchio and Michael Angelo da Caravaggio, was judged better than those executed by them. He excelled in designing, and was employed by the popes and princes of his time. He died at Rome in 1613.

CLACK, among countrymen. To clack wool, is to cut off the sheep's mark, which makes the weight less, and yields less custom to the king.

CLACKMANNAN, the name of a small shire in Scotland, not exceeding eight miles in length, and five in breadth. It is bounded on the north by the Ochil hills; on the south, by the frith of Forth; on the east, by Perth-shire; and on the west, by Stirling-shire. The country is plain and fertile towards the frith, producing corn and pasture in abundance. It likewise yields great quantities of excellent coal, which is exported to England, France, and Holland. It is watered by the rivers Forth and Devan, and joins the shire of Kinross in sending a member alternately to parliament.

CLACKMANNAN, a small town of Scotland, and capital of the county of that name, is situated on the northern shore of the Forth, in W. Long. 3. 40. N. Lat. 56. 15. It stands on a hill, on the top of which is the castle, commanding a noble prospect. It was long the seat of the chief of the Bruces, who was hereditary sheriff of the county before the jurisdictions were abolished. The large square tower is called after the name of *Robert Bruce*; whose great sword and casque are still preserved here. The hill is prettily wooded; and, with the tower, forms a picturesque object.

CLAGENFURT, a strong town of Germany, and capital of Carinthia, situated in E. Long. 13. 56. N. Lat. 46. 50.

CLAGET (William), an eminent and learned divine, born in 1646. He was preacher to the society of Gray's Inn; which employment he exercised until he died in 1688, being then also one of the king's chaplains. Archbishop Sharp gives him an excellent character; and bishop Burnet has ranked him among those worthy men whose lives and labours contributed to rescue the church from the reproaches which the follies of others had drawn upon it. Dr Claget published several things; but his principal work is his "Discourse concerning the Operations of the Holy Spirit;" nor must it be forgotten that he was one of those excellent divines who made a noble stand against the designs of James II. to introduce popery. Four volumes of his sermons were published after his death by his brother Nicholas Claget, archdeacon of Sudbury, father of Nicholas Claget afterwards bishop of Exeter.

CLAIM, in law, a challenge of interest in any thing that is in the possession of another.

CLAM, in zoology, a shell-fish. See **VENUS**.

CLAMP, a piece of wood joined to another.

CLAMP is likewise the term for a pile of unburnt

bricks built up for burning. These clamps are built much after the same manner as arches are built in kilns, viz. with a vacuity betwixt each brick's breadth for the fire to ascend by; but with this difference, that instead of arching, they truss over, or over-span; that is, the end of one brick is laid about half way over the end of another, and so till both sides meet within half a brick's length, and then a binding brick at the top finishes the arch.

CLAMP in a Ship, denotes a piece of timber applied to a mast or yard to prevent the wood from bursting; and also a thick plank lying fore and aft under the beams of the first orlop, or second deck, and is the same that the riling timbers are to the deck.

CLAMP-Nails, such nails as are used to fasten on clamps in the building or repairing of ships.

CLAMPING, in joinery, is the fitting a piece of board with the grain, to another piece of board cross the grain. Thus the ends of tables are commonly clamped, to prevent their warping.

CLANDESTINE, any thing done without the knowledge of the parties concerned, or without the proper solemnities. Thus a marriage is said to be clandestine, when performed without the publication of bans, the consent of parents, &c.

CLANS, in history, and particularly in that of Scotland. The nations which over-ran Europe were originally divided into many small tribes; and when they came to parcel out the lands which they had conquered, it was natural for every chieftain to bestow a portion, in the first place, upon those of his own tribe or family. These all held their lands of him; and as the safety of each individual depended on the general union, these small societies clung together, and were distinguished by some common appellation, either patronymical, or local, long before the introduction of surnames or ensigns armorial. But when these became common, the descendants and relations of every chieftain assumed the same name and arms with him; other vassals were proud to imitate their example; and by degrees they were communicated to all those who held of the same superior. Thus clanships were formed; and, in a generation or two, that consanguinity, which was at first in a great measure imaginary, was believed to be real. An artificial union was converted into a natural one: men willingly followed a leader, whom they regarded both as the superior of their lands, and the chief of their blood; and served him not only with the fidelity of vassals, but the affection of friends. In the other feudal kingdoms, we may observe such unions as we have described, imperfectly formed; but in Scotland, whether they were the production of chance, or the effect of policy, or strengthened by their preserving their genealogies both genuine and fabulous, clanships were universal. Such a confederacy might be overcome; it could not be broken; and no change of manners or government has been able, in some parts of the kingdom, to dissolve associations which are founded upon prejudices so natural to the human mind. How formidable were nobles at the head of followers, who, counting that cause just and honourable which their chief approved, were ever ready to take the field at his command, and to sacrifice their lives in defence of his person or

Scotland.

Clap
Clarichord.

of his fame? Against such men a king contended with great disadvantage; and that cold service, which money purchases, or authority extorts, was not an equal match for their ardour and zeal.

Some imagine the word *clan* to be only a corruption of the Roman *colonia*; but Mr Whittaker asserts it to be purely British, and to signify a *family*.

CLAP, in medicine, the first stage of the venereal disease, more usually called a GONORRHOEA.

CLAP-Net, in birding, a sort of net contrived for the taking of larks with the looking-glass, by the method called *during* or *doring*. The nets are spread over an even piece of ground, and the larks are invited to the place by other larks fastened down, and by a looking-glass composed of five pieces, and fixed in a frame so that it is turned round very swiftly backwards and forwards, by means of a cord pulled by a person at a considerable distance behind a hedge. See DORING.

CLAR, or CLAER, in metallurgy, bone-ashes perfectly calcined, and finely powdered, kept purposely for covering the insides of COPPELS.

CLARAMONT-POWDER, a kind of earth, called *terra de Baira*, from the place where it is found: it is famous at Venice, for its efficacy in stopping hæmorrhages of all kinds, and in curing malignant fevers.

PRECEPT of CLARE CONSTAT, in Scots law, the warrant of a superior for entering and infesting the heir of his former vassal, without the interposition of an inquest. See LAW, Part III. n^o clxxx. 28.

CLARE, a market-town of Suffolk, 13 miles south of Bury. E. Long. 35°. N. Lat. 52. 15. It gives the title of Earl to the duke of Newcastle.

CLARE is also the capital of a county of the same name in the province of Connaught, in Ireland, situated about 17 miles north-west of Limerick. W. Long. 9. o. N. Lat. 52. 40.

CLARENCEUX, the second king at arms, so called from the duke of Clarence, to whom he first belonged: for Lionel, 3^d son to Edward III. having by his wife the honour of Clare in the county of Thomond, was afterwards declared duke of Clarence; which dukedom afterwards escheated to Edward IV. he made this earl a king at arms. His office is to marshal and dispose of the funerals of all the lower nobility, as baronets, knights, esquires, on the south side of the Trent; whence he is sometimes called *surroy* or *south-roy*, in contradistinction to *norroy*.

CLARENDON (Constitutions of), certain constitutions made in the reign of Henry II. A.D. 1164, in a parliament held at Clarendon; whereby the king checked the power of the Pope and his clergy, and greatly narrowed the total exemption they claimed from secular jurisdiction.

CLARENDON (Earl of). See HYDE.

CLARENZA, the capital of a duchy of the same name in the Morea; it is a sea-port town, situated on the Mediterranean. E. Long. 21. 40. N. Lat. 37. 40.

CLARET, a name given by the French to such of their red wines as are not of a deep or high colour. See WINE.

CLARICHORD, or MANICHORD, a musical instrument in form of a spinnet.

It has 49 or 50 stops, and 70 strings, which bear

on five bridges, the first whereof is the highest, the rest diminishing in proportion. Some of the strings are in unison, their number being greater than that of the stops. There are several little mottoes for passing the jacks, armed with brafs-hooks, which stop and raise the chords instead of the feather used in virginals and spinnets: but what distinguishes it most is, that the chords are covered with pieces of cloth, which render the sound sweeter, and deaden it so that it cannot be heard at any considerable distance: whence it comes to be particularly in use among the nuns, who learn to play, and are unwilling to disturb the silence of the dormitory.

CLARIFICATION, the act of cleaning or fining any fluid from all heterogeneous matter or feculencies.

The substances usually employed for clarifying liquors, are whites of eggs, blood, and isinglass. The two first are used for such liquors as are clarified whilst boiling hot; the last for those which are clarified in the cold, such as wines, &c. The whites of eggs are beat up into a froth, and mixed with the liquor, upon which they unite with and entangle the impure matters that floated in it; and presently growing hard, by the heat, carry them up to the surface in form of a scum no longer dissoluble in the liquid. Blood operates in the same manner, and is chiefly used in purifying the brine from which salt is made. Great quantities of isinglass are consumed for fining turbid wines. For this purpose some throw an entire piece, about a quarter of an ounce, into a wine cask; by degrees the glue dissolves, and forms a skin upon the surface, which at length subsiding, carries down with it the feculent matter which floated in the wine. Others previously dissolve the isinglass; and having boiled it down to a slimy consistence, mix it with the liquor, roll the cask strongly about, and then suffer it to stand to settle. Neuman questions the wholesomeness of wines thus purified; and assures us that he himself, after drinking only a few ounces of sack thus clarified, but not settled quite fine, was seized with sickness and vomiting, followed by such a vertigo that he could not stand upright for a minute together. The giddiness continued with a nausea and want of appetite for several days.

CLARIGATIO, in Roman antiquity, a ceremony that always preceded a formal declaration of war. It was performed in this manner: first four heralds crowned with vervain, were sent to demand satisfaction for the injuries done the Roman state. These heralds taking the gods to witness that their demands were just, one of them, with a clear voice, demanded restitution within a limited time, commonly 33 days; which being expired without restitution made, then the *pater patratus*, or prince of the heralds, proceeded to the enemies frontiers, and declared war.

CLARION, a kind of trumpet, whose tube is narrower and its tone acuter and shriller than that of the common trumpet. It is said that the clarion, now used among the Moors and Portuguese, who borrowed it from the Moors, served anciently for a treble to several trumpets, which sounded tenor and bass.

CLARISSES, an order of nuns so called from their

Clarification
Clarifies.

Clarke. founder St Clara. She was in the town of Affisa in Italy; and having renounced the world to dedicate herself to religion, gave birth to this order in the year 1212; which comprehends not only these nuns that follow the rule of St Francis, according to the strict letter, and without any mitigation, but those likewise who follow the same rule softened and mitigated by several popes. It is at present one of the most flourishing orders of nuns in Europe. After Ferdinand Cortez had conquered Mexico for the king of Spain, Isabella of Portugal, wife of the emperor Charles V. sent thither some nuns of the order of St Clara, who made several settlements there. Near their monasteries were founded communities of Indian young women, to be instructed by the clarisses in religion, and such works as were suitable to persons of their sex. These communities are so considerable that they usually consist of four or five hundred.

CLARKE (Samuel) D. D. a preacher and writer of considerable note in the reign of Charles II. was, during the inter-regnum, and at the time of the ejection, minister of St Bennet Fink in London. In November 1660, he, in the name of the Presbyterian ministers, presented an address of thanks to the king for his declaration of liberty of conscience. He was one of the commissioners of the Savoy; and behaved on that occasion, with great prudence and moderation. He sometimes attended the church as an hearer and communicant; and was much esteemed by all that knew him, for his great probity and industry. The most valuable of his numerous works are said to be his *Lives of the Puritan Divines* and other persons of note, 22 of which are printed in his *martryology*: the rest are in his *Lives of Eminent Persons* in this latter Age, folio; and in his *Marrow of Ecclesiastical History*, in folio and quarto. He died in 1680.

CLARKE (Samuel), the son of the former, was fellow of Pembroke-hall, in Cambridge; but was ejected from his fellowship for refusing to take the engagements, as he was also afterwards from his rectory of Grendon, in Buckinghamshire. He applied himself early to the study of the Scriptures; and his annotations on the Bible, printed together with the sacred text, is highly commended by Dr Owen, Mr Baxter, and Dr Calamy. He died in 1701, aged 75.

CLARKE (Dr Samuel), was born in the city of Norwich in 1675. His father was an alderman of that city, and one of the representatives of it in parliament for several years. In 1691, he went to Caius-college Cambridge; where, though the Cartesian philosophy then prevailed, he soon made himself master of the Newtonian system; and in order to his first degree, surprised the whole audience by the accuracy with which he traced a question in it. In 1697, he published a Latin translation of Rohault's physics, with annotations. After this he turned his thoughts to divinity; and met with a favourable opportunity; being, in 1699, appointed chaplain to Dr John Moore, then bishop of Norwich, who treated him with all the marks of the highest esteem. In 1701, he published his paraphrase upon the gospel of St Matthew, which was followed by the paraphrases on St Mark and St Luke, and soon after on St John, so universally admired. He intended to have gone through all the re-

maining books of the New Testament, but was diverted from it. In 1704 and 1705, he preached, and soon after published, 16 sermons at Boyle's lecture, so justly admired. In 1706, he published his letter to Mr Dodwell, concerning the immortality of the soul; which was soon followed by four defenses of it, and the Answer to Toland's *Amyntor* added to them. The same year he translated Sir Isaac Newton's optics into Latin. Queen Anne, to whose favour his own merits recommended him, upon the vacancy of St James's, Westminster, presented him with that rectory. Upon this advancement he took his degree of doctor of divinity in the university of Cambridge; on which occasion his public exercise was prodigiously applauded. In 1712, he published a splendid edition of Caesar's Commentaries, dedicated to the duke of Marlborough; and the same year appeared his Scripture Doctrine of the Trinity, which gave occasion to a great number of books upon that subject by himself as well as others, and was complained of by the lower house of convocation: but the upper house declared themselves satisfied with his explanations upon the subject of the complaint. In 1715, he had a dispute with Mr Leibnitz relating to some principles of natural philosophy and religion; and the papers that passed between them were published at London in 1717. His alterations in the forms of Doxology occasioned a considerable controversy. In 1724, he published 17 sermons; and, the year following, his "Discourse concerning the connection of the Prophecies in the Old Testament, and the application of them in the New to Christ," in answer to a famous book of Mr Collins, intitled "Grounds and reasons of the Christian Religion." Upon the death of Sir Isaac Newton, he was offered by the court the place of master of the mint, worth L. 1500 a-year, which he refused. In 1728, he wrote a letter to Mr Benjamin Hoadley, F. R. S. occasioned by the controversy relating to the proportion of velocity and force of bodies in motion; and in the beginning of the year following, he published at London, in 4to, twelve books of Homer's Iliad, with the Latin version, accurately corrected, and learned notes, dedicated to the duke of Cumberland. He died in 1729; and since his death there have been published his exposition of the church-catechism, and 10 volumes of his sermons. He was a man of deep penetration; a sincere lover of truth; profoundly acquainted with the abstrusest speculations; and an amiable example of the temper, studies, and practice, becoming a Christian divine.

CLARO-OBSCURO, or **CLAIR-OBSCURE**, in painting, the art of distributing to advantage the lights and shadows of a piece, both with respect to the easing of the eye, and the effect of the whole piece.

CLARO-Obscuro, or **Chiaro-scuro**, is also used to signify a design consisting only of two colours, most usually black and white, but sometimes black and yellow; or it is a design washed only with one colour, the shadows being of a dusky brown, and the lights heightened up by white.

The word is also applied to prints of two colours taken off at twice: whereof there are volumes in the cabinets of those who are curious in prints.

CLARY, in botany. See **SALVIA**.

CLARY-

Clarke
Clary.

Clary
Clavaria.

CLARY-*Water*, a spirit drawn from an infusion of the herb clary in spirit of wine; being a very pleasant and excellent cordial.

CLASMIUM, in natural history, the name of a genus of fossils, of the class of the gypsums; the characters of which are, that they are of a soft texture, and of a dull opaque look, being composed, as all the other gypsums, of irregularly arranged flat particles.

The word is derived from the Greek *κλασμός*, a fragment or small particle; from the flaky small particles of which these bodies are composed: of this genus there is only one known species: this is of a tolerably regular and even structure; though very coarse and harsh to the touch. It is of a very lively and beautiful red in colour; and is found in thick roundish masses, which, when broken, are to be seen composed of irregular arrangements of flat particles; and emulate a striated texture. It will neither give fire with steel, nor ferment with acids; but calcines very freely and easily, and affords a very valuable plaster of Paris, as do all the purer gypsums. It is common in Italy, and is greatly esteemed there; it is also found in some parts of England, particularly Derbyshire, but there is not much regarded.

CLASPERS, or TENDRILS. See CIRRHUS.

CLASS, an appellation given to the most general subdivisions of any thing: thus, *animal* is subdivided into the classes quadrupeds, birds, fishes, &c. which are again subdivided into serieses or orders; and these last into genera. See BOTANY, and ZOOLOGY.

CLASS, is also used in schools, in a synonymous sense with *form*, for a number of boys all learning the same thing.

CLASSIC, or CLASSICAL, an epithet, chiefly applied to authors read in the classes at schools.

This term seems to owe its origin to Tullius Servius, who, in order to make an estimate of every person's estate, divided the Roman people into six bands, which he called *classes*. The estate of the first class was not to be under 200l. and these by way of eminence were called *classici*, classics: hence authors of the first rank came to be called classics, all the rest being said to be *infra classem*: thus Aristotle is a classic author in philosophy; Aquinas, in school-divinity, &c.

CLATHRI, in antiquity, bars of wood or iron, used in securing doors and windows. There was a goddess called *Clathra*, that presided over the clathri.

CLAVARIA, CLUB-TOP; a genus of the order of the fungi, belonging to the cryptogamia class of plants. There are 16 species, of which none are remarkable except the hemotades, or oak-leather club-top. This exactly resembles tanned leather, except that it is thinner and softer. It is of no determinate form. It grows in the clefts and hollows of old oaks, and sometimes on ash in Ireland and in some places of England, &c. In Ireland it is used to dress ulcers, and in Virginia to spread plaisters upon, instead of leather.

A modern writer on natural history, (Mr Miller), has asserted the whole genus of clavaria to belong to the tribe of *zoophytes*, that is, to the animal, and not to the vegetable kingdom. According to his method, he ranks them among the Vermes, under a subdivision which he terms *Fungosa osculis atomiferis*; thereby un-

derstanding them to be compound animals with many orifices on their surface, from which are protruded atoms or animalcules which have a visible spontaneous motion, something similar to what is now acknowledged to be a fact with regard to a numerous class of marine bodies termed *corallines*. This motion, however, has not been observed by other naturalists. Schæffer has figured the seeds of several clavaria: as they appeared to him through the microscope; and none of these fungi when burnt, emit the strong disagreeable smell peculiar to animal substances.

CLAVARIUM, in antiquity, an allowance the Roman soldiers had for furnishing nails to secure their shoes with. They raised frequent mutinies, demanding largesses of the emperors under this pretence.

CLAVATA VESTIMENTA, in antiquity, habits adorned with purple clavi, which were either broad or narrow. See CLAVUS.

CLAUBERGE (John), a learned professor of philosophy and divinity at Duisburg, was born at Solingen in 1622. He travelled into Holland, France, and England, and in each country obtained the esteem of the learned. The elector of Brandenburg gave him public testimonies of his esteem. He died in 1665. His works were printed at Amsterdam in 2 vols 4to. The most celebrated of these is his treatise intitled *Logica vetus et nova*, &c.

CLAUDE of LORRAIN, a celebrated landscape painter, and a striking example of the efficacy of industry to supply, or at least to call forth, genius. Claude was born in 1600; and being dull and heavy at school, was put apprentice to a pastry-cook: he afterwards rambled to Rome to seek a livelihood; but being very ill-bred, and unacquainted with the language, no body cared to employ him. Chance threw him at last in the way of Augustino Trassio, who hired him to grind his colours, and to do all his household drudgery, as he kept no other servant. Here his soul enlarged apace, under the instructions of his master, who hoped to extend the abilities of his service; and he would at length continue whole days on the banks of the Tiber, and in the open fields, deriving his lessons from nature alone. He was as much admired for his performances in fresco as in oil; and was often employed by pope Urban VIII. and many of the Italian princes, in adorning their palaces, till his death in 1682.

CLAUDE (John), a Protestant divine, born in the province of Angoumois in 1619. Mess. de Port Royal using their utmost endeavours to convert M. de Turenne to the catholic faith, presented him with a piece calculated to that end, which his lady engaged Mr Claude to answer; and his performance gave rise to the most famous controversy that was ever carried on in France between the Roman Catholics and Protestants. On the revocation of the edict of Nantz, he retired to Holland, where he met with a kind reception, and was honoured with a considerable pension by the prince of Orange. He died in 1687; and left a son Isaac Claude, whom he lived to see minister of the Walloon church at the Hague, and who published several excellent works of his deceased father.

CLAUDIA, a vestal virgin at Rome, who, being suspected of unchastity, is said to have been cleared from

Clavarium
Claudia.

Claudianus
|
Clavus.

from that imputation in the following manner: the image of Cybele being brought out of Phrygia to Rome in a barge, and it happening to tickle so fast in the river Tyber that it could not be moved, she tying her girdle, the badge of chastity, to the barge, drew it along to the city, which a thousand men were unable to do.

CLAUDIUS (Claudius), a Latin poet, flourished in the 4th century, under the emperor Theodosius, and under his sons Arcadius and Honorius. It is not agreed of what country he was a native; but he came to Rome in the year of Christ 395, when he was about 30 years old; and there insinuated himself into Stilicho's favour; who being a person of great abilities both for civil and military affairs, though a Goth by birth, was so considerable a person under Honorius, that he may be said for many years to have governed the western empire. Stilicho afterwards fell into disgrace, and was put to death; and it is more than probable that the poet was involved in the misfortunes of his patron, and severely persecuted in his person and fortunes by Hadrian, an Egyptian by birth, who was captain of the guards to Honorius, and succeeded Stilicho. There is reason, however, to think that he rose afterwards to great favour; and obtained several honours both civil and military. The princess Serena had a great esteem for Claudian, and recommended and married him to a lady of great quality and fortune in Libya. There are a few little poems on sacred subjects, which through mistake have been ascribed by some critics to Claudian; and so have made him be thought a Christian. But St. Austin, who was cotemporary with him, expressly says, that he was a Heathen. The time of Claudian's death is uncertain, nor do we know any further particulars of his life than what are to be collected from his works, and which we have already related above. He is thought to have more of Virgil in his style than all the other imitators of him.

CLAUDIUS I. Roman emperor, *A. D.* 41. The beginning of his reign was very promising; but it was soon discovered that little better than an idiot filled the throne, who might easily be made a tyrant: accordingly he became a very cruel one, through the influence of his empress, the infamous Messalina: after her death, he married his niece Agrippina, who caused him to be poisoned to make way for Nero, *A. D.* 54. See (*History of*) *Rome*.

CLAUDIUS II. (Aurelius) surnamed *Gothicus*, signified himself by his courage and prudence under the reigns of Valerian and Julian; and on the death of the latter was declared emperor in 268. He put to death Aureolus, the murderer of Galienus; defeated the Germans; and in 269 marched against the Goths, who ravaged the empire with an army of 300,000 men, which he at first harried, and the next year entirely defeated: but a contagious disease, which had spread through that vast army, was caught by the Romans; and the emperor himself died of it a short time after, aged fifty-six. Pollio says that this prince had the moderation of Augustus, the virtue of Trajan, and the piety of Antoninus.

CLAVES INSULE, a term used in the Isle of May; where all weighty and ambiguous causes are referred to a jury of twelve, who are called *claves insule*, the keys of the island.

Clavichord
|
Clavus.

CLAVICHORD, and **CLAVICITHERIUM**, two musical instruments used in the 16th century. They were of the nature of the spinnet, but of an oblong figure. The first is still used by the nuns in convents; and that the practitioners may not disturb the sisters in the dormitory, the strings are muffled with small bits of fine woollen cloth.

CLAVICLE. See *ANATOMY*, n^o 45.

CLAVICYMBALUM, in antiquity, a musical instrument with 30 strings. Modern writers apply the name to our harpichords.

CLAVI VESTIUM, were flowers or studs of purple interwoven with or sewed upon the garments of knights or senators; only, for distinction, the former used them narrow, the latter broad.

CLAVIS properly signifies a **KEY**; and is sometimes used in English to denote an explanation of some obscure passages of any book or writing.

CLAVIUS (Christopher), a German Jesuit born at Bamberg, excelled in the knowledge of the mathematics, and was one of the chief persons employed to rectify the calendar; the defence of which he also undertook against those who censured it, especially Scaliger. He died at Rome in 1612, aged 75. His works have been printed in five volumes folio; the principal of which is his commentary on Euclid's elements.

CLAUSE, in grammar, denotes a member of a period or sentence.

CLAUSE signifies also an article or particular stipulation in a contract, a charge or condition in a testament, &c.

CLAUSENBURG, a large city of Transylvania, situated on the river Samos, in E. Long. 20. 50. N. Lat. 47. 10.

CLAVUS, in antiquity, an ornament upon the robes of the Roman senators and knights; which was more or less broad, according to the dignity of the person: hence the distinction of *tunica augusti-clavia* and *lati-clavia*.

CLAVUS, in medicine and surgery, is used in several significations: 1. *Clavus hytericus*, is a shooting pain in the head, between the pericranium and cranium, which affects such as have the green-sickness. 2. *Clavus oculorum*, according to Celsus, is a callous tubercle on the white of the eye, taking its denomination from its figure. 3. *Clavus* imports indurated tubercles of the uterus. 4. It also imports a surgical instrument of gold, mentioned by Amatus Lusitanus, designed to be introduced into an excruciated palate, for the better articulation of the voice. And, 5. It signifies a callus, or corn on the foot.

CLAVUS Annalis, in antiquity. So rude and ignorant were the Romans towards the rise of their state, that the driving or fixing a nail was the only method they had of keeping a register of time; for which reason it was called *clavus annalis*. There was an ancient law, ordaining the chief prætor to fix a nail every year on the Ides of September; it was driven into the right side of the temple of Jupiter Opt. Max. towards Minerva's temple. This custom of keeping an account of time by means of fixing nails, was not peculiar to the Romans; for the Etrurians used likewise

wife to drive nails into the temple of their goddess Nortia with the same view.

CLAW, among zoologists, denotes the sharp-pointed nails with which the feet of certain quadrupeds and birds are furnished.

Crab's CLAWS, in pharmacy. See *Crab's Claws*.

CLAY, in natural history, a genus of earths, the characters of which are these: They are firmly coherent, weighty, and compact; stiff, viscid, and ductile to a great degree, while moist; smooth to the touch; not easily breaking between the fingers, nor readily diffusible in water; and, when mixed, not readily subdividing from it. See *CHEMISTRY*, n° 35.

Clay shrinks remarkably when drying; in so much that Dr Lewis observes, the purity of it may be known by the degree to which it shrinks. He made experiments on it when pure, and when mixed with various proportions of sand. Pure clay he found shrank one part in 18 while drying; but, when mixed with twice its weight of sand, only one part in 30.

CLAY, a town of Norfolk in England, seated on an arm of the sea between two rivers, in E. Long. o. 30. N. Lat. 47. 28.

CLAY-Lands, those abounding with clay, whether black, blue, yellow, *&c.* of which the black and the yellow are the best for corn.

All clay-foils are apt to chill the plants growing on them in moist seasons, as they retain too much water; in dry seasons, on the contrary, they turn hard and choke the plants. Their natural produce is weeds, goose-grass, large daisies, thistles, docks, poppies, *&c.* Some clay-foils will bear clover and rye-grass; and, if well manured, will produce the best grain: they hold manure the best of all lands; and the most proper for them are horse-dung, pigeon's dung, some kinds of marle, folding of sheep, malt-dust, ashes, chalk, lime, foot, *&c.*

CLAYTONIA, in botany; a genus of the monogynia order, belonging to the pentandria class of plants. There are two species, natives of America. They are very low herbaceous plants, with white flowers; and are possessed of no remarkable property.

CLEANTHES, a stoic philosopher, disciple of Zeno, flourished 240 years before Christ. He maintained himself in the day, by working in the night: being questioned by the magistrates how he subsisted, he brought a woman for whom he kneaded bread, and a gardener for whom he drew water; and refused a present from them. He composed several works, of which there are now only a few fragments remaining.

CLEAR, as a naval term, is variously applied to the weather, the sea-coasts, cordage, navigation, *&c.* The weather is said to be clear when it is fair and open, as opposed to cloudy or foggy. The sea-coast is called clear when the navigation is not interrupted, or rendered dangerous by rocks, sands, or breakers, *&c.* It is expressed of cordage, cables, *&c.* when they are unembarrassed, or disentangled, so as to be ready for immediate service. It is usually opposed to *foul*, in all these senses.

CLEATS, in naval affairs, pieces of wood, having one or two projecting ends whereby to fasten the

ropes: some of them are fastened to the shrouds below for this purpose, and others nailed to different places of the ship's deck or sides.

CLÈCHE, in heraldry, a kind of cross, charged with another cross of the same figure, but of the colour of the field.

CLEDGE, among miners, denotes the upper stratum of fuller's earth.

CLEF, or **CLIFF**, in music, derived from the Latin word *clavis*, a key; because by it is expressed the fundamental found in the diatonic scale, which requires a determin'd succession of tones or semitones, whether major or minor, peculiar to the note from whence we set out, and resulting from its position in the scale. Hence, as it opens a way to this succession, and discovers it, the technical term *key* is used with great propriety. But clefs rather point out the position of different musical parts in the general system, and the relations which they bear one to another.

A clef, says Rousseau, is a character in music placed at the beginning of a stave, to determine the degree of elevation occupied by that stave in the general claviary or system, and to paint out the names of all the notes which it contains in the line of that clef.

Anciently the letters by which the notes of the gammut had been signified were called *clefs*. Thus the letter A was the clef of the note *la*, C the clef of *ut*, E the clef of *mi*, &c. In proportion as the system was extended, the embarrassment and superfluity of this multitude of clefs were felt.

Gui d'Arezzo who had inverted them, marked a letter or clef at the beginning of each line in the stave; for as yet he had placed no notes in the spaces. In process of time they marked no more than one of the seven clefs at the beginning of one of the lines only; and this was sufficient to fix the position of all the rest, according to their natural order: at last, of these seven lines or clefs, they selected four, which were called *claves signatæ*, or *discriminating clefs*; because they satisfied themselves with marking one of them upon one of the lines, from which the powers of all the others might be recognized. Presently afterwards they even retrenched one of these four, *viz.* the gamma, of which they made use to mark the *sol* below, that is to say, the hypoproslambanomenon added to the system of the Greeks.

In reality Kircher asserts, that if we understood the characters in which ancient music was written, and examined minutely the forms of our clefs, we should find that each of them represent the letter a little altered in its form, by which the note was originally named. Thus the clef of *sol* was originally a G, the clef of *ut* a C, and the clef of *fa* an F.

We have then three clefs, one a fifth above the other. The clef of F, or *fa*, which is the lowest; the clef of *ut*, or C, which is a fifth above the former; and the clef of *sol*, or G, which is a fifth above that of *ut*. These clefs, both as marked by foreigners and in Britain, may be seen in art. 170. of Music; upon which it is necessary to remark, that, by a remain of ancient practice, the clef is always placed upon a line, and never in a space. It deserves notice, that the clef of *fa* is marked in three different

Clef. rent manners: one in music which is printed; another in music which is written or engraven; and a third in the full harmony of the chorus. See plate LXXXII. fig. 10.

By adding four lines above the clef of *sol*, and three lines beneath the clef of *fa*, which gives both above and below the greatest extent of permanent or established lines, it appears, that the whole scale of notes which can be placed upon the gradations relative to these clefs amounts to 24; that is to say, three octaves and a fourth from the *F*, or *fa*, which is found beneath the first line, to the *si*, or *B*, which is found above the last, and all this together forms what we call the *general claviary*; from whence we may judge, that this compass has, for a long time, constituted the extent of the system. But as at present it is continually acquiring new degrees, as well above as below, the degrees are marked by leger lines, which are added above or below as occasion requires.

Instead of joining all the lines, as has been done by Rousseau in his Dictionary, (plate A, fig. 5.) to mark the relation which one clef bears to another, they separate them five by five; because it is pretty nearly within the degrees to which the compass of ordinary voices extends. This collection of five lines is called a *stave*; and in these they place a clef, to determine the names of the notes, the positions of semitones, and to shew what station the stave occupies in the claviary or general scale.

In whatever manner we take five successive lines in the claviary, we shall find one clef comprehended; nay, sometimes two; in which case one may be retrenched as useless. Custom has even prescribed which of the two should be retrenched, and which retained; it is this likewise which has determined the number of positions assigned to each clef.

If I form a stave of the first five lines in the claviary, beginning from below, I find the clef of *fa* in the fourth line. This then is one position of the clef, and this position evidently relates to the lowest note; thus likewise it is that of the bass clef.

If I wish to gain a third in ascent, I must add a line above; I must then obliterate one below, otherwise the stave will contain more than five lines. The clef of *fa* then is found transferred from the fourth to the third, and the clef of *ut* is likewise found upon the fifth; but as two clefs are useless, they retrench here that of *ut*. It is evident, that the stave of this clef is a third higher than the former.

By throwing away still one line below to gain another above, we have a third kind of stave, where the clef of *fa* will be found upon the second line, and that of *ut* upon the fourth. Here we leave out the clef of *fa*, and retain that of *ut*. We have now gained another third above, and lost it below.

By continuing these alterations from line to line, we pass successively thro' four different positions of the clef of *ut*. Having arrived at that of *sol*, we find it placed upon the second line, and then upon the first. This position includes the five highest lines, and gives the sharpest diapason which the clefs can signify.

The reader may see in Rousseau's Musical Dictionary, Plate A. fig. 5. this succession of clefs from the

lowest to the highest; which in all constitutes eight staves, clefs, or different positions of clefs.

Whatever may be the character and genius of any voice or instrument, if its extent above or below does not surpass that of the general claviary, in this number may be found a station and a clef suitable to it; and there are, in reality, clefs determined for all the parts in music. If the extent of a part is very considerable, so that the number of lines necessary to be added above or below may become inconvenient, the clef is then changed in the course of the music. It may be plainly perceived by the figure, what clef it is necessary to change, for raising or depressing any part, under whatever clef it may be actually placed.

It will likewise appear, that in order to adjust one clef to another, both must be compared by the general claviary, by means of which we may determine, what every note under one of the clefs is with respect to the other. It is by this exercise repeated that we acquire the habit of reading with ease all the parts.

From this manœuvre it follows, that we may place whatever note we please of the gammut upon any line or space whatever of the stave, since we have the choice of eight different positions, which is equal to the number of notes in the octave. Thus you may mark a whole tune upon the same line, by changing the clef at each gradation. The 7th fig. of the same plate in Rousseau's Musical Dictionary, to which we formerly referred, shews by the series of clefs the order of the notes, *re, fa, la, ut, mi, sol, si, re*, rising by thirds, although all placed upon the same line. The fig. following represents upon the order of the same clefs the note *ut*, which appears to descend by thirds upon all the lines of the stave; and further, which yet, by means of changing the clef, still preserves its unison. It is upon such examples as this, that scholars ought to exercise themselves, in order to understand at the first glance the powers of all the clefs, and their simultaneous effect.

There are two of their positions, *viz.* the clef of *sol* upon the first line, and that of *fa* upon the third, which seem daily to fall more and more into disuse. The first of these may seem less necessary, because it produces nothing but a position entirely similar to that of *fa* upon the fourth line, from which however it differs by two octaves. As to the clef of *fa*, it is plain, that in removing it entirely from the third line, we shall no longer have any equivalent position, and that the composition of the claviary, which is at present complete, will by these means become defective.

This much for Rousseau's account of clefs. He proceeds to explain their transposition; but as this would render the present article too long and intricate, we remit the curious to his *Musical Dictionary*, vol. 1. page 162. See also Malcom's *Dissertation on Music*.

CLEFT, in a general sense, is a space made by the separation of parts. Green timber is very apt to split and cleave in several places, after it is wrought into form; and these cracks in it are very disagreeable to the sight. The common method of the country carpenters is to fill up these cracks with a mixture of greafe and saw-dust; but the neatest way of all is, the

the foaking both sides well with the fat of beef-broth, and then dipping pieces of sponge into the same broth, and filling up all the cracks with them: they swell out so as to fill the whole crack; and accommodate themselves so well to it, that the deficiency is hardly seen.

CLEFTS, or *Cracks*, in farriery, appear on the bough of the palsterns, and are caused by a sharp and malignant humour. See FARRIERY, sect. xxxiii.

CLEMA, in antiquity, a twig of the vine, which served as a badge of the Centurion's office.

CLEMATIS, VIRGIN'S-BOWER; a genus of the polygynia order, belonging to the polyandria class of plants. There are twelve species, all of which, except two, are shrubby, climbing plants, very hardy, and adorned with quadrupetalous flowers of red, blue, purple, white, and greenish flowers. They are very easily propagated by layers or cuttings. The *vitis alba*, one of the species, is very acrid to the taste, and without any smell. It is frequently used as a caustic, and for cleansing old ulcers. The root is said to be purgative. The leaves of all the species bruised and applied to the skin, burn it into carbuncles as in the plague; and if applied to the nostrils in a sultry day immediately after being cropped, will cause the same uneasy sensation as a flame applied to that part would occasion. Hence the title of *flammula*, or "little flame," by which this genus of plants was formerly distinguished.

CLEMENS ROMANUS, bishop of Rome, where he is said to have been born; and to have been fellow labourer with St Peter and St Paul. We have nothing remaining of his works that is clearly genuine, excepting one epistle, written to quiet some disturbances in the church of Corinth; which, next to holy writ, is esteemed one of the most valuable remains of ecclesiastical antiquity.

CLEMENS *Alexandrinus*, so called to distinguish him from the former; was an eminent father of the church, who flourished at the end of the second and beginning of the third centuries. He was the scholar of Pantænus, and the instructor of Origen. The best edition of his works is that in 2 vols folio, published in 1715, by archbishop Potter.

CLEMENT V. (pope), the first who made a public sale of indulgences. He transplanted the holy see to Avignon in France; greatly contributed to the suppression of the knights templars; and was author of a compilation of the decrees of the general councils of Vienna, styled *Clementines*. He died in 1314.

CLEMENT VII. (Julius de Medicis), pope, memorable for his refusing to divorce Catharine of Arragon from Henry VIII.; and for the bull he published upon the king's marriage with Anne Boleyn; which, according to the Romish authors, lost him England. He died in 1534.

CLEMENT XIV. (Francis Laurentius Ganganelli), the late pope, was born at St Angelo in the duchy of Urbino, in October 1705; and chosen pope, though not yet a bishop, in 1769: at which time the see of Rome was involved in a most disagreeable and dangerous contest with the house of Bourbon. His reign was rendered troublesome by the collision of parties on the affairs of the Jesuits; and it is pretended that

his latter days were embittered by the apprehensions of poison. Though this report was probably apocryphal, it is said that he often complained of the heavy burden which he was obliged to bear; and regretted, with great sensibility, the loss of that tranquillity which he enjoyed in his retirement when only a simple Franciscan. He was, however, fortunate in having an opportunity, by a single act, to distinguish a short administration of five years in such a manner as will ever prevent its sinking into obscurity. His death was immediately attributed to poison, as if an old man of 70, loaded with infirmities and disorders, could not quit the world without violence. His proceedings against the Jesuits furnished a plausible pretence for this charge; and the malevolence of their enemies embellished it with circumstances. It even seems as if the ministers of those powers who had procured their dissolution did not think it beneath them to countenance the report; as if falsehood was necessary to prevent the revival of a body which had already sunk in its full strength, under the weight of real misconduct. The charge was the more ridiculous, as the Pontiff had undergone a long and painful illness, which originally proceeded from a suppression of urine, to which he was subject; yet the report was propagated with the greatest industry: and though the French and Spanish ministers were present at the opening of his body, the most horrible circumstances were published relative to that operation. It was confidently told that the head fell off from the body, and that the stench poisoned and killed the operators. It availed but little that the operators shewed themselves alive and in good health, and that the surgeons and physicians proved the falsehood of every part of the report. Clement XIV. appears to have been a man of a virtuous character, and possessed of considerable abilities. He died much regretted by his subjects.

CLENARD (Nicholas), a celebrated grammarian in the 16th century, was born at Dieff; and after having taught humanity at Louvain, travelled into France, Spain, Portugal, and Africa. He wrote in Latin, 1. Letters relating to his Travels, which are very curious and scarce. 2. A Greek Grammar, which has been revised and corrected by many grammarians; and other works. He died at Grenoble, in 1542.

CLEOBULUS, son of Evagoras, and one of the Grecian sages; he was valiant, a lover of learning, and an enemy to vice. Flourished about 560 years before Christ.

CLEOME, in botany, a genus of the filiquosa order, belonging to the tetradynamia class of plants. There are 15 species; all of them, except two, natives of warm climates. They are herbaceous plants rising from one to two feet high; and are adorned with flowers of various colours, as red, yellow, flesh colour, &c. They are propagated by seeds, and require no other care than what is common to other exotics which are natives of warm countries.

CLEOMENES, the name of three Lacedæmonian kings. See LACEDÆMON.

CLEOPATRA, the celebrated queen of Egypt, was daughter of Ptolemy Auletes. By her extraordinary beauty, she subdued the two renowned Roman

Cleostratus
Clepsydra.

generals Julius Cæsar and Marc Antony: the latter of whom, it is thought, lost the empire of Rome by his attachment to her. At length, Marc Antony being subdued by Octavius Cæsar, he tried the force of her declining charms upon the conqueror, but in vain; upon which, expecting no mercy from him, she poisoned herself, 30 years before Christ. According to some authors, she was the restorer of the Alexandrian library, to which she added that of Pergamos; and it is said, that she studied philosophy, to console her for the absence of Antony. With her death ended the family of the Ptolemies in Egypt, after it had reigned from the death of Alexander 294 years: for Egypt, after this, was reduced to a Roman province; in which dependence it remained, till it was taken from them by the Saracens, *A. D. 641*.

CLEOSTRATUS, a celebrated astronomer born at Tenedos, was, according to Pliny, the first who discovered the signs of the Zodiac; others say, that he only discovered the signs Aries and Sagittarius. He also corrected the errors of the Grecian year about the 306th before Christ.

CLEPSYDRA, an instrument or machine serving to measure time by the fall of a certain quantity of water.

The word comes from *κλεψύδρα, κενδο, ἰδρυ, aqua*, water; though there have likewise been clepsydræ made with mercury.

The Egyptians, by this machine, measured the course of the sun. Tycho Brahe, in our days, made use of it to measure the motion of the stars, &c. and Dredley used the same contrivance in making all his maritime observations. The use of clepsydra is very ancient: they were invented in Egypt under the Ptolemies; as were also sun-dials. Their use was chiefly in the winter; the sun-dials served in the summer. They had two great defects: the one, that the water ran out with a greater or less facility, as the air was more or less dense; the other, that the water ran more readily at the beginning, than towards the conclusion. M. Amontons has invented a clepsydra free from both these inconveniences; and which has these three grand advantages, of serving the ordinary purpose of clocks, of serving in navigation for the discovery of the longitude, and of measuring the motion of the arteries.

Construction of a CLEPSYDRA. To divide any cylindric vessel into parts to be emptied in each division of time; the time wherein the whole, and that wherein any part is to be evacuated, being given.

Suppose, *v. gr.* a cylindric vessel, whole charge of water flows out in twelve hours, were required to be divided into parts to be evacuated each hour. 1. As the part of time 1, is to the whole time 12; so is the same time 12 to a fourth proportional, 144. 2. Divide the altitude of the vessel into 144 equal parts: here the last will fall to the last hour; the three next above to the last part but one; the five next to the tenth hour, &c.; lastly, the 23 last to the first hour. For since the times increase in the series of the natural numbers 1, 2, 3, 4, 5, &c. and the altitudes, if the numeration be in retrograde order from the twelfth hour, increase in the series of the unequal numbers 1, 3, 5, 7, 9, &c. the altitude, computed from the twelfth

hour, will be as the squares of the times 1, 4, 9, 16, 25, &c. therefore the square of the whole time 144, comprehends all the parts of the altitude of the vessel to be evacuated. But a third proportional to 1 and 12 is the square of 12, and consequently it is the number of equal parts into which the altitude is to be divided, to be distributed according to the series of the unequal numbers, through the equal interval of hours. Since in lieu of parts of the same vessel, other less vessels equal thereto may be substituted; the altitude of a vessel emptied in a given space of time being given, the altitude of another vessel to be emptied in a given time may be found; *viz.* by making the altitudes as the squares of the times.

CLERC (John le), a most celebrated writer and universal scholar, born at Geneva in 1657. After he had passed through the usual course of study at Geneva, and had lost his father in 1676, he went to France in 1678; but returning the year after, he was ordained with the general applause of all his examiners. In 1682, le Clerc visited England with a view to learning the language. He preached several times in the French churches in London, and visited several bishops and men of learning; but the smoky air of the town not agreeing with his lungs, he returned to Holland, within the year, where he at length settled. He preached before a synod held at Rotterdam by the remonstrants in 1684; and was admitted professor of Philosophy, polite literature, and the Hebrew tongue, in their school at Amsterdam. The remainder of his life affords nothing but the history of his works, and of the controversies he was engaged in; but these would lead into too extensive a detail. He continued to read regular lectures; and because there was no single author full enough for his purpose, he drew up and published his *Logic*, *Ontology*, *Pneumatology* and *Natural Philosophy*. He published *Art Critica*; a Commentary on the Old Testament; a Compendium of Universal History; an Ecclesiastical History of the two first Centuries; a French Translation of the New Testament, &c. In 1686, he began, jointly with M. de la Croix, his *Bibliothèque Universelle et Historique*, in imitation of other literary journals; which was continued to the year 1693, inclusive, in 26 vols. In 1703, he began his *Bibliothèque Choisie*, and continued it to 1714, and then commenced another work on the same plan called *Bibliothèque ancienne et moderne*, which he continued to the year 1728; all of them justly deemed excellent stores of useful knowledge. In 1728, he was seized with a palsy and fever; and, after spending the last six years of his life with little or no understanding, died in 1736.

CLERC (Sebastian le), engraver and designer in ordinary to the French king, was born at Metz in 1637. After having learnt designing, he applied himself to mathematics, and was engineer to the marshal de la Ferté. He went to Paris in 1665, where he applied himself to designing and engraving with such success, that M. Colbert gave him a pension of 600 crowns. In 1672, he was admitted into the royal academy of painting and sculpture; and in 1680 was made professor of geometry and perspective in the same academy. He published, besides a great number of designs and prints, 1. A Treatise on theoretical and practical

Clerc.

Clergy. practical Geometry, A Treatise on Architecture, and other works; and died in 1714. He was an excellent artist, but chiefly in the petit style. He immortalized Alexander, and Lewis XIV. in miniature. His genius seldom exceeds the dimensions of six inches. Within those limits he could draw up 20,000 men with great dexterity. No artist except Callot and Della Bella, could touch a small figure with so much spirit.

CLERGY, a general name given to the body of ecclesiastics of the Christian church, in contradistinction to the laity. See **LAITY**.

The distinction of Christians into clergy and laity, was derived from the Jewish church, and adopted into the Christian by the apostles themselves: whenever any number of converts was made, as soon as they were capable of being formed into a congregation or church, a bishop or presbyter, with a deacon, were ordained to minister to them. Of the bishops, priests, and deacons, the clergy originally consisted; but in the third century, many inferior orders were appointed, as subservient to the office of deacon, such as **ACOLUTHISTS**, **READERS**, &c.

Black ft. Comment. This venerable body of men being separate and set apart from the rest of the people, in order to attend the more closely to the service of Almighty God, have therefore large privileges allowed them by our municipal laws: and had formerly much greater, which were abridged at the time of the reformation, on account of the ill use which the Popish clergy had endeavoured to make of them. For, the laws having exempted them from almost every personal duty, they attempted a total exemption from every secular tie. But it is observed by Sir Edward Coke, that as the overflowing of waters doth many times make the river to lose its proper channel, so, in times past, ecclesiastical persons, seeking to extend their liberties beyond their due bounds, either lost, or enjoyed not those which of right belonged to them. The personal exemptions do indeed for the most part continue: a clergyman cannot be compelled to serve on a jury, nor to appear at a court-leet, or view of frank-pledge, which almost every other person is obliged to do: but if a layman is summoned on a jury, and before the trial takes orders, he shall notwithstanding appear and be sworn. Neither can he be chosen to any temporal office, as bailiff, reeve, constable, or the like; in regard of his own continual attendance on the sacred function. During his attendance on divine service, he is privileged from arrests in civil suits. In cases also of felony, a clerk in orders shall have the benefit of his clergy, without being branded in the hand; and may likewise have it more than once: in both which particulars he is distinguished from a layman. But, as they have their privileges, so they have also their disabilities, on account of their spiritual vocations. Clergymen are incapable of sitting in the house of commons; and by statute 21 Hen. VIII. c. 13. are not in general allowed to take any lands or tenements to farm, upon pain of 10*l.* per month, and total avoidance of the lease; nor, upon like pain, to keep any tap-house or brew-house; nor shall engage in any manner of trade, nor sell any merchandize, under forfeiture of the treble value. Which prohibition is consonant to the canon law.

Benefit of CLERGY, is an ancient privilege whereby one in orders claimed to be delivered to his ordinary to purge himself of felony.

After trial and conviction* of a criminal, the judgment of the court regularly follows, unless suspended or arrested by some intervening circumstance; of which the principal is *benefit of clergy*: a title of no small curiosity as well as use, and concerning which, therefore, it may not be improper to inquire, 1. Into its original, and the various mutations which this privilege of the clergy has sustained. 2. To what persons it is to be allowed at this day. 3. In what cases. 4. The consequences of allowing it.

I. Clergy, the *privilegium clericale*, or (in common speech) the benefit of clergy, had its original from the pious regard paid by Christian princes to the church in its infant state, and the ill use which the popish ecclesiastics soon made of that pious regard. The exemptions which they granted to the church were principally of two kinds: 1. Exemption of places consecrated to religious duties from criminal arrests; which was the foundation of sanctuaries. 2. Exemption of the persons of clergymen from criminal process before the secular judge in a few particular cases; which was the true original and meaning of the *privilegium clericale*.

But the clergy increasing in wealth, power, honour, number, and interest, soon began to set up for themselves; and that which they obtained by the favour of the civil government, they now claimed as their inherent right, and as a right of the highest nature, indefeasible, and *jure divino*. By their canons, therefore, and constitutions, they endeavoured at, and where they met with easy princes, obtained, a vast extension of those exemptions; as well in regard to the crimes themselves, of which the list became quite universal, as in regard to the persons exempted, among whom were at length comprehended, not only every little subordinate officer belonging to the church or clergy, but even many that were totally laymen.

In England, however, although the usurpations of the pope were very many and grievous, till Henry VIII. totally exterminated his supremacy, yet a total exemption of the clergy from secular jurisdiction could never be thoroughly effected, though often endeavoured by the clergy: and therefore, though the ancient *privilegium clericale* was in some capital cases, yet it was not universally allowed. And in those particular cases, the use was for the bishop or ordinary to demand his clerks to be remitted out of the king's courts as soon as they were indicted: concerning the allowance of which demand there was for many years a great uncertainty: till at length it was finally settled in the reign of Henry VI. that the prisoner should first be arraigned; and might either then claim his benefit of clergy by way of dedynatory plea; or, after conviction, by way of arrest of judgment. This latter way is most usually practised, as it is more to the satisfaction of the court to have the crime previously ascertained by confession or the verdict of a jury; and also it is more advantageous to the prisoner himself, who may possibly be acquitted, and so need not the benefit of his clergy at all.

Clergy.

Originally the law was held that no man should be admitted to the benefit of clergy, but such as had the *habitus et tonsuram clericalem*. But, in process of time, a much wider and more comprehensive criterion was established; every one that could read (a great mark of learning in those days of ignorance and her sister superstition) being accounted a clerk, or *clericus*, and allowed the benefit of clerkship, though neither initiated in clerkship, nor trimmed with the holy tonsure. But when learning, by means of the invention of printing, and other concurrent causes, began to be more generally disseminated than formerly; and reading was no longer a competent proof of clerkship, or being in holy orders; it was found that as many laymen as divines were admitted to the *privilegium clericale*: and therefore by statute 4 Hen. VII. c. 13. a distinction was once more drawn between mere lay scholars, and clerks that were really in orders. And, though it was thought reasonable still to mitigate the severity of the law with regard to the former, yet they were not put upon the same footing with actual clergy; being subjected to a slight degree of punishment, and not allowed to claim the clerical privilege more than once. Accordingly the statute directs, that no person, once admitted to the benefit of clergy shall be admitted thereto a second time, until he produces his orders: and, in order to distinguish their persons, all laymen who are allowed this privilege, shall be burned with a hot-iron in the brawn of the left thumb. This distinction between learned laymen and real clerks in orders was abolished for a time by the statutes 28 Hen. VIII. c. 1. and 32 Hen. VIII. c. 3.; but is held to have been virtually restored by statute 1 Edw. VI. c. 12. which statute also enacts, that lords of parliament and peers of the realm may have the benefit of their peerage, equivalent to that of clergy, for the first offence, (although they cannot read, and without being burnt in the hand), for all offences then clergyable to commoners, and also for the crimes of house-breaking, highway-robbery, horse-stealing, and robbing of churches.

After this burning, the laity, and before it the real clergy, were discharged from the sentence of the law in the king's courts, and delivered over to the ordinary, to be dealt with according to the ecclesiastical canons. Whereupon the ordinary, not satisfied with the proofs adduced in the profane secular court, set himself formally to make a purgation of the offender by a new canonical trial; although he had been previously convicted by his country, or perhaps by his own confession. This trial was held before the bishop in person, or his deputy; and by a jury of twelve clerks: And there, first, the party himself was required to make oath of his own innocence: next, there was to be the oath of twelve compurgators, who swore they believed he spoke the truth: then, witnesses were to be examined upon oath, but on behalf of the prisoner only: and lastly, the jury were to bring in their verdict upon oath, which usually acquitted the prisoner; otherwise, if a clerk, he was degraded, or put to penance. A learned judge in the beginning of last century, remarks with much indignation the vast complication of perjury and subornation of perjury in this solemn farce of a mock trial:

Clergy.

the witnesses, the compurgators, and the jury, being all of them partakers in the guilt: the delinquent party also, though convicted in the clearest manner, and conscious of his own offence, yet was permitted, and almost compelled to swear himself not guilty; nor was the good bishop himself, under whose countenance this scene was transacted, by any means exempt from a share of it. And yet, by this purgation, the party was restored to his credit, his liberty, his lands, and his capacity of purchasing afresh, and was entirely made a new and an innocent man.

This scandalous prostitution of oaths, and the forms of justice, in the almost constant acquittal of felonious clerks by purgation, was the occasion, that, upon very heinous and notorious circumstances of guilt, the temporal courts would not trust the ordinary with the trial of the offender, but delivered over to him the convicted clerk, *abique purgatione faciendo*: in which situation the clerk convicted could not make purgation; but was to continue in prison during life, and was incapable of acquiring any personal property, or receiving the profits of his lands, unless the king should please to pardon him. Both these courses were in some degree exceptionable; the latter perhaps being too rigid, as the former was productive of the most abandoned perjury. As therefore these mock trials took their rise from factious and popish tenets, tending to exempt one part of the nation from the general municipal law; it became high time, when the reformation was thoroughly established, to abolish so vain and impious a ceremony.

Accordingly the statute 18 Eliz. c. 7. enacts, that, for the avoiding such perjuries and abuses, after the offender has been allowed his clergy, he shall not be delivered to the ordinary as formerly; but, upon such allowance, and burning of the hand, he shall forthwith be enlarged and delivered out of prison; with proviso, that the judge may, if he thinks fit, continue the offender in goal for any time not exceeding a year. And thus the law continued unaltered for above a century; except only, that the statute 21 Jac. I. c. 6. allowed, that women convicted of simple larcenies under the value of 10s. should (not properly have the benefit of clergy, for they were not called upon to read; but) be burned in the hand, whipped, or stocked, or imprisoned for any time not exceeding a year. And a similar indulgence by the statutes 3 and 4 W. and M. c. 9. and 4 and 5 W. and M. c. 24. was extended to women guilty of any clergyable felony whatever; who were allowed once to claim the benefit of the statute, in like manner as men might claim the benefit of clergy, and to be discharged upon being burned in the hand, and imprisoned for any time not exceeding a year. All women, all peers, and all male commoners who could read, were therefore discharged in such felonies absolutely, if clerks in orders; and for the first offence upon burning in the hand, if lay; yet all liable, (except peers), if the judge saw occasion, to imprisonment not exceeding a year. And these men who could not read, if under the degree of peerage, were hanged.

Afterwards, indeed, it was considered, that education and learning were no extenuations of guilt, but quite the reverse: and that if the punishment of death

for

Clergy.

for simple felony was too severe for those who had been liberally instructed, it was, *a fortiori*, too severe for the ignorant also. And thereupon, by statute 5 Anne, c. 6. it was enacted that the benefit of clergy should be granted to all those who were entitled to ask it, without requiring them to read by way of conditional merit. And, experience having shewn that so universal a lenity was frequently inconvenient, and an encouragement to commit the lower degrees of felony; and that though capital punishments were too rigorous for these inferior offences, yet no punishment at all, (or next to none, as branding or whipping), was as much too gentle; it was enacted by the same statute 5 Anne, c. 6. that when any person is convicted of any theft or larceny, and burnt in the hand for the same, he shall, at the discretion of the judge, be committed to the house of correction or public work-house, to be there kept to hard labour for any time not less than six months, and not exceeding two years; with a power of inflicting a double confinement in case of the party's escape from the first. And it is also enacted by the statutes 4 Geo. I. c. 11. and 6 Geo. I. c. 23. that when any persons shall be convicted of any larceny, either grand or petit, or any felonious stealing or taking of money or goods and chattels, either from the person or the house of any other, or in any other manner, and who by the law shall be entitled to the benefit of clergy, and liable only to the penalties of burning in the hand, or whipping; the court, in their discretion, instead of such burning in the hand, or whipping, may direct such offenders to be transported to America for seven years; and if they return, or are seen at large in this kingdom within that time, it shall be felony without benefit of clergy.

In this state does the benefit of clergy at present stand; very considerably different from its original institution: the wisdom of the English legislature having, in the course of a long and laborious process, extracted, by a noble alchemy, rich medicines out of poisonous ingredients; and converted, by gradual mutations, what was at first an unreasonable exemption of particular popish ecclesiastics, into a merciful mitigation of the general law with respect to capital punishments.

From the whole of this detail, we may collect, that however, in times of ignorance and superstition, that monster in true policy may for a while subsist, of a body of men residing in a state, and yet independent of its laws; yet when learning and rational religion have a little enlightened mens minds, society can no longer endure an absurdity so gross, as must destroy its very fundamentals. For, by the original contract of government, the price of protection by the united force of individuals, is that of obedience to the united will of the community. This united will is declared in the laws of the land: and that united force is exerted in their due, and universal, execution.

II. We are next to inquire, to what persons the benefit of clergy is to be allowed at this day: and this must chiefly be collected from what has been observed in the preceding article. For, upon the whole, we may pronounce, that all clerks in orders are; without any branding, and of course without any transportation, (for that is only substituted in lieu of the

other,) to be admitted to this privilege, and immediately discharged, or at most only confined for one year; and this as often as they offend. Again, all lords of parliament, and peers of the realm, by the statute 1 Edw. VI. c. 12. shall be discharged in all clergyable and other felonies provided for by the act without any burning in the hand, in the same manner as real clerks convicted: but this is only for the first offence. Lastly, all the commons of the realm, not in orders, whether male or female, shall, for the first offence, be discharged of the punishment of felonies, within the benefit of clergy, upon being burnt in the hand, and suffering discretionary imprisonment; or, in case of larceny, upon being transported for seven years, if the court shall think proper.

III. The third point to be considered is, for what crimes the *privilegium clericale*, or benefit of clergy, is to be allowed. And it is to be observed, that neither in high treason, nor in petit larceny, nor in any mere misdemeanors, it was indulged at the common law: and therefore we may lay it down as a rule, that it was allowable only in petit treason, and capital felonies; which for the most part became legally entitled to this indulgence, by the statute *de clero*, 25 Edw. III. stat. 3. c. 4. which provides, that clerks convicted for treason or felonies, touching other persons than the king himself or his royal majesty, shall have the privilege of holy church. But yet it was not allowed in all cases whatsoever: for in some it was denied even in common law, viz. *insidiatio viarum*, or lying in wait for one on the highway; *depopulation agrorum*, or destroying and ravaging a country; and *combustio domorum*, or arson, that is, burning of houses; all which are a kind of hostile acts, and in some degree border upon treason. And farther, all these identical crimes, together with petit treason, and very many other acts of felony, are ousted of clergy by particular acts of parliament.

Upon the whole, we may observe the following rules. 1. That in all felonies, whether new created, or by common law, clergy is now allowable, unless taken away by act of parliament. 2. That where clergy is taken away from the principal, it is not of course taken away from the accessory, unless he be also particularly included in the words of the statute. 3. That when the benefit of clergy is taken away from the offence, (as in case of murder, huggery, robbery, rape, and burglary), a principal in the second degree, being present, aiding and abetting the crime, is as well excluded from his clergy as he that is a principal in the first degree: but, 4. That where it is only taken away from the person committing the offence (as in the case of stabbing, or committing larceny in a dwelling-house), his aiders and abettors are not excluded, through the tenderness of the law which hath determined that such statutes shall not be taken literally.

IV. Lastly, We are to inquire what the consequences are to the party, of allowing him this benefit of clergy. We speak not of the branding, imprisonment, or transportation; which are rather concomitant conditions, than consequences, of receiving this indulgence. The consequences are such as affect his present interest, and future credit and capacity: as having been once a felon, but now purged from that guilt

Clergy.

Clerk.

guilt by the privilege of clergy; which operates as a kind of statute pardon. And we may observe, 1. That, by his conviction, he forfeits all his goods to the king; which, being once vested in the crown, shall not afterwards be restored to the offender. 2. That, after conviction, and till he receives the judgment of the law by branding or the like, or else is pardoned by the king, he is, to all intents and purposes, a felon; and subject to all the disabilities and other incidents of a felon. 3. That, after burning or pardon, he is discharged for ever of that, and all other felonies before committed, within the benefit of clergy; but not of felonies from which such benefit is excluded: and this by statutes 8 Eliz. c. 4. and 18 Eliz. c. 7. 4. That, by the burning, or pardon of it, he is restored to all capacities and credits, and the possession of his lands, as if he had never been convicted. 5. That what is said with regard to the advantages of commoners and laymen, subsequent to the burning in the hand, is equally applicable to all peers and clergymen, although never branded at all. For they have the same privileges, without any burning, to which others are entitled after it.

CLERK (*clericus*), a word formerly used to signify a learned man, or man of letters. The word comes from the Greek *κληρικός*, used for *clergy*; but more properly signifying *lot* or *heritage*, in regard the lot and portion of clerks or ecclesiastics is to serve God. Accordingly, *clerus* was at first used to signify those who had a particular attachment to the service of God. The origin of the expression is derived from the Old Testament, where the tribe of Levi is called the *lot*, *heritage*, *κληρονομία*; and God is reciprocally called *their portion*; by reason that tribe was consecrated to the service of God, and lived on the offerings made to God, without any other settled provision as the rest had.

Thus, Pasquier observes, the officers of the counts (*comites*) were anciently created under the title of *clerks of accounts*; and secretaries of state were called, *clerks of the secret*. So, *clericus domini regis*, in the time of Edward I. was Englished, the *king's secretary*, or *clerk of his council*. The term was applied indifferently to all who made any profession of learning; or who knew how to manage the pen: though originally it was appropriated to ecclesiastics. As the nobility and gentry were usually brought up to the exercise of arms, there was none but the clergy left to cultivate the sciences: hence, as it was the clergy alone who made any profession of letters, a very learned man came to be called a *great clerk*; and a stupid ignorant man, a *bad clerk*.

CLERK is also applied to such as by their course of life exercise their pens in any court or office, of which there are various kinds: thus,

CLERK of the *Bails*, an officer in the court of king's bench, whose business is to file all bail-pieces taken in that court, where he always attends.

CLERK of the *Check*, an officer belonging the king's court, so called, because he has the check and controulment of the yeomen that belong to the king, queen, or prince. He likewise, by himself or deputy, sets the watch in the court. There is also an officer in the navy of the same name, belonging to the king's yards.

Clerk.

CLERK of the *Crown*, an officer in the king's bench, who frames, reads, and records all indictments against offenders, there arraigned or indicted of any public crime. He is likewise termed *clerk of the crown-office*, in which capacity he exhibits information by order of the court, for divers offences.

CLERK of the *Crown*, in chancery, an officer whose business it is constantly to attend the lord chancellor, in person or by deputy; to write and prepare for the great seal special matters of state by commission, both ordinary and extraordinary, viz. commissions of lieutenancy, of justices of assize,oyer and terminer, goal-delivery, and of the peace; all general pardons, granted either at the king's coronation, or in parliament: the writs of parliament, with the names of the knights, citizens, and burgesses, are also returned into his office. He also makes out special pardons and writs of execution on bonds of statute-staple forfeited.

CLERK of the *Deliveries*, an officer of the tower, whose function is to take indentures for all stores and ammunition issued from thence.

CLERK of the *Errors*, in the court of common pleas, an officer who transcribes and certifies into the king's bench, the tenor of the record of the action on which the writ of error, made out by the curfitor, is brought there to be determined. In the king's bench, the clerk of the errors transcribes and certifies the records of causes, by bill, in that court, into the exchequer. And the business of the clerk of the errors in the exchequer, is to transcribe the records certified thither out of the king's bench, and to prepare them for judgment in the exchequer-chamber.

CLERK of the *Essoins*, in the court of common pleas, keeps the essoin-roll, or enters essoins: he also provides parchment, cuts it into rolls, marks the number on them, delivers out all the rolls to every officer, and receives them again when written. See *Essoin*.

CLERK of the *Escheats*, an officer in the exchequer, who every term receives the escheats out of the lord-treasurer's remembrancer's office, and writes them out, to be levied for the crown.

CLERK of the *Green-cloth*. See *GREEN-CLOTH*.

CLERK of the *Hamper*, or *Hanaper*, an officer in chancery, whose business is to receive all money due to the king for the seals of charters, letters patent, commissions, and writs; also the fees due to the officers for enrolling and examining them.

CLERK-Comptroller of the *King's Household*, an officer of the king's court, authorised to allow or disallow the charges of pursuivants, messengers of the green-cloth, &c. to inspect and controul all defects of any of the inferior officers; and to fit in the counting-house with the lord-steward and other officers of the household, for regulating such matters.

CLERK of the *King's Silver*, an officer of the common pleas, to whom every fine is brought, after it has passed the office of the *enfos brevium*; and who enters the effect of writs of covenant, into a book kept for that purpose, according to which all the fines of that term are recorded in the rolls of the court.

CLERK of the *Market*, an officer of the king's house, to whom is given the charge of the king's measures and weights, the standards of those that ought to be used all over England.

CLERK

CLERK of the Nichils, or Nihilis, an officer of the exchequer, who makes a roll of all such sums as are nichilled by the sheriffs upon their estreats of green wax, and delivers them in to the remembrancer of the treasury, to have execution done upon them for the king. See **NIHIL**.

CLERK of the Outlawries, an officer of the common pleas, and deputy to the attorney-general, for making out all writs of *capias inlagatum*, after outlawry, to which there must be the king's attorney's name.

CLERK of the Paper-office, an officer belonging to the king's bench, whose business is to make up the paper-books of special pleadings in that court.

CLERK of the Peace, an officer belonging to the sessions of the peace, whose business is to read indictments, inrol the proceedings, and draw the process: he likewise certifies into the king's bench, transcripts of indictments, outlawries, attainders and convictions had before the justices of peace, within the time limited by statute, under a certain penalty. This office is in the gift of the *custos rotulorum*, and may be executed by deputy.

CLERK of the Pellis, an officer that belongs to the exchequer, whose business is to enter every teller's bill into a parchment-roll called *pellis receptorum*; and to make another roll of payments called *pellis exituum*.

CLERK of the petty Bag, an officer of the court of chancery, whereof there are three, the master of the rolls being the chief: their business is to record the return of all inquisitions out of every shire; to make out patents of customers, gaugers, comptrollers, &c. liberates upon extent of statutes-staple, *conge d'elires* for bishops, summons of the nobility, clergy, and burgesses to parliament; and commissions directed to knights and others of every shire, for assessing subsidies and taxes.

CLERK of the Pipe, an officer of the exchequer, who having the accounts of all debts due to the king, delivered out of the remembrancer's office, charges them in a great roll folded up like a pipe. He writes out warrants to sheriffs, to levy the said debts on the goods and chattels of the debtors: and if they have no goods, then he draws them down to the treasurer's remembrancer, to write estreats against their lands.

CLERK of the Pleas, an officer of the exchequer, in whose office all the officers of the court, having special privilege, ought to sue, or be sued, in any action. In this office also actions at law may be prosecuted by other persons, but the plaintiff ought to be tenant or debtor to the king, or some way accountable to him. The under clerks are attorneys in all suits.

CLERKS of the Privy-seal, four officers that attend the lord privy-seal, for writing and making out all things that are sent by warrant from the signet to the privy-seal, and to be passed the great-seal; and likewise to make out privy-seals, upon special occasions of his majesty's affairs, as for loan of money, or the like.

CLERK of the Rolls, an officer of the chancery, whose business is to make searches after, and copies of deeds, officers, &c.

CLERK of the Signet, an officer continually attending upon his majesty's principal secretary, who has the custody of the privy-signet, as well for sealing the king's private letters, as those grants which pass the

king's hand by bill signed. There are four of these officers who have their diet at the secretary's table.

CLERK, or WRITER, to the Signet, in Scots law. See **SCOTS LAW**, title 3.

SIX * CLERKS, officers in chancery, next in degree below the twelve masters, whose business is to inrol commissions, pardons, patents, warrants, &c. which pass the great-seal; they were anciently *clerici*, and forfeited their places if they married. There are also attorneys for parties in suits depending in the court of chancery.

CLERK of the Treasury, an officer belonging to the court of common pleas, who has the charge of keeping the records of the court, makes out all records of *nisi prius*, and likewise all exemplifications of records being in the treasury. He has the fees due for all searches; and has under him an under-keeper, who always keeps one key of the treasury-door.

CLERK of the Warrants, an officer of the common pleas, whose business is to enter all warrants of attorney for plaintiffs and defendants in suit; and to inrol deeds of bargain and sale, that are acknowledged in court, or before a judge. His office is likewise to estreat into the exchequer all issues, fines, estreats, and amercements, which grow due to the crown in that court.

CLERMONT, a considerable, rich, and populous town of France, in Auvergne, with a bishop's see. The cathedral, the public squares, and the walks, are very fine. Here is a bridge naturally formed, as they pretend, by the petrifying quality of a fountain. E. Long. 3. 18. N. Lat. 45. 47.

CLEROMANCY, a sort of divination performed by throwing lots, which were generally black and white beans, little clods of earth, or pebbles; also dice, or such like things, distinguished by certain characters. They cast the lots into a vessel, and having made supplication to the gods to direct them, drew them out, and, according to the characters, conjectured what should happen to them.

CLERVAL, a town of France, in the Franche comté, seated on the river Doux, belonging to the house of Wirtemberg, but depends on the crown of France. E. Long. 5. 57. N. Lat. 46. 35.

CLERVAUX, one of the most celebrated and finest abbeys of France, in Champagne, five miles from Bar-sur-Aube, and seated in a valley surrounded with woods and mountains. It is the chief of the Cistercian order. Here is the famous Ton of St Bernard, which will hold 800 tons of wine. Near this abbey is a small town.

CLETHRA, in botany, a genus of the monogynia order, belonging to the decandria class of plants. There is but one species, viz. the *Alnifolia*. This is a native of Virginia and Carolina, where it grows in moist places, and near the sides of rivulets, rising near eight or ten feet high. The leaves are shaped like those of the alder-tree, but longer: these are placed alternately upon the branches: the flowers are produced in close spikes at the extremities of the branches: they are white, composed of five petals, and have ten stamina in each, nearly of the same length with the petals. This is hardly enough to bear the open air in Britain, and is one of the most beautiful flowering shrubs.

Cleveland
Cliffortia.

shrubs. Its season is commonly about the beginning of July; and, if the season is not very hot, there will be part of the spikes in beauty till the middle of September. This shrub will thrive best in moist land, and requires a sheltered situation, where it may be defended from strong winds, which frequently break off the branches where they are too much exposed to their violence. It is propagated by layers, but they are generally two years before they take root. It may also be propagated by suckers, which are sent out from the roots: if these are carefully taken off with fibres in the autumn, and planted in a nursery-bed, they will be strong enough in two years to transplant where they are to remain.

CLEVELAND, a district in the north riding of Yorkshire in England, from whence the noble family of Fitzroy takes the title of Duke.

CLEVELAND (John), an English poet of some eminence in his time, who during the civil war under Charles I. engaged as a literary champion in the royal cause against the parliamentarians. He died in 1658, and was much extolled by his party. His works, which consist of poems, characters, orations, epistles, &c. were printed in octavo in 1677.

CLEVES, the duchy of, a province of the circle of Westphalia, in Germany. It is divided into two parts by the Rhine, and is about 40 miles in length from east to west, and 20 in breadth from north to south. It is a fine agreeable country, and pretty populous. The towns are, Cleves the capital, Calcar, Gennep, Sauten, Orfey, Bureck, and Greit. These lie on the left side the river. On the right, Duysburg, Welfe, Rees, and Emmerick. There have been great contests about this duchy, but it now belongs to the king of Prussia.

CLEVES, a city of Germany, in the duchy of Cleves, of which it is the capital. It stands upon a pleasant hill, about three miles from the Rhine, with which it communicates, by means of a canal which is large enough for great barges. The castle stands upon a mountain, and, though old, is very agreeable. Calvinists, Lutherans, and Roman Catholics, are all tolerated in this city. E. Long. 5. 36. N. Lat. 51. 40.

CLIENT, among the Romans, a citizen who put himself under the protection of some great man, and, in respect of that relation, was called *patron*.

This patron assisted his client with his protection, interest, and goods; and the client gave his vote for his patron, when he fought any office for himself or his friends. Clients owed respect to their patrons, as these owed them their protection.

The right of patronage was appointed by Romulus, to unite the rich and poor together, in such a manner as that one might live without contempt, and the other without envy; but the condition of a client, in course of time, became little else but a moderate slavery.

CLIENT is now used for a party in a law-suit, who has turned over his cause into the hands of a counsel-lor or solicitor.

CLIFFORTIA, in botany; a genus of the polyandria order, belonging to the diœcia class of plants. There are three species, all of them natives of Africa; so require to be kept in a green-house when cultivated

in this country. Their flowers make no great appearance; but the plants themselves are very ornamental evergreens. They grow to the height of four or five feet; and are propagated by cuttings, which must be young shoots of five or six inches length. If these are planted in pots in spring or summer, and plunged in a hot-bed, they will readily take root. They must be watered plentifully in summer, but very sparingly in winter.

CLIMACTERIC, among physicians, (from *climacter*, a ladder,) a critical year in a person's life.

According to some, this is every seventh year; but others allow only those years produced by multiplying 7 by the odd number 3, 5, 7, and 9, to be climacterical. These years, they say, bring with them some remarkable change with respect to health, life, or fortune: the grand climacteric is the 63^d year; but some, making two, add to this the 81st: the other remarkable climacterics are the 7th, 21st, 35th, 49th, and 56th.

CLIMATE, CLIMA, or CLIME, in geography, a part of the surface of the earth, bounded by two circles parallel to the equator; and of such a breadth, as that the longest day in the parallel nearer the pole, exceeds the longest day in that next the equator by some certain spaces; viz. half an hour. The word comes from the Greek *κλίμα*, *inclinationum*, an inclination.

The Beginning of the CLIMATE, is a parallel circle wherein the day is the shortest. The End of the CLIMATE, is that wherein the day is the longest. The climates therefore are reckoned from the equator to the pole; and are so many bands, or zones, terminated by lines parallel to the equator: though, in strictness, there are several climates in the breadth of one zone. Each climate only differs from its contiguous ones, in that the longest day in summer is longer or shorter by half an hour in the one place than in the other. As the climates commence from the equator, the first climate at its beginning has its longest day precisely 12 hours long; at its end, 12 hours and an half: the second, which begins where the first ends, viz. at 12 hours and an half, ends at 13 hours; and so of the rest, as far as the polar circles, where, what the geographers call *hour-climates* terminate, and *month-climates* commence. As an hour-climate is a space comprised between two parallels of the equator, in the first of which the longest day exceeds that in the latter by half an hour; so the month-climate is a space terminated between two circles parallel to the polar circles, whose longest day is longer or shorter than that of its contiguous one by a month or 30 days.

The ancients, who confined the climates to what they imagined the habitable parts of the earth, only allowed of seven. The first they made to pass through Mevoe, the second through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the sixth through Pontus, and the seventh through the mouth of the Borythenes. The moderns, who have failed further toward the poles, make 30 climates on each side; and, in regard the obliquity of the sphere makes a little difference in the length of the longest day, instead of half an hour, some of them only make the difference of climates a quarter.

Climate.
Climate.

Vulgarly the term *climate* is bestowed on any country or region differing from another either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants; without any regard to the length of the longest day. Abulfeda, an Arabic author, distinguishes the first kind of climates by

the term *real climates*, and the latter by that of *apparent climates*. Varenus gives us a table of 30 climates; but without any regard to the refraction. Ricciolus furnishes a more accurate one, wherein the refractions are allowed for; an abstract of which follows:

Middle of Clim.	Longest Day.	Latit.	Middle of Clim.	Longest Day.	Latit.	Middle of Clim.	Latit.	Cont. Light.	North Night.	Cont. Light.	South Night.
I	12 ^h 30	7° 18	VIII	16 ^h 04 ⁸ 15		XV	66° 53	31 ^d	27 ^d	30 ^d	28 ^d
II	13 0 15	36	IX	17 0 53 46		XVI	69 30	62	58	60	59
III	13 30 23	8	X	18 0 57 44		XVII	73 0	93	87	89	88

VII	15 30 44	42	XIV	24 0 65 54							

CLIMAX, or GRADATION, in rhetoric, a figure wherein the word or expression which ends the first member of a period begins the second, and so on; so that every member will make a distinct sentence, taking its rise from the next foregoing, till the argument and period be beautifully finished; as in the following gradation of Dr Tillotson: "After we have practised good actions a while, they become easy; and when they are easy, we begin to take pleasure in them; and when they please us, we do them frequently; and by frequency of acts, a thing grows into a habit; and confirmed habit is a kind of second nature; and so far as any thing is natural, so far it is necessary; and we can hardly do otherwise; nay, we do it many times when we do not think of it."

CLINCH, in the sea-language, that part of a cable which is bended about the ring of the anchor, and then seized or made fast.

CLINCHING, in the sea-language, a kind of slight caulking used at sea, in a prospect of foul weather, about the posts: it consists in driving a little oakum into their seams, to prevent the water coming in at them.

CLINIC, a term applied by the ancient church-historians to those who received baptism on their death-bed. See BAPTISM.

CLINIC *Medicine*, was particularly used for the method of visiting and treating sick persons in bed, for the more exact discovery of all the symptoms of their disease.

CLINIAS, a Pythagorean philosopher, and musician, in the 65th Olympiad. He was wont to assuage his passion, being very choleric, by his lyre.

CLINOPODIUM, FIELD-BASIL, a genus of the gymnospermia order, belonging to the didymiaia class of plants. There are six species, all of them herbaceous plants, growing from one to two feet high. They are remarkable only for their strong odour, being somewhat between marjoram and basil.

CLIO, in pagan mythology, the daughter of Jupiter and Mnemosyne, was the muse who presided over history. She is generally represented under the form of a young woman crowned with laurel, holding in her right hand a trumpet, and in her left a book.

CLIO, in zoology, a genus of insects belonging to the order of vermes mollusca. The body is oblong and fitted for swimming; and it has two membranaceous

wings placed opposite to each other. The species are three, principally distinguished by the shape of their vagina, and all natives of the ocean.

CLIPSEUS, in natural history, a name given to the flat depressed centronia, from their resembling a shield. See CENTRONIA.

CLISTHENES, a famous Athenian magistrate, the author of the mode of banishing ambitious citizens by ostracism, or writing their names upon a shell: the intention was patriotic, but it was abused like all other human institutions; some of the worthiest citizens of Athens being thus exiled. See ATTICA, n° 79; and OSTRACISM. He died 510 years before Christ.

CLITOMACHUS the philosopher, flourished about 140 years before Christ. He was born at Carthage; quitted his country at 40 years of age; and went to Athens, where he became the disciple and successor of Carneades. He composed many books, but they are all lost.

CLITORIA, in botany; a genus of the decandria order, belonging to the diadelphia class of plants. There are four species, all of them herbaceous perennials, or annuals, of the kidney-bean kind, growing naturally in both the Indies. The stalk is climbing, slender, and of the height of a man. The leaves are winged, placed alternately, and consist of two, three, or five pair of lobes, terminated by an odd one. The flowers, which are elegant, stand singly, each on its proper foot-stalk. They are very large, and generally of a deep blue, but sometimes of a white colour. From the fruit of this plant is distilled an eye-water. The beans reduced to powder, and taken in broth, to the quantity of two drachms, prove a gentle purge; and Grimmer remarks, in his *Labor Ceyl.* that the powder of the dried beans, being mixed with the milk of the cocoa nut, or with broth, and administered in quantity from one to three drachms, not only mitigates colic pains, but is very useful, and much used in Ceylon, in all disorders of the stomach and bowels. These plants are propagated by seeds; and, in this country, must be kept continually in a stove.

CLITORIS, in anatomy, is a part of the external pudenda, situated at the angle which the nymphæ form with each other*. Like the penis it has an erection, * See *Ana-* and it is thought to be the principal seat of venereal *tomy*, pleasure. The clitoris is of different sizes in different n° 372. & women; but in general it is small, and covered with

Clitus
||
Clive.

the labia. The preter-naturally enlarged clitoris is what constitutes an hermaphrodite. When the clitoris is too large, it may be so extirpated as to remove the unnecessary part; but this requires much care, for a farther extirpation subjects the patient to an involuntary discharge of urine.

CLITUS, brother to Alexander the Great's nurse, followed that prince in his conquests, and saved his life by cutting off the hand of Roxaces, which held an ax lifted up to kill him at the passage of the Granicus. Alexander, who had a great regard for him, some time after invited him to supper; when Clitus, at the end of the repast, being heated with wine, diminished the exploits of that prince, in order to magnify those of Philip his father. This so enraged Alexander, that he killed him with his own hand; but he was afterwards so afflicted at it, that he attempted his own life.

CLIVE (Robert) lord, son of Richard Clive Esq; of Styche near Drayton in Salop, was born in 1725. Toward the close of the war in 1741, he was sent as a writer in the East India service, to Madras; but being fonder of the camp than the counting-house, he soon availed himself of an opportunity to exchange his pen for a pair of colours. He first distinguished himself at the siege of Pondicherry in 1748; acted under major Laurence at the taking of Devi Cotta in Tanjore, who wrote of his military talents in high terms; commanded a small party for the taking of Arcot, and afterward defended that place against the French; and performed many other exploits, which, considering the remoteness of the scene of action, would require a long detail to render sufficiently intelligible. He was however, in brief, looked upon and acknowledged as the man who first roused his countrymen to spirited action, and raised their reputation in the East: so that when he came over to England in 1753, he was presented, by the court of directors, with a rich sword set with diamonds, as an acknowledgment of past, and an incitement to future, services. Captain Clive returned to India in 1755, as governor of fort St David, with the rank of lieutenant-colonel in the king's troops; when as commander of the company's troops, he, in conjunction with admiral Watson, reduced Angria the pirate, and became master of Geria his capital, with all his accumulated treasure. On the loss of Calcutta and the well known barbarity of the soubah Surajah Dowla, they failed to Bengal; where they took fort William, in January 1757, and colonel Clive defeating the soubah's army soon after, accelerated a peace. Surajah Dowla's perfidy, however, soon produced fresh hostilities, which ended in his ruin; he being totally defeated by colonel Clive at the famous battle of Plassey. The next day the conqueror entered Muxadabad in triumph; and placed Jaffer Ally Cawn, one of the principal generals on the throne: the deposed soubah was soon after taken, and privately put to death by Jaffer's son. Admiral Watson died at Calcutta; but colonel Clive commanded in Bengal the two succeeding years: he was honoured by the Mogul with the dignity of an Omrah of the empire; and was rewarded by the new soubah with a grant of lands, or a jaghire, producing 27,000l. a-year. In 1760, he returned to England,

where he received the unanimous thanks of the company, was elected member of parliament for Shrewsbury, and was raised to an Irish peerage by the title of Lord Clive Baron of Plassey. In 1764, fresh disturbances taking place in Bengal, lord Clive was esteemed the only man qualified to settle them, and was accordingly again appointed to that presidency; after being honoured with the order of the Bath, and with the rank of major-general. When he arrived in India, he exceeded the most sanguine expectation, in restoring tranquility to the province without striking a blow; and fixed the highest ideas of the British power in the minds of the natives. He returned home in 1767; and, in 1772, when a parliamentary inquiry into the conduct of the East India company was agitated, he entered into an able justification of himself in a masterly speech in the house of commons. He died suddenly towards the close of the year 1774.

CLOACÆ, in antiquity, the common sewers of Rome, to carry off the dirt and soil of the city into the Tiber; justly reckoned among the grand works of the Romans. The first common sewer, called *Cloaca Maxima*, was built by Tarquinius, some say Priscus, others Superbus, of huge blocks of stone joined together without any cement, in the manner of the edifices of those early times; consisting of three rows of arches one above another, which at length conjoin and unite together; measuring in the clear 18 palms in height, and as many in width. Under these arches they rowed in boats; which made Pliny say that the city was suspended in air, and that they sailed beneath the houses. Under these arches also were ways through which carts loaded with hay could pass with ease. It began in the Forum Romanum; measured 300 paces in length; and emptied itself between the temple of Vesta and the Pons Senatorius. There were as many principal sewers as there were hills. Pliny concludes their firmness and strength from their standing for so many ages the shocks of earthquakes, the fall of houses, and the vast loads and weights moved over them.

CLOACINA, the goddess of jokes and common sewers, among the ancient Romans.

CLOCK, a machine constructed in such a manner, and regulated by such uniform movements, as to measure time, and all its subdivisions, with great exactness.

The invention of clocks with wheels is referred to Pacificus, archdeacon of Verona, who lived in the time of Lotharius son of Louis the Debonnaire, on the credit of an epitaph quoted by Ughelli, and borrowed by him from Panvinus. They were at first called nocturnal dials, to distinguish them from sun-dials, which shewed the hour by the sun's shadow. Others ascribe the invention to Boethius, about the year 510. Mr Derham makes clock-work of a much older standing; and ranks Archimedes's sphere mentioned by Claudian, and that of Ptolemy mentioned by Cicero, among the machines of this kind: not that either their form or use were the same with those of ours, but that they had their motion from some hidden weights or springs, with wheels, or pulleys, or some such clock-work principle. But be this as it will, it is certain the art of making clocks, such as are now in use, was either first invented, or at least retrieved, in Germany, about

Clock
||
Clock.

about 200 years ago. The water-clocks, or clepsydræ, and sun-dials, have both a much better claim to antiquity. The French annals mention one of the former kind sent by Aaron, king of Persia, to Charlemagne, about the year 807, which seemed to bear some resemblance to the modern clocks: it was of brass, and shewed the hours by twelve little balls of the same metal, which fell at the end of each hour, and in falling struck a bell and made it sound. There were also figures of 12 cavaliers, which at the end of each hour came forth at certain apertures or windows in the side of the clock, and shut them again, &c.

The invention of pendulum-clocks is owing to the happy industry of the last age: the honour of it is disputed by Huygens and Galileo. The former, who has written a volume on the subject, declares it was first put in practice in the year 1657, and the description thereof printed in 1658. Becher, *de Nova Temporis Dimensiendi Theoria*, anno 1680, sticksles for Galileo; and relates, though at second-hand, the whole history of the invention; adding, that one Treller, clock-maker to the then father of the grand-duke of Tuscany, made the first pendulum-clock at Florence, by direction of Galileo Galilei; a pattern of which was brought into Holland. The academy de'l Cimento say expressly, that the application of the pendulum to the movement of a clock was first proposed by Galileo, and first put in practice by his son Vincenzo Galilei, in 1649. Be the inventor who he will, it is certain the invention never flourished till it came into Huygens's hands, who insists on it, that if ever Galileo thought of such a thing, he never brought it to any degree of perfection. The first pendulum-clock made in England, was in the year 1622, by Mr Fromant, a Dutchman.

Amongst the modern clocks, those of Strasburg and Lyons are very eminent for the richness of their furniture, and the variety of their motions and figures. In the first, a cock claps his wings, and proclaims the hour; the angel opens a door, and salutes the virgin; and the holy Spirit defends on her, &c. In the second, two horsemen encounter, and beat the hour on each other: a door opens, and there appears on the theatre the virgin, with Jesus Christ in her arms; the magi, with their retinue, marching in order, and presenting their gifts; two trumpeters, founding all the while to proclaim the procession. These, however, are excelled by two lately made by English artists, and intended as a present from the East India company to the emperor of China. The clocks we speak of are in the form of chariots, in which are placed, in a fine attitude, a lady, leaning her right hand upon a part of the chariot, under which is a clock of curious workmanship, little larger than a shilling, that strikes and repeats, and goes eight days. Upon her finger sits a bird finely modelled, and set with diamonds and rubies, with its wings expanded in a flying posture, and actually flutters for a considerable time on touching a diamond button below it; the body of the bird (which contains part of the wheels that in a manner give life to it) is not the bigness of the 16th part of an inch. The lady holds in her left hand a gold tube not much thicker than a large pin, on the top of which is a small round box, to which a circular ornament set with

diamonds not larger than a fixpence is fixed, which goes round near three hours in a constant regular motion. Over the lady's head, supported by a small fluted pillar no bigger than a quill, is a double umbrella, under the largelt of which a bell is fixed at a considerable distance from the clock, and seems to have no connection with it; but from which a communication is secretly conveyed to a hammer, that regularly strikes the hour, and repeats the same at pleasure, by touching a diamond button fixed to the clock below. At the feet of the lady is a gold dog; before which from the point of the chariot are two birds fixed on spiral springs; the wings and feathers of which are set with stones of various colours, and appear as if flying away with the chariot, which, from another secret motion, is contrived to run in a straight, circular, or any other direction; a boy that lays hold of the chariot behind, seems also to push it forward. Above the umbrella are flowers, and ornaments of pearls, rubies, and other precious stones; and it terminates with a flying dragon set in the same manner. The whole is of gold, most curiously executed, and embellished with gold, rubies, and pearls.

Of the Mechanism of Clocks, and how they measure Time. The first figure of Plate LXXX is a profile of a clock: P is a weight that is suspended by a rope that winds about the cylinder or barrel C, which is fixed upon the axis *a a*; the pivots *b b* go into holes made in the plates TS, TS, in which they turn freely. These plates are made of brass or iron, and are connected by means of four pillars ZZ; and the whole together is called the frame.

The weight P, if not restrained, would necessarily turn the barrel C with an uniform accelerated motion, in the same manner as if the weight was falling freely from a height. But the barrel is furnished with a ratchet wheel K K, the right side of whose teeth strikes against the click, which is fixed with a screw to the wheel D D, as represented in fig. 2. so that the action of the weight is communicated to the wheel D D, the teeth of which act upon the teeth of the small wheel *d* which turns upon the pivots *c c*. This communication of the teeth of one wheel with another, is called *engrenage* or *pitching*; and a small wheel, like *d*, is called a *pinion*.

The wheel E E is fixed upon the axis of the pinion *d*; and the motion communicated to the wheel D D by the weight is transmitted to the pinion *d*, consequently to the wheel E E, as likewise to the pinion *e*, and wheel F F, which moves the pinion *f*, upon the axis of which the crown or balance wheel G H is fixed. The pivots of the pinion *f* play in holes of the plates L M which are fixed horizontally to the plates T S. In a word, the motion begun by the weight is transmitted from the wheel G H to the palettes I K, which communicates its motion, by means of the fork U X riveted on the palettes, to the pendulum A B, which is suspended upon the hook A. The pendulum A B describes, round the point A, an arc of a circle alternately going and returning. If then the pendulum be once put in motion by a push of the hand, the weight of the pendulum at B will make it return upon itself, and it will continue to go alternately backward and forward till the resistance of the air upon the pen-

dulum, and the friction at the point of suspension at A, destroys the original impressed force. But as, at every vibration of the pendulum, the teeth of the balance-wheel G H act so upon the palettes I K, (the pivots upon the axis of these palettes play in two holes of the potence s t ;) that after one tooth H has communicated motion to the palette K, that tooth escapes; and then the opposite tooth G acts upon the palette I, and escapes in the same manner; and thus each tooth of the wheel escapes the palettes I, K, after having communicated their motion to the palettes in such a manner that the pendulum, instead of being stop'd, continues to move.

The wheel E E revolves in an hour; the pivot e of this wheel passes through the plate, and is continued to r ; upon the pivot is a wheel N N with a long socket fastened in the centre; upon the extremity of this socket r the minute-hand is fixed. The wheel N N acts upon the wheel O; the pinion of which, p , acts upon the wheel $g g$, fixed upon a socket which turns along with the wheel N. This wheel $g g$ makes its revolution in 12 hours, upon the barrel of which the hour-hand is fixed.

From the above description it is easy to see, 1. That the weight p turns all the wheels, and at the same time continues the motion of the pendulum. 2. That the quickness of the motion of the wheels is determined by that of the pendulum. 3. That the wheels point out the parts of time divided by the uniform motion of the pendulum.

When the cord upon which the weight is suspended is entirely run down from off the barrel, it is wound up again by means of a key, which goes on the square end of the arbor at Q, by turning it in a contrary direction from that in which the weight descends. For this purpose, the inclined side of the teeth of the wheel R (fig. 2.) removes the click C, so that the ratchet-wheel R turns while the wheel D is at rest: but as soon as the cord it wound up, the click falls in between the teeth of the wheel D, and the right side of the teeth again act upon the end of the click, which obliges the wheel D to turn along with the barrel; and the spring A keeps the crank between the teeth of the ratchet-wheel R.

We shall now explain how time is measured by the motion of the pendulum; and how the wheel E, upon the axis of which the minute-hand is fixed, makes but one precise revolution in an hour. The vibrations of a pendulum are performed in a shorter or longer time in proportion to the length of the pendulum itself. A pendulum of 3 feet 8½ French lines in length, makes 3600 vibrations in an hour: i. e. each vibration is performed in a second of time, and for that reason it is called a *second pendulum*. But a pendulum of 9 inches 2½ French lines makes 7200 vibrations in an hour, or two vibrations in a second of time, and is called a *half-second pendulum*. Hence, in constructing a wheel whose revolution must be performed in a given time, the time of the vibrations of the pendulum which regulates its motion must be considered. Supposing, then, that the pendulum AB makes 7200 vibrations in an hour, let us consider how the wheel E shall take up an hour in making one revolution. This entirely depends on the number of teeth in the wheels and

pinions. If the balance-wheel consists of 30 teeth, it will turn once in the time that the pendulum makes 60 vibrations: for at every turn of the wheel, the same tooth acts once on the palette I, and once on the palette K, which occasions two separate vibrations in the pendulum; and the wheel having 30 teeth, it occasions twice 30, or 60 vibrations. Consequently, this wheel must perform 120 revolutions in an hour; because 60 vibrations, which it occasions at every revolution, are contained 120 times in 7200, the number of vibrations performed by the pendulum in an hour. Now, in order to determine the number of teeth for the wheels E F, and their pinions $e f$, it must be remarked, that one revolution of the wheel E must turn the pinion e as many times as the number of teeth in the pinion is contained in the number of teeth in the wheel. Thus, if the wheel E contains 72 teeth, and the pinion e 6, the pinion will make 12 revolutions in the time that the wheel makes 1; for each tooth of the wheel drives forward a tooth of the pinion, and when the 6 teeth of the pinion are moved, a complete revolution is performed; but the wheel E has by that time only advanced 6 teeth, and has still 66 to advance before its revolution be completed, which will occasion 11 more revolutions of the pinion. For the same reason, the wheel F having 60 teeth, and the pinion f 6, the pinion will make 10 revolutions while the wheel performs one. Now, the wheel F being turned by the pinion e , makes 12 revolutions for one of the wheel E; and the pinion f makes 10 revolutions for one of the wheel F; consequently, the pinion f performs 10 times 12 or 120 revolutions in the time the wheel E performs one. But the wheel G, which is turned by the pinion f , occasions 60 vibrations in the pendulum each time it turns round; consequently the wheel G occasions 60 times 120 or 7200 vibrations of the pendulum while the wheel E performs one revolution; but 7200 is the number of vibrations made by the pendulum in an hour, and consequently the wheel E performs but one revolution in an hour; and so of the rest.

From this reasoning, it is easy to discover how a clock may be made to go for any length of time without being wound up: 1. By increasing the number of teeth in the wheels. 2. By diminishing the number of teeth in the pinions. 3. By increasing the length of the cord that suspends the weight: and lastly, by adding to the number of wheels and pinions. But, in proportion as the time is augmented, if the weight continues the same, the force which it communicates to the last wheel G H will be diminished.

It only remains to take notice of the number of teeth in the wheels which turn the hour and minute hands.

The wheel E performs one revolution in an hour; the wheel N N, which is turned by the axis of the wheel E, must likewise make only one revolution in the same time; and the minute-hand is fixed to the barrel of this wheel. The wheel N has 30 teeth, and acts upon the wheel O, which has likewise 30 teeth, and the same diameter; consequently the wheel O takes one hour to a revolution: now the wheel O carries the pinion p , which has 6 teeth, and which acts upon the wheel $g g$ of 72 teeth; consequently the pin-

nion *p* makes 12 revolutions while the wheel *qg* makes one, and of courfe the wheel *qg* takes 12 hours to one revolution; and upon the barrel of this wheel the hour-hand is fixed. We fhall conclude with remarking, that all that has been faid here concerning the revolutions of the wheels, &c. is equally applicable to watches as to clocks. See the article *WATCH*, to which the other figures on the plate relate.

CLODIUS (Publius), the Roman fenator; a factitious citizen, whole party became very powerful in Rome, and procured the banifhment of Cicero*. He was killed on the Appian way by one of Milo's fervants, 53 years before Chrift.

CLOGHER, an epifcopal town of Ireland, in the county of Tyrone, and province of Ulfter. It fends two members to parliament. W. Long. 7. 30. N. Lat. 54. 16.

CLOISTER, (Clausfrum,) a habitation furrounded with walls, and inhabited by canons or religious, &c. In a more general fenfe, cloifter is ufed for a monaftery of religious of either fex. In a more reftained fenfe, cloifter is ufed for the principal part of a regular monaftery, confifting of a fquare built around; ordinarily between the church, the chapter-houle, and the refectory; and over which is the dormitory. The cloifters ferved for feveral purpofes in the ancient monafteries. Petrus Blefenfis obferves, that it was here the monks held their lectures: the lecture of morality at the north-fide, next the church; the fchool on the weft, and the chapter on the eaft; fpiritual meditation, &c. being referved for the church. Lanfranc obferves, that the proper ufe of the cloifter was for the monks to meet in, and converse together, at certain hours of the day.

The form of the cloifter was fquare; and it had its name *clausfrum*, from *claudo*, "I fhut or clofe;" as being inclofed on its four fides with buildings. Hence, in architecture, a building is ftill faid to be in form of a cloifter, when there are buildings on each of the four fides of the court.

CLOSE, in heraldry. When any bird is drawn in a coat of arms with its wings clofe down about it, (*i. e.* not difplayed), and in a ftanding pofture; they blazon it by this word *clofe*; but if it be flying, they call it *volant*. See *VOLANT*.

CLOSE, in mufic. See *CADENCE*.

CLOSE-HAULED, in navigation, the general arrangement or trim of a fhip's fails when the endeavours to make a progrefs in the neareft direction poffible towards that point of the compafs from which the wind blows. In this manner of failing, the keel commonly makes an angle of fix points with the line of the wind; but floops and fome other fmall veffels are faid to fail almoft a point nearer. All veffels, however, are fupposed to make nearly a point of lee-way when clofe-hauled, even when they have the advantage of a good failing breeze and fmooth water. The angle of lee-way, however, increafes in proportion to the increafe of the wind and fea. In this difpofition of the fails, they are all extended fide ways on the fhip, fo that the wind, as it croffes the fhip obliquely toward the ftern from forwards, may fill their cavities. But as the current of winds alfo enters the fails in an oblique direction, the effort of it to make the fhip advance

is confiderably diminished: fhe will therefore make the leaft progrefs when failing in this manner. The fhip is faid to be clofe-hauled, becaufe at this time her *tacks*, or lower corners of the principal fails, are drawn clofe down to her fide to windward, the fheets hauled clofe-aft, and all the bow-lines drawn to their greateft extension to keep the fails fteady.

CLOSE-Quarters, certain ftrong barriers of wood, ftretching acrofs a merchant-fhip in feveral places. They are ufed as places of retreat when a fhip is boarded by her adverfary, and are therefore fitted with feveral fmall loop-holes through which to fire the fmall arms, and thereby annoy the enemy and defend themfelves. They are likewife furnifhed with feveral caifons called *powder-cheffts*, which are fixed upon the deck, and filled with powder, old-nails, &c. and may be fired at any time from the clofe-quarters upon the boarders.

We have known an Englifh merchant-fhip of 16 guns, and properly fitted with clofe-quarters, defeat the united efforts of three French privateers who boarded her in the laft war, after having engaged at fome diftance nearly a day and a half, with very few intervals of reft. Two of the cruifers were equipped with twelve guns each, and the other with eight. The French failors were, after boarding, fo much expofed to continued fire of mulquetry and coehorns charged with grenades, that a dreadful fcene of carnage enfued, in which the decks were foon covered with the dead bodies of the enemy, feveral of the boarders, in their hurry to efcape, had left behind.

CLOT-HERRD; a fpecies of *FRINGILLA*.

CLOTH, in commerce, a manufacture made of wool, wove in the loom.

Cloths are of divers qualities, fine or courfe. The goodnefs of cloth, according to fome, confifts in the following particulars. 1. That the wool be of a good quality, and well drefsed. 2. It muft be equally fpun, carefully obferving that the thread of the warp be finer and better twifted than that of the woof. 3. The cloth muft be well wrought, and beaten on the loom, fo as to be every where equally compaét. 4. The wool muft not be finer at one end of the piece than in the reft. 5. The lifts muft be fufficiently ftrong, of the fame length with the ftuff, and muft confift of good wool, hair, or oftich-feathers; or, what is ftill better, of Daniſh dog's hair. 6. The cloth muft be free from knots, and other imperfections. 7. It muft be well fcoured with fuller's earth, well filled with the beft white foap, and afterwards wafhed in clear water. 8. The hair or nap muft be well drawn out with the teazel, without being too much opened. 9. It muft be fhorn clofe without making it thread-bare. 10. It muft be well dried. 11. It muft not be tender-ftretched, to force it to its juft dimenfions. 12. It muft be preffed cold, not hot preffed, the latter being very injurious to woolen cloth.

Manufacturing of white Cloths which are intended for dyeing. The beft wool for the manufacturing of cloths are thofe of England and Spain, efpecially thofe of Lincolnfhire and Segovia. To ufe thofe wools to the beft advantage, they muft be fcoured, by putting them into a liquor fomewhat more than lukewarm,

Clofe
Cloth.

Falconer's
Dict. of the
Marine.

Cloth. composed of three parts fair water, and one of urine. After the wool has continued long enough in the liquor to soak, and dissolve the grease, it is drained and well washed in running water. When it feels dry, and has no smell but the natural one of the sheep, it is said to be duly scoured.

After this, it is hung to dry in the shade; the heat of the sun making it harsh and inflexible: when dry, it is beat with rods upon hurdles of wood, or on cords, to cleanse it from dust and the grosser filth; the more it is thus beat and cleaned, the softer it becomes, and the better for spinning. After beating, it must be well picked, to free it from the rest of the filth that had escaped the rods.

It is now in a proper condition to be oiled, and carded on large iron cards placed slopewise. Olive oil is esteemed the best for this purpose: one fifth of which should be used for the wool intended for the woof, and a ninth for that designed for the warp. After the wool has been well oiled, it is given to the spinners, who first card it on the knee with small fine cards, and then spin it on the wheel, observing to make the thread of the warp smaller by one third than that of the woof, and much compacter twisted.

The thread thus spun, is reeled, and made into skeins. That designed for the woof is wound on little tubes, pieces of paper, or rushes, so disposed as that they may be easily put in the eye of the shuttle. That for the warp is wound on a kind of large wooden bobbins, to dispose it for warping. When warped, it is stiffened with size; the best of which is that made of shreds of parchment; and when dry, is given to the weavers, who mount it on the loom.

The warp thus mounted, the weavers, who are two to each loom, one on each side, tread alternately on the treadle, first on the right step, and then on the left, which raises and lowers the threads of the warp equally; between which they throw transversely the shuttle from the one to the other: and every time that the shuttle is thus thrown, and a thread of the woof inserted within the warp, they strike it conjointly with the same frame, wherein is fastened the comb or reed, between whose teeth the threads of the warp are passed, repeating the stroke as often as is necessary.

The weavers having continued their work till the whole warp is filled with the woof, the cloth is finished; it is then taken off the loom by unrolling it from the beam whereon it had been rolled in proportion as it was wove; and now given to be cleaned of the knots, ends of threads, straws, and other filth, which is done with iron nippers.

In this condition it is carried to the fullery, to be scoured with urine, or a kind of potter's clay, well steeped in water, put along with the cloth in the trough wherein it is filled. The cloth being again cleared from the earth or urine, is returned to the former hands to have the lesser filth, small straws, &c. taken off as before: then it is returned to the fuller to be beat and filled with hot water, wherein a suitable quantity of soap has been dissolved; after fulling, it is taken out to be smoothed, or pulled by the lifts lengthwise, to take out the wrinkles, crevices, &c.

The smoothing is repeated every two hours, till

the fulling be finished, and the cloth brought to its proper breadth: after which it is washed in clear water, to purge it of the soap, and given wet to the carders to raise the hair or nap on the right side with the thistle or weed. After this preparation the cloth-worker takes the cloth, and gives it its first cut or shearing; then the carders return it, and after wetting, give it as many more courses with the teazle, as the quality of the stuff requires, always observing to begin against the grain of the hair, and to end with it; as also to begin with a smoother thistle, proceeding still with one sharper and sharper, as far as the sixth degree.

After these operations, the cloth being dried, is returned to the cloth-worker, who sheers it a second time, and returns it to the carders, who repeat their operation as before, till the nap be well ranged on the surface of the cloth, from one end of the piece to the other.

The cloth thus wove, scoured, napped, and shorn, is sent to the dyer; when dyed, it is washed in fair water, and the worker takes it again wet as it is, lays the nap with a brush on the table, and hangs it on the tenters, where it is stretched both in length and breadth sufficiently to smooth it, set it square, and bring it to its proper dimensions, without straining it too much; observing to brush it across, the way of the nap, while a little moist, on the tenters.

When quite dry, the cloth is taken off the tenters, and brushed again on the table, to finish the laying of the nap; after which it is folded, and laid cold under a press, to make it perfectly smooth and even, and give it a gloss.

Lastly, the cloth being taking out of the press, and the papers, &c. for glossing it removed, it is in a condition for sale or use. With regard to the manufacture of mixt cloths, or those wherein the wools are first dyed, and then mixt, spun and wove of the colours intended, the process, except what relates to the colour, is mostly the same with that just represented.

Cloth made from Vegetable Filaments. See BARK and FILAMENTS.

Incombustible CLOTH. See ASBESTOS.

CLOUD, a collection of vapours suspended in the atmosphere.

That the clouds are formed from the aqueous vapours which before were so closely united with the atmosphere as to be invisible, is universally allowed: but it is no easy matter to account for the long continuance of some very opaque clouds without dissolving; or to give a reason why the vapours, when they have once begun to condense, do not continue to do so till they at last fall to the ground in the form of rain or snow, &c. Under the article **BAROMETER**, n° 23. we have hinted at the general cause of the formation of clouds, namely, a separation of the latent heat from the water whereof the vapour is composed. The consequence of this separation, as is undeniably proved by Dr Black, must be the condensation of that vapour, in some degree at least: in such case, it will first appear as a smoke, mist, or fog; which, if interposed betwixt the sun and earth, will form a cloud; and, the same causes continuing to act, the cloud will produce

**Cloth

Cloud.

Cloud.

produce rain or snow. But though the separation of this latent heat in a certain degree is the immediate cause of the formation of clouds, the remote cause, or the changes produced in the atmosphere, whereby such a separation may be induced, are much more difficult to be discovered. In common observation, we see that vapour is most powerfully condensed by cold substances, such as metals, water, &c. But cold alone cannot in all cases cause the condensation of the atmospheric vapours, otherwise the nights behoved to be always foggy or cloudy, owing to the vapours, raised throughout the day by the heat of the sun, being condensed by the superior coldness of the night. Great rains will happen in very warm weather, when the union of the vapours with the atmosphere ought rather to be promoted than dissolved, if cold was the only agent in their condensation. The serenity of the atmosphere, also, in the most severe frosts, abundantly shews that some other cause besides mere heat or cold is concerned in the formation of clouds, and condensation of the atmospheric vapours.

2
Not always
owing to
cold.

3
Electricity
probably
concerned.

The electric fluid is now so generally admitted as an agent in all the great operations of nature, that it is no wonder to find the formation of clouds attributed to it. This hath accordingly been given by S. Beccaria as the cause of the formation of all clouds whatsoever, whether of thunder, rain, hail, or snow. The first, he thinks, are produced by a very great power of electricity, and the others by one more moderate. But though it is certain that all clouds, or even fogs and rain, are electrified in some degree, it still remains a question, whether the clouds are formed in consequence of the vapour whereof they are composed being first electrified, or whether they become electrified in consequence of its being first separated from the atmosphere, and in some measure condensed. This hath not yet, as far as we know, been ascertained by the experiments of Beccaria, or any other person, and indeed, notwithstanding the multitude of electrical discoveries that have lately been made, there seems to be little or no foundation for ascertaining it. Electricity is known to be in many cases a promoter of evaporation; but no experiments have yet been brought to prove, that electrified air parts with its moisture more readily than such as is not electrified; so that, till the properties of electrified air are farther investigated, it is impossible to lay down any rational theory of the formation of clouds upon this principle.

ten prodigi-
ously elec-
trified.

5
Terrible
destruction
by an elec-
trified cloud
in Java.

But whether the clouds are produced, *i. e.* the invisible vapours floating in the atmosphere condensed so as to become visible, by means of electricity, or not, it is certain that they do contain the electric fluid in prodigious and inconceivable quantities, and many very terrible and destructive phenomena have been occasioned by clouds very highly electrified. The most extraordinary instance of this kind, perhaps, on record, happened in the island of Java in the East Indies in August 1772. On the 11th of that month, at midnight, a bright cloud was observed covering a mountain in the district called *Cheribon*, and at the same time several reports were heard like those of a gun. The people who dwelt on the upper parts of the mountain not being able to fly fast enough, a great

part of the cloud, almost three leagues in circumference, detached itself under them, and was seen at a distance rising and falling like the waves of the sea, and emitting globes of fire so luminous, that the night became as clear as day. The effects of it were astonishing: every thing was destroyed for seven leagues round; the houses were demolished; plantations were buried in the earth; and 2140 people lost their lives, besides 1500 head of cattle, and a vast number of horses, goats, &c.

Another instance of a very destructive cloud, the electric qualities of which will at present scarcely be doubted, is related by Mr Brydson, in his tour through Malta. It appeared on the 29th of October 1757. About three quarters of an hour after midnight, there was seen to the south-west of the city of Melita, a great black cloud, which, as it approached, changed its colour, till at last it became like a flame of fire mixed with black smoke. A dreadful noise was heard on its approach, which alarmed the whole city. It passed over the port, and came first on an English ship, which in an instant was torn in pieces, and nothing left but the hull; part of the masts, sails, and cordage, were carried to a considerable distance along with the cloud. The small boats and fellogoes that fell in its way were all broken to pieces and sunk. The noise increased and became more frightful. A sentinel terrified at its approach ran into his box; but both he and it were lifted up and carried into the sea, where he perished. It then traversed a considerable part of the city, and laid in ruins almost every thing that stood in its way. Several houses were laid level with the ground, and it did not leave one steeple in its passage. The bells of some of them, together with the spires, were carried to a considerable distance; the roofs of the churches demolished and beat down, &c. It went off at the north-east point of the city, and demolishing the light-house, is said to have mounted up into the air with a frightful noise; and passed over the sea to Sicily, where it tore up some trees, and did other damage; but nothing considerable, as its fury had been mostly spent at Malta. The number of killed and wounded amounted to near 200; and the loss of shipping, &c. was very considerable. See HURRICANE, and WHIRLWIND.

of Malta.

The effects of thunder-storms, and the vast quantity of electricity collected in the clouds which produce these storms, are so well known, that it is superfluous to mention them. It appears, however, that even these clouds are not so highly electrified as to produce their fatal effects on those who are immersed in them. It is only the discharge of part of their electricity upon such bodies as are either not electrified at all, or not so highly electrified as the cloud, that does all the mischief. We have, however, only the following instance on record, of any person's being immersed in the body of a thunder-cloud. Professor Saussure, and young Mr Jakabert, when travelling over one of the high Alps, were caught among clouds of this kind; and to their astonishment found their bodies so full of electrical fire, that spontaneous flashes darted from their fingers with a crackling noise, and the same kind of sensation as when strongly electrified by art.

free from them, as Mr Brydon experienced in his journey up mount Aetna : but those which are most highly electrified descend lowly, their height being often not above seven or eight hundred yards above the ground ; nay, sometimes thunder-clouds appear actually to touch the ground with one of their edges * ; but the generality of clouds are suspended at the height of a mile, or little more, above the earth. Some, however, have imagined them to rise to a most incredible and extravagant height. Maignan of Tholouze, in his treatise of Perspective, p. 93, gives an account of an exceeding bright little cloud that appeared at midnight in the month of August, which spread itself almost as far as the zenith. He says that the same thing was also observed at Rome ; and from thence concludes, that the cloud was a collection of vapours raised beyond the projection of the earth's shadow, and of consequence illuminated by the beams of the sun. This, however, can by no means be credited ; and it is much more probable that this cloud owed its splendor to electricity, than to the reflection of the solar beams.

In the evenings after sun-set, and mornings before sun-rise, we often observe the clouds tinged with beautiful colours. They are mostly red ; sometimes orange, yellow, or purple ; more rarely bluish ; and seldom or ever green. The reason of this variety of colours, according to Sir Isaac Newton, is the different size of the globules into which the vapours are condensed. This is controverted by Mr Melville, who thinks that the clouds reflect the sun's light precisely as it is transmitted to them through the atmosphere. This reflects the most refrangible rays in the greatest quantity ; and therefore ought to transmit the least refrangible ones, red, orange, and yellow, to the clouds, which accordingly appear most usually of those colours. In this opinion he was greatly confirmed by observing, when he was in Switzerland, that the snowy summits of the Alps turned more and more reddish after sun-set, in the same manner as the clouds : and he imagines that the semi-transparency of the clouds, and the obliquity of their situation, tend to make the colours in them much more rich and copious than those on the tops of snowy mountains.

CLOVES, in botany. See CARYOPHYLLUS.

CLOVE-TREE, in botany. See CARYOPHYLLUS.

CLOVE, a term used in weights of wool. Seven pounds make a clove. In Elix, eight pounds of cheese and butter go to the clove.

CLOVIS I. was the real founder of the French monarchy. For he was the first conqueror of the several provinces of Gaul possessed before his time by the Romans, Germans and Goths : these he united to the then scanty dominions of France, removed the seat of government from Scissions to Paris, and made this the capital of his new kingdom. He died in 511, in the 46th year of his age, and 3rd of his reign. See (*Hist. of*) FRANCE.

CLOYNE, a city and bishop's see of Ireland, in the county of Cork, and province of Munster : W. Long. 8. o. N. Lat. 51. 40.

CLUE of a SAIL, the lower corner ; and hence

CLUE-Garnets, are a sort of tackles fastened to the clues, or lower corners of the main-fail, or fore-fail, to truss them up to the yard as occasion requires, which is usually termed *clueing up* the sails.

CLUE-Lines are for the same purpose as clue-garnets ; only that the latter are confined to the courtes, whereas the former are common to all the square-sails. See these ropes as represented in the article SHIP.

CLUNY, or CLUGNY, a celebrated abbey of Benedictine monks, in a city of that name ; being the head or chief of a congregation denominated from thence.

It is situated in the Maçonnois, a little province of France, on the river Grône ; and was founded by William duke of Berry and Aquitain ; or, as others say, by the abbot Bernon, supported by that duke, in the year 910.

This abbey was anciently so very spacious and magnificent, that in 1245, after the holding of the first council of Lyons, Pope Innocent IV. went to Cluny, accompanied with the 2 patriarchs of Antioch and Constantinople, 12 cardinals, 3 archbishops, 15 bishops, and a great number of abbots ; who were all entertained, without one of the monks being put out of their place : tho' S. Louis, Q. Blanche his mother, the duke of Artois his brother, and his sister, the emperor of Constantinople, the sons of the kings of Arragon and Castile, the duke of Burgundy, 6 counts, and a great number of lords, with all their retinues, were there at the same time.

Cluny, at its first erection, was put under the immediate protection of the apostolic see ; with express prohibition to all secular and ecclesiastical powers, to disturb the monks in the possession of their effects, or the election of their abbot. By this they pretended to be exempted from the jurisdiction of bishops ; which at length gave the hint to other abbeyes to insist on the same.

Cluny is the head of a very numerous and extensive congregation : in effect, it was the first congregation of divers monasteries united under one chief, so as only to constitute one body, or, as they call it, one order, that ever arose.

CLUPEA, or herring, in ichthyology, a genus belonging to the order of abdominales. The upper jaw is furnished with a serrated mytstache ; the branchiostegic membrane has eight rays ; a scaly serrated line runs along the belly from the head to the tail ; and the belly-fins have frequently nine rays. There are 11 species, viz.

1. The *harengus*, or common herring, has no spots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water ; whence the proverb arises, *As dead as a herring*. The meat is every where in great esteem, being fat, soft, and delicate ; especially if it is dressed as soon as caught, for then it is incomparably better than on the next day.

The herring was unknown to the ancients. Notwithstanding the words *ῥαδιν* and *μακρί*, are, by translators rendered *hake*, the characters given to those fish are common to such numbers of different species as render it impossible to say which they intended.

Herrings are found from the highest northern latitudes,

History of
the herring
fishery.

tudes, yet known as low as the northern coasts of France; and except one instance, brought by Dod, of a few being once taken in the bay of Tangier, none are ever found more southerly. They are met with in vast shoals on the coast of America, as low as Carolina. In Cheapeake-bay is an annual inundation of those fish, which cover the shore in such quantities as to become a nuisance. We find them again in the seas of Kamtschatka, and probably they reach Japan; for Kempter mentions, in his account of the fish of that country, some that are congenerous. The great winter rendezvous of the herring is within the Arctic Circle; there they continue for many months in order to recruit themselves after the fatigue of spawning; the seas within that space swarming with insect-food in a far greater degree than those of our warmer latitudes. This mighty army begins to put itself in motion in the spring: we distinguish this vast body by that name; for the word *herring* comes from the German *beer*, "an army," to express their numbers. They begin to appear off the Shetland isles in April and May; there are only the forerunners of the grand shoal which comes in June: and their appearance is marked by certain signs, by the numbers of birds, such as gannets and others, which follow to prey on them; but when the main body approaches, its breadth and depth is such as to alter the appearance of the very ocean. It is divided into distinct columns of five or six miles in length, and three or four in breadth, and they drive the water before them with a kind of rippling: sometimes they sink for the space of ten or fifteen minutes, and then rise again to the surface; and in fine weather reflect a variety of splendid colours like a field of the most precious gems; in which, or rather in a much more valuable, light should this stupendous gift of Providence be considered by the inhabitants of the British isles.

The first check this army meets in its march southward is from the Shetland isles, which divide it into two parts; one wing takes to the east, the other to the western shores of Great Britain, and fill every bay and creek with their numbers; others pass on towards Yarmouth, the great and ancient mart of herrings: they then pass through the British Channel, and after that, in a manner disappear. Those which take towards the west, after offering themselves to the Hebrides, where the great stationary fishery is, proceed to the north of Ireland, where they meet with a second interruption, and are obliged to make a second division: the one takes to the western side, and is scarce perceived, being soon lost in the immensity of the Atlantic; but the other, that passes into the Irish sea, rejoices and feeds the inhabitants of most of the coasts that border on it. These brigades, as we may call them, which are thus separated from the greater columns, are often capricious in their motions, and do not shew an invariable attachment to their haunts.

Were we inclined to consider this partial migration in a moral light, we might reflect with veneration and awe on the mighty power which originally impressed on this most useful body of his creatures; the instinct that directs and points out the course, that blesses and enriches these islands, which causes them, at certain and invariable times, to quit

the vast polar deeps, and offer themselves to our expecting fleets. That benevolent Being has never been known, from the earliest account of time, once to withdraw this blessing from the whole; though he often thinks proper to deny it to particulars, yet this partial failure (for which we see no natural reason) should fill us with the most exalted and grateful sense of his Providence for impressing such an invariable and general instinct on these fish towards a southward migration when the whole is to be benefited, and to withdraw it when only a minute part is to suffer.

This instinct was given them, that they might remove for the sake of depositing their spawn in warmer seas, that would mature and vivify it more assuredly than those of the frozen zone. It is not from defect of food that they set themselves in motion; for they come to us full of fat, and on their return are almost universally observed to be lean and miserable. What their food is near the Pole we are not yet informed; but in our seas they feed much on the *oviscus marinus*, a crustaceous insect, and sometimes on their own fry.

They are full of roe in the end of June, and continue in perfection till the beginning of winter, when they deposit their spawn. The young herrings begin to approach the shores in July and August, and are then from half an inch to two inches long: those in Yorkshire are called *herring file*. Though we have no particular authority for it, yet as very few young herrings are found in our seas during winter, it seems most certain that they must return to their parental haunts beneath the ice, to repair the vast destruction of their race during summer by me, fowl, and fish. Some of the old herrings continue on our coast the whole year: the Scarborough fishermen never put down their nets but they catch a few; but the numbers that remain are not worth comparison with those that return.

The herring-fishery is of great antiquity. The industrious Dutch first engaged in it about the year 1164; and they were in possession of it for several centuries: but at length its value became so justly to be known, that it gave rise to most obstinate and well-disputed wars between the English and them; but still their diligence and skill gives them a great advantage in that branch of trade. Our great stations are off the Shetland and Western isles, and off the coast of Norfolk, in which the Dutch also share. Yarmouth has been long famous for its herring-fair; that town is obliged by its charter to send to the sheriffs of Norwich, 100 herrings, to be made into 24 pies, by them to be delivered to the lord of the manor of East Carleton, who is to convey them to the king. The facetious Dr Fuller takes notice of the great repute the county of Norfolk was in for this fish, and, with his usual archness, styles a red-herring a *Norfolk capon*. In 1195, Dunwich in Suffolk accounted to the king for their yearly farm-rent L. 120, 1 merk, and 24,000 herrings; 12,000 for the monks of Ely, and 12,000 for those of Eye.

The Dutch are most extravagantly fond of this fish when it is pickled. A premium is given to the first bus that arrives in Holland with a lading of this their ambrosia, and a vast price given for each keg. There is as much joy among the inhabitants on its arrival, as

Clupea.

6
Pickling of
herrings,
when in-
vented.

the Egyptians shew on the first overflowing of the Nile. Flanders had the honour of inventing the art of pickling herrings. One William Beaulken of Beverlet, near Sluys, hit on this useful expedient: from him was derived the name *pickle*, which we borrow from the Dutch and German. Beaulken died in 1397. The emperor Charles V. held his memory in such veneration for the service he did to mankind, as to do his tomb the honour of a visit. It is very singular that most nations give the name of their favourite dish to the facetious attendant on every mountebank. Thus the Dutch call him *pickle herring*; the Italians, *macaroni*; the French, *jeau pottage*; the Germans, *hans wurst*, that is, *jack sausage*; and the English dignify him with the name of *jack pudding*.

7
Sprattus,
where
found.

2. The *sprattus* has 13 rays in the back fin. It is a native of the European seas, and has a great resemblance to the herring, only it is of a less size. They come into the river Thames below bridge in the beginning of November, and leave it in March; and are, during that season, a great relief to the poor of the capital. At Gravesend and at Yarmouth, they are cured like red-herrings: they are sometimes pickled, and are little inferior in flavour to the anchovy, but the bones will not dissolve like those of the latter.

7
Alofa, or
shad, where
found.

3. The *alofa*, or *shad*, has a forked snout, and black spots on the sides. According to Belonius and Hafselquist, this is a fish of passage in the Nile. The last fish, it is found in the Mediterranean near Smyrna, and on the coast of Egypt near Rosetto; and that in the months of December and January it ascends the Nile as high as Cairo, where the people stuff it with pot marjoram; and when dressed in that manner, it will very nearly intoxicate the eater. In Great Britain the Severn affords this fish in higher perfection than any other river. It makes its first appearance there in May, but in very warm seasons in April; for its arrival sooner or later depends much on the temper of the air. It continues in the river about two months, and then is succeeded by a variety which we shall have occasion to mention hereafter.

8
The finest
inhabit the
Severn.

The Severn shad is esteemed a very delicate fish about the time of its first appearance, especially in that part of the river that flows by Gloucester, where they are taken in nets, and usually sell dearer than salmon: some are sent to London, where the fish-mongers distinguish them from those of the Thames, by the French name *alofe*. Whether they spawn in this river and the Wye is not determined, for their fry has not yet been ascertained. The old fish come from the sea into the river in full roe. In the months of July and August, multitudes of bleak frequent the river near Gloucester; some of them are as big as a small herring, and these the fishermen erroneously suppose to be the fry of the shad. Numbers of these are taken near Gloucester, in those months only, but none of the emaciated shad are ever caught in their return.

The Thames shad does not frequent that river till the latter end of May or beginning of June, and is esteemed a very coarse and insipid sort of fish. The Severn shad is sometimes caught in the Thames, though rarely, and called *allis* (no doubt *alofe*, the French name) by the fishermen in that river. About the same time, and rather earlier, the variety called, near

9
Twaite de-
scribed.

Gloucester, the *twaite*, makes its appearance; and is taken in great numbers in the Severn, and is held in as great dispute as the shad of the Thames. The differences between each variety are as follows: the true shad weighs sometimes eight pounds; but their general size is from four to five. The *twaite*, on the contrary, weighs from half a pound to two pounds, which it never exceeds. The *twaite* differs from a shad only in having one or more round black spots on the sides: if only one, it is always near the gill; but commonly there are three or four, placed one under the other.

Clupea.

10
Anchovy
described.

4. The *encrascolus*, or *anchovy*, has its upper jaw longer than the under one, and is about three inches long. They are taken in vast quantities in the Mediterranean, and are brought over here pickled. The great fishery is at Georgia, a smallisle west of Leghorn.

The other species are, 5. The *atherinoides* has a shining line on each side, and small belly-fins. It is a native of Surinam. 6. The *thrilla* has 28 rays in the fin at the anus. It is found in the Indian ocean. 7. The *fima* has yellow fins, those of the belly being very small. The mouth is flat; the upper jaw is very short; the body is of a shining silver colour; and the fins are yellow. It is a native of Asia. 8. The *sternia* has no belly-fins, and the body is broad. It is a native of Surinam. 9. The *mystus* is shaped like a sword, and the fins at the anus are united. It is found in the Indian ocean. 10. The *tropica* has a wedge-like tail, and a white, broad, compressed body; and the tail is wedge-shaped. It is found at Ascension island. 11. The *sinensis* is very like the common herring, but broader. It has no teeth, and is a native of China.

CLUSIA, the BALSAM-TREE; a genus of the monœcia order, belonging to the polygamia class of plants. There are four species, all natives of America. The most remarkable is the *flava*. This is pretty common in the British American islands, where the trees grow to the height of 20 feet, and shoot out many branches on every side, furnished with thick, round, succulent leaves placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover. After the flowers are past, they are succeeded by oval fruit. From every part of these trees there exudes a kind of turpentine, which is called in the West Indies *hog-gum*; because they say, that when any of the wild hogs are wounded, they repair to these trees, and rub their wounded parts against the stem till they have anointed themselves with this turpentine, which heals their wounds. These plants are very tender, and in this country must be kept constantly in a stove; and sparingly watered, especially in winter; for they naturally grow in those parts of the islands where it seldom rains, and consequently cannot bear much moisture. They may be propagated from cuttings, which must be laid to dry for a fortnight or three weeks, that the wounded parts may be healed over, otherwise they will rot. The best time for planting these cuttings is in July, that they may be well rooted before the cold weather comes on in autumn.

CLUTIA, a genus of the gynandria order, belonging to the dioecia class of plants. There are three species,

Clavier
Clyfter.

species, all of them natives of warm climates. They are evergreen shrubby plants, rising six or eight feet high, garnished with simple leaves, and greenish-white quinquepetalous flowers. They are propagated by cuttings in spring or summer, planting them in pots of light earth, plunged in a hot-bed. The plants must always be kept in a stove.

CLUVIER (Philip), in Latin *Cluverius*, a celebrated geographer, born at Dantzic in 1580. He travelled into Poland, Germany, and the Netherlands, in order to study law; but, being at Leyden, Joseph Scaliger persuaded him to give way to his genius for geography. Clavier followed his advice, and for this purpose visited the greatest part of the European states. He was well versed in many languages; and wherever he went, obtained illustrious friends and protectors. At his return to Leyden, he taught there with great applause; and died in 1623, aged 43. He wrote, 1. *De tribus Rhein alevi*. 2. *Germania antiqua*. 3. *Sicilia antiqua*. 4. *Italia antiqua*. 5. *Introductio in universam Geographiam*. All justly esteemed.

CLYDE, a river in Scotland, which, arising in Annandale, runs north-west by Lanerk, Hamilton, and Glasgow, and falls into the river Clyde, over against the isle of Bute. Anciently this river was renowned for producing gold dust and lapis lazuli, as it still is for the rich lead mines belonging to the Earl of Hop-ton. These are said to have been discovered by Sir Bevis Bulmer, in the beginning of the last century, while he was endeavouring to find a gold mine.

CLYMENE, in fabulous history, the daughter of Oceanus; who, being beloved by Apollo, he had by her Phæton, Lampatia, Egle, and Phebe. See PHÆTON.

CLYPEOLA, TREACLE-MUSTARD; a genus of the filiculosa order, belonging to the tetradynamia class of plants. There are two species, both natives of France, Italy, and the warm parts of Europe, but hardly enough to bear the winters in this country. One of them is an annual, and the other a perennial plant; both are low and herbaceous, bearing spikes of white flowers. They are propagated by seeds, which should be sown in autumn where they are to remain.

CLYSSUS, an extract prepared, not from one, but several bodies mixt together: and, among the moderns, the term is applied to several extracts prepared from the same body, and then mixed together. See CHEMISTRY, n° 221.

CLYSTER, is a liquid remedy, to be injected chiefly at the anus into the larger intestines. It is usually administered by the bladder of a hog, sheep, or ox, perforated at each end, and having at one of the apertures an ivory pipe fastened with pack-thread. But the French, and sometimes the Dutch, use a pewter syringe, by which the liquor may be drawn in with more ease and expedition than in the bladder, and likewise more forcibly expelled into the large intestines. This remedy should never be administered either too hot or too cold, but tepid; for either of the former will be injurious to the bowels.

Clysters are sometimes used to nourish and support a patient who can swallow little or no aliment, by reason of some impediment in the organs of deglutition;

in which case they may be made of broth, milk, ale, and decoctions of barley and oats with wine. The English introduced a new kind of clyster, made of the smoke of tobacco, which has been used by several other nations, and appears to be of considerable efficacy when other clysters prove ineffectual, and particularly in the iliac passion, in the *hernia incarcerata*, and for the recovery of drowned persons.

CLYTEMNESTRA, in fabulous history, the daughter of Jupiter and Leda. She married Agamemnon; but while that prince was at the siege of Troy, she had an amorous intrigue with Ægisthus, whom she engaged to murder Agamemnon at his return to his dominions. Her son Orestes, however, revenged the death of his father by killing Ægisthus, with his mother Clytemnestra; but was afterwards haunted by the Furies as long as he lived.

CNEORUM, WIDOW-WAIL; a genus of the monogynia order, belonging to the triandria class of plants. There is but one species, a little evergreen, and very ornamental shrub, adorned with simple leaves, and tripetalous flowers of a pale yellow colour. It is propagated from seeds, and requires no other care than to be kept free from weeds.

CNICUS, BLESSED-THISTLE; a genus of the polygama æqualis order, belonging to the syngenesia class of plants. There are seven species, of which the only remarkable one is that used in medicine under the name of *cardus benedictus*. This is an annual plant cultivated in gardens: it flowers in June and July, and perfects its seeds in autumn. For medical purposes the plant should be gathered when in flower, dried in the shade, and kept in a very dry airy place, to prevent its rotting or growing mouldy, which it is very apt to do. The leaves have a penetrating bitter taste, not very strong or durable, accompanied with an ungrateful flavour, which they are in a great measure freed from by keeping. Water extracts in a little time, even without heat, the lighter and more grateful parts of this plant; if the digestion is continued for some hours, the disagreeable parts are taken up; a strong decoction is very nauseous and offensive to the stomach. Rectified spirit gains a very pleasant bitter taste, which remains uninjured in the extract. The virtues of this plant are little known in the present practice. The nauseous decoction is sometimes used to provoke vomiting; and a strong infusion to promote the operation of other emetics. But this elegant bitter, when freed from the offensive parts of the herb, may be advantageously applied to other purposes. Dr Lewis informs us, that he has experienced excellent effects from a light infusion of *cardus* in loss of appetite, where the stomach was injured by irregularities. A stronger infusion made in cold or warm water, if drunk freely, and the patient kept warm, occasions a plentiful sweat, and promotes all the secretions in general. The feeds of the plant are also considerably bitter, and have sometimes been used with the same intention as the leaves.

COACH, a vehicle for commodious travelling, suspended on leathers, and moved on wheels. In England, and throughout Europe, the coaches are drawn by horses, except in Spain, where they use mules. In a part of the east, especially the dominions of the Great

Clytemne-
stra
Coach.

Coach.

Coach
|
Coal.

Mogul, their coaches are drawn by oxen. In Denmark they sometimes yoke rein-deer in their coaches; though rather for curiosity than use. The coachman is ordinarily placed on a seat raised before the body of the coach. But the Spanish policy has displaced him in that country by a royal ordonnance; on occasion of the duke d'Olivares, who found that a very important secret, whereon he had conferred in his coach, had been overheard and revealed by his coachman: since that time the place of the Spanish coachman is the same with that of the French stage-coachman, and our postillion, *viz.* on the first horse on the left.

The invention of coaches is owing to the French: yet are not coaches of any great antiquity, even in France; scarce reaching beyond the reign of their Francis I. Their use, at their first rise, was only for the country: and authors observe, as a thing very singular, that there were at first no more than two coaches in Paris; the one that of the queen, and the other that of Diana natural daughter of Henry II. The first courtier who had one was Jean de Laval de Bois Dauphin; whose enormous bulk disabled him from travelling on horseback. One may hence judge how much variety, luxury, and idleness, have grown upon our hands in later days; there being now computed in that same city no less than 15,000 coaches.

Coaches have had the fate of all other inventions, to be brought by degrees to their perfection; at present they seem to want nothing, either with regard to ease or magnificence. Louis XIV. of France made several sumptuary laws for restraining the excessive richness of coaches, prohibiting the use of gold, silver, &c. therein; but they have had the fate to be neglected.

Coaches may be divided into two kinds; those that have iron bows, or necks, and those that have not: both the one and the other have two principal parts, the body and the train or carriage. The body is that part where the passengers are disposed; and the carriage that which sustains the body, and to which the wheels are fastened, that give motion to the whole machine. Coaches, with regard to their structure, are divided into *coaches* properly so called, *chariots*, *calashes*, &c.

Hackney-COACHES, those exposed to hire, in the streets of London, and some other great cities, at rates fixed by authority.

Eight hundred hackney-coaches, and 200 chairs, are allowed in London and Westminster; which are to be licensed by commissioners, and to pay a duty to the crown. They are all numbered, having their numbers engraven on tin plates fixed on the coach doors. Their fares or rates are fixed by act of parliament; 10s. for a whole day of 12 hours, for a single hour 1s. 6d.; for every hour after the first 1s. At these rates they are obliged to carry passengers any where within 10 miles of London.

Stage-COACHES, are those appointed for the conveyance of travellers from one city or town to another. The masters of stage-coaches are not liable to an action for things lost by their coachmen, who have money given them to carry the goods, unless where such master takes a price for the same.

COACH, or *Couch*, is also a sort of chamber or apartment in a large ship of war near the stern. The floor of it is formed by the almost part of the quarter-deck, and the roof of it by the poop: it is generally the habitation of the captain.

COADUNATE, in botany, an order of plants in the *fragmenta methodi naturalis* of Linnæus, in which he has these genera, *viz.* annona, liriodendrum, magnolia, uvaria, michelia, thea. See BOTANY, p. 1216. Vol. II.

COAGULATION, in chemistry, is performed by six different agents; and by each of these in several different manners. 1. It is performed with water, by congealing, crystallizing, and precipitating, as in the mercurius vitæ, and some other preparations. 2. With oil, which, by the force of fire, unites with sulphur, salts, and metals. 3. With alcohol, upon the spirit of sal ammoniac, the white of eggs, the serum of the blood, &c. 4. With acid and alkali growing solid together, as in the tartarum vitriolatum. 5. With fixed alkali, as in milk. And, 6. With acid salts; as in milk, serum, and the whites of eggs.

COAGULUM, is the same with what in English we call *runnet*, or rather the curd formed thereby.

COAKS. For the exciting of intense heats, as for the smelting of iron ore, and for operations where the acid and oily particles would be detrimental, as the drying of malt, fossil-coals are previously charred, or reduced to *coaks*; that is, they are made to undergo an operation similar to that by which charcoal is made. By this operation coals are deprived of their phlegm, their acid liquor, and part of their fluid oil. Coaks, therefore, consist of the two most fixed constituent parts, the heavy oil and the earth, together with the acid concrete salt, which, though volatile, is dissolved by the oil and the earth.

COAL, among chemists, signifies any substance containing oil, which has been exposed to the fire in close vessels, so that all its volatile principles are expelled, and that it can sustain a red heat without further decomposition. Coal is commonly solid, black, very dry, and considerably hard. The specific character of perfect coal is its capacity of burning with access of air, while it becomes red-hot and sparkles, sometimes with a sensible flame which gives little light, with no smoke or foot capable of blackening white bodies.

Coal is capable of communicating its inflammable principle, either to the vitriolic acid with which it forms sulphur; or to the nitrous acid contained in nitre, which it inflames; or to metallic earths, which it reduces into metals. But the phlogiston cannot pass from coal to form these new combinations without the assistance of red-heat. Coal seems to be an unalterable compound in every instance but those mentioned, of burning in the open air, and of communicating its phlogiston to other bodies: for it may be exposed in close vessels to the most violent and long continued fire without suffering the least decomposition. No disposition to fuse, nor any diminution of weight, can be perceived. It is a substance exceedingly fixed, and perhaps the most refractory in nature. It resists the action of the most powerful menstrua, liver of sulphur alone excepted. Coal is evidently a result of the decomposition of the compound bodies from which it is obtained.

Coal.

obtained. It consists of the greatest part of the earthy principle of these compound bodies, with which a part of the saline principles, and some of the phlogiston of the decomposed oil, are fixed and combined very intimately. Coal can never be formed but by the phlogiston of a body which has been in an oily state: hence it cannot be formed by sulphur, phosphorus, metals, nor by any other substance the phlogiston of which is not in an oily state. Also every oily matter treated with fire in close vessels, furnishes true coal; so that whenever a charry residuum is left, we may be certain that the substance employed in the operation contained oil. Lastly, the inflammable principle of coal, although it proceeds from oil, certainly is not oil; but pure phlogiston; since coal added to vitriolic acid can form sulphur, to phosphoric acid can form phosphorus, &c. and since oil can produce none of these effects till it has been decomposed and reduced to the state of coal. Besides, the phenomena accompanying the burning of coal are different from those which happen when oily substances are burnt. The flame of charcoal is not so bright as that of oil, and produces no flame or foot.

All the phlogiston of coal is not burnt in the open air, particularly when the combustion is slow. One part of it exhales without decomposition, and forms a vapour, or an invisible and insensible gas. This vapour, (which is, or at least contains a great deal of, fixed air) is found to be very pernicious, and to affect the animal system in such a manner as to occasion death in a very short time. For this reason it is dangerous to remain in a close place, where charcoal or any other sort of coal is burnt. Persons struck by this vapour are stunned, faint, suffer a violent headache, and fall down senseless and motionless. The best method of recovering them is by exposure to the open air, and by making them swallow vinegar, and breathe its steam.

Amongst coals, some differences are observable, which proceed from the difference of the bodies from which they are made: some coals, particularly, are more combustible than others. This combustibility seems to depend on the greater or less quantity of saline principle they contain; that is, the more of the saline principle it contains, the more easily it decomposes and burns. For example, coals made of plants and wood containing much saline matter capable of fixing it, the ashes of which contain much alkaline salt, burn vigorously and produce much heat; whereas the coals of animal matters, the saline principles of which are volatile, and cannot be fixed but in small quantity, and the ashes of which contain little or no salt, are scarcely at all combustible. For they not only do not kindle so easily as charcoal does, nor ever burn alone, but they cannot be reduced to ashes, without very great trouble, even when the most effectual methods are used to facilitate the combustion. The coal of bullocks blood has been kept for six hours very red in a shallow crucible, surrounded with burning charcoal, and constantly stirred all the time, that it might be totally exposed to the air; yet could it not be reduced to white, or even grey, ashes. It still remained very black, and full of phlogiston. The coals of pure oils are of concrete oily substances and foot, which is a kind of coal raised during inflammation, are as difficultly reduced to ashes

as animal coals. These coals contain very little saline matter; and their ashes yield no alkali. The coals which are so difficultly burnt, are also less capable of inflaming with nitre than others more combustible; and some of them even in a great measure resist the action of nitre.

Cannel-Coal. See AMPELITES.

Fossil Coal, or Pit-coal. See LITHANTHRAX and COALERY.

Coal-Fish. See GADUS.

Coal-Mine. See COALERY.—Maliciously setting fire to coal-mines is felony, by stat. 10 Geo. II. c. 32. § 6.

Small-Coal, a sort of charcoal prepared from the spray and brushwood stripped off from the branches of coppice wood, sometimes bound in bairns for that purpose, and sometimes charred without binding, in which case it is called "coming it together."

COALERY, COLLIERY, or COLLIERY, a coal-History of coals, work, or place where coals are dug. See LITHANTHRAX.

It is generally agreed, that our cannel-coal* is the lapis ampetites of the Romans; though it seems to have been used by them only for making toys, bracelets, &c. But of that common fuel which we denominate *coals*, the native Romans were entirely ignorant. It is certain that they are not, as some have imagined, the lapis obsidianus of Pliny†, about which there have been great disputes: nor the GAGATES, or JET, which others, again, have taken for the *lapis obsidianus*; though the lightness and texture show plainly that it is not either stone or coal. In fact, there are no beds of it in the compass of Italy. The great line of that fuel seems to sweep away round the globe, from north-east to south-west; not ranging at a distance even from the south-easterly parts of our island, as is generally imagined, but actually visiting Brabant and France, and yet avoiding Italy.

But the primeval Britons appear to have used it. And in the precincts of Manchester particularly, which are furnished with an inexhaustible abundance of it, they could not have remained unapprised of the agreeable combustible around them. The currents there frequently bring down fragments of coal from the mountains; and in the long and winding course of them through the parish, the Britons would soon mark the shining stones in the channels; and by the aid of accident, or the force of reflection, find out the utility of them. But we can advance still nearer to a certainty. Several pieces of coal were discovered some years ago in the sand under the Roman way to Ribchester, when both were dug up at the construction of a house in Quay-street. The number of pieces, several of them as large as eggs, was not less than 40; and a quantity of slack was dug up with them. These circumstances show the coals to have been lodged upon the spot, before the road of the Romans covered it. That ground being in the neighbourhood of *Mancunium*‡, the Britons had there deposited a quantity of coals, probably for the use of the garrison; and many of the smaller fragments, and some of the slack, were buried in the sand upon which they were laid. And that the Britons in general were acquainted with this fuel, is evident from its appellation amongst us at present, which is not Saxon, but British; and subsists among

Whitaker's History of Manchester.

‡ i. e. "the place of tents." An ancient British town, the site of which was the present Castlefield at Manchester.

Coalery. among the Irish in their *O gual*, and among the Cornish in their *kolan*, to this day. Coalery.

The extensive beds of fuel, therefore, with which the kingdom of England and the precincts of Manchester are so happily stored, were first noticed by the skill, and first opened by the labour, of the Britons; and some time before the arrival of the Romans among us. And the nearer quarries in the confines of Bradford, Newton, and Manchester, would naturally attract the notice, and invite the inquiries, of the Britons, before any others. The current of the Medlock, which washes the sides of them, would bring down specimens of the riches within, lodge many of them about the Castlefield, and allure the Britons successively to a collection of the one and a search after the other.

But, even for ages after the discovery, wood continued to compose the general firing of the nation. In 852, a grant was made of some lands by the abbey of Peterborough, under the reservation of certain boons and payments in kind to the monastery; as, one night's entertainment; 10 vessels of Welsh and two of common ale; 60 cart-loads of wood; and 12 of pit-coal; where we see the quantity of coal was only one cart-load to five of wood. The latter naturally continued the principal article of our fuel as long as the forests and thickets presented themselves so ready to the hand: and such it continued till a very late period. The first public notice of the former is mentioned by Mr Hume to have been in the time of Henry III. who in the year 1272, granted a charter to the town of Newcastle, giving the inhabitants a license to dig coals: and the first statute relating to this article was the 9 Henry V. c. 10. ordaining all keels in the port of Newcastle to be measured by commissioners, before carriage of coals, on pain of forfeiture. They were not brought into common use till the reign of Charles I.; and were then sold for about 17s. a chaldron. In some years after the restoration, there were about 200,000 chaldrons burnt in London; in 1670, about 270,000 chaldrons; and at the revolution, upwards of 300,000 chaldrons; and at present, full 600,000 are annually consumed there. There is, besides, an immense consumption in other parts of Britain, and in Ireland. In Scotland, they supply their own consumption, and also export. In Ireland, though they have coal, yet they take annually to the value of 30,000*l.* from England, and 12,000*l.* from Scotland.

There are several other countries in Europe which possess considerable coal-mines; as France, Liege, Germany, and Sweden. Also on the other side of the Atlantic ocean, there has been coal discovered, and wrought; in Newfoundland, Cape Breton, Canada, and some of the New-England provinces. But in all these countries, the coal is of a quality much inferior to the British, and entirely unfit to be used in many manufactures; so that they are obliged to import great quantities from Britain for the use of their manufactures of iron, &c.

Our inland coal-trade, that is, carrying coals from Newcastle, Sunderland, Blith, and other adjacent places in the north of England, as also from the frith of Edinburgh in Scotland, and other places thereabouts, to the city of London, and to the port-towns on the coast all the way, as well on this side of Newcastle,

north, as up the channel as high as Portsmouth west, is a prodigious article, and employs abundance of shipping and seamen; in so much that, in a time of urgent necessity, the coalery navigation alone has been able to supply the government with a body of seamen for the royal navy, able to man a considerable fleet at a very short warning, and that without difficulty, when no other branch of trade would do the like. Likewise the Whitehaven coaleries in Cumberland belonging to Sir James Lowther, furnish several counties in Ireland with coals, and constantly employ upwards of 2000 seamen; which also is a noble nursery for the navy of this kingdom. And not only do the pit-coals sufficiently supply all the ports, but, by means of those ports and the navigable rivers, all the adjacent counties very far inland.

In short, coals, though not an exclusive, yet may, with propriety, be styled a peculiar blessing to Britain, with their great plenty, their acknowledged excellence, and their being found in such places as are conveniently situated for exportation. Nor is there any danger of the export-trade being lessened even by the several duties that have been laid upon them; for the foreign consunt being founded in necessity with regard to manufactures, and in economy where they are used for convenience, (wood and turf being dearer than coals with the duty), we need be in no fear of the markets declining. There is as little room to be alarmed from an apprehension of their being exhausted, as the present works are capable of supplying us for a long series of years, and there are many other mines ready to be opened when these shall fail. Besides, there are known to be coals in many parts of the three kingdoms, which hitherto they have had no encouragement to work.

Besides the value of this commodity as a convenience of life, as an article of commerce, and as giving rise to a nursery of seamen for the increase of the marine; other important advantages deserve to be noticed. Coals are in many respects, and in a very high degree, useful to the landed interest; not only by raising exceedingly the real value, and of course the purchase, of those lands in which they are found, and those through which it is necessary to pass * from the works to the places where they are embarked; but from the general improvements they have occasioned; so that very few counties are now better cultivated than Northumberland, and the same effects they have had in a greater or less degree in other places. Thousands of laborious people are employed in and about the mines; thousands more in conveying them to the ports, and on board the ships; to say nothing of those that draw their subsistence from the carriage of them by land to supply families, &c. There are also great numbers that live in a superior station; as stewards, directors, factors, agents, book-keepers, &c. To these we may add the extraordinary encouragement given to ingenious artists who have invented, and the numerous workmen continually employed about those several curious and costly machines which, for a variety of purposes in this business, are in continual use, and of course in continual wear: we may join to these the multitudes that obtain their living from the many manufactures in which they are employed, and which could

could not be carried on but by the help and cheapness of coals. Lastly, the produce of coals exported, which amounts to a very considerable sum, besides being profitable to the owners, merchants, and mariners, is so much clear gain to the nation.

It might be expected, that a trade so beneficial to individuals, and to the nation in general, and which has been gradually increasing for several centuries past, would have been advanced by this time to very great perfection, and reduced to a regular system. But, in one very essential respect, it is found to be quite otherwise. The art of working coal-mines in the most profitable manner is indeed highly improved: but the fundamental of the art, that of searching for and discovering coal in any district of country where it has not yet been found, has never, that we know of, been treated in a systematic manner. The reader, therefore, will not be displeased to find this defect supplied in the course of the present article, together with a detail of all the other operations in the business of coaleries.

The terrestrial matters which compose the solid parts of the earth are disposed in strata, beds, or layers, the under surface of one bearing against, or lying upon, the upper surface of that below it; which last bears or lies on the next below in the same manner.

These strata consist of very different kinds of matter, such as free-stone, lime-stone, metal-stone, or whin-stone, coal, &c. as will be particularly specified in the sequel.

Some of these strata are of a considerable thickness, being often found from 100 to 200 feet or upwards, nearly of the same kind of matter from the superior to the inferior surface; and others are found of the least thickness imaginable, one inch or less.

All these strata are divided or parted from each other laterally, either by their even, smooth, polished surfaces, with very thin lamina of soft or dusty matter betwixt them, called the *parting*, which renders them easy to separate; or else only by the surfaces closely conjoined to each other, without any visible matter interposed betwixt them; yet the different substance of each stratum is not in the least intermixed, though sometimes they adhere so strongly together, that it is very difficult to part or disjoin them: in this last case they are said to have a *bad parting*.

Besides this principal division or parting laterally, there are, in some strata, secondary divisions or partings also laterally, separating, or approaching towards a separation, of the same stratum, into parts of different thicknesses, nearly parallel to each other, in the same manner as the principal partings divide the different strata from each other: but these secondary ones are not so strong or visible, nor make so effectual a parting, as the principal ones do; and are only met with in such strata, as are not of an uniform hardness, texture, or colour, from the upper to the under surface.

There are other divisions or partings, called *backs*, in almost every stratum, which cross the former lateral ones longitudinally, and cut the whole stratum through its two surfaces into long rhomboidal figures. These again are crossed by others called *cutters*, running either in an oblique or perpendicular direction to the last mentioned backs, and also cut the stratum

through its two surfaces. Both these backs and cutters generally extend from the upper or superior stratum down through several of the lower ones; so that these backs and cutters, together with the lateral partings before mentioned, divide every stratum into innumerable cubic, prismatic, and rhomboidal figures, according to the thickness of the stratum, and the position and number of the backs and cutters. They sometimes have a kind of thin partition of dusty or soft matter in them, and sometimes none, like the first mentioned partings; but the softer kind of strata generally have more backs and cutters than the harder kind, and they do not extend or penetrate through the others.

To explain this a little further, let A, B, C, D, E, F, G, (fig. 1.) represent the principal partings before mentioned; or the upper and under surfaces of any stratum; then a, b, c, d, e, f, g will represent the secondary lateral partings nearly parallel to the principal ones; g, h, i, k, l, m , the longitudinal partings called *backs*; n, o, p, q, r, s , the cross partings called *cutters*, crossing the last mentioned ones either obliquely or perpendicularly.

In all places where the strata lie regular, they are divided and subdivided in the manner above mentioned; and sometimes in this manner extend through a pretty large district of country: though it is often otherwise; for their regularity is frequently interrupted, and the strata broken and disordered, by sundry chafms, breaches, or fissures, which are differently denominated according to their various dimensions, and the matters with which they are filled, viz. dikes, ditches, and troubles, which shall be explained in order.

Dikes are the largest kind of fissures. They seem to be nothing but a crack or breach of the solid strata, occasioned by one part of them being broken away and fallen from the other. They generally run in a straight line for a considerable length, and penetrate from the surface to the greatest depth ever yet tried, in a direction sometimes perpendicular to the horizon, and sometimes obliquely; the same kind of strata are found lying upon each other in the same order, but the whole of them greatly elevated or depressed, on the one side of the dike as on the other. These fissures are sometimes two or three feet wide, and sometimes many fathoms. If the fissure or dike be of any considerable width, it is generally filled with heterogeneous matter, different from that of the solid strata on each side of it. It is sometimes found filled with clay, gravel, or sand; sometimes with a confused mass of different kinds of stone lying edgewise; and at other times with a solid body of free-stone, or even whin-stone. When the fissure is of no great width, as suppose two or three feet only, it is then usually found filled with a confused mixture of the different matters which compose the adjoining strata, consolidated into one mass. If a dike runs or stretches north and south, and the same kind of strata are found on the east side of the dike, in a situation with respect to the horizon 10 or 20 fathoms lower than on the other side, it is then said to be a *dip-dike* or *downcast-dike* of 10 or 20 fathoms to the eastward;—or counting from the east side, it is then said to be a *rise-like* or *upcast* of so many fathoms westward. If the strata on one side are not much higher or lower with respect to the horizontal

Plate
LXXXI.

5
Dikes.

horizontal

Coalery. rizontal line, than those on the other, but only broken off and removed to a certain distance, it is then said to be a dike of so many fathoms thick; and from the matter contained between the two sides of the fissure or dike, it is denominated a *clay-dike*, *stone-dike*, &c.

6
Hitches.

A *hitch* is only a dike or fissure of a smaller degree, by which the strata on one side are not elevated or separated from those on the other side above one fathom. These hitches are denominated in the same manner as dikes, according to the number of feet they elevate or depress the strata.

There are dikes (though they are not often met with in the coal-countries) whose cavities are filled with sparr, the ores of iron, lead, vitriol, or other metallic or mineral matters; and it is pretty well known, that all metallic veins are nothing else than what in the coal-countries are called *dikes*.

The strata are generally found lying upon each other in the same order on one side of the dike as on the other, as mentioned above, and nearly of the same thickness, appearing to have been originally a continuation of the same regular strata, and the dike only a breach by some later accident, perpendicularly or obliquely down through them by which one part is removed to a small distance, and depressed to a lower situation than the other. But this is not the only alteration made in the strata by dikes; for generally to a considerable distance on each side of the dike, all the strata are in a kind of shattered condition, very tender, easily pervious to water, and debased greatly in their quality, and their inclination to the horizon often altered.

7
Troubles.

Troubles may be denominated dikes of the smallest degree; for they are not a real breach, but only an approach towards it which has not taken a full effect. The strata are generally altered by a trouble from their regular sit to a different position. When the regular course of the strata is nearly level, a trouble will cause a sudden and considerable ascent or descent: where they have, in their regular situation, a certain degree of ascent or descent, a trouble either increaseth it or alters it to a contrary position: and a trouble has these effects upon the strata in common with dikes, that it greatly debaseth them from their original quality; the partings are separated; the backs and cutters disjoined, and their regularity disordered; the original cubic and prismatic figures, of which the strata were composed, are broken, and the dislocation filled with heterogeneous matter; and the whole strata are reduced to a softer and more friable state.

8
Dip and
rise of the
strata.

The strata are seldom or never found to lie in a true horizontal situation; but generally have an inclination or descent, called the *dip*, to some particular part of the horizon. If this inclination be to the eastward, it is called an *east dip*, and a *west rise*; and according to the point of the compass to which the dip inclines, it is denominated, and the ascent or rise is to the contrary point. This inclination or dip of the strata is found to hold every where. In some places, it varies very little from the level; in others, very considerably; and in some so much, as to be nearly in a perpendicular direction: but, whatever degree of inclination the strata have to the horizon, if not interrupted by dikes, hitches, or troubles, they are always

found to lie in the first regular manner mentioned. They generally continue upon one uniform dip until they are broken or disordered by a dike, hitch, or trouble, by which the dip is often altered, sometimes to a different part of the horizon, and often to an opposite point; so that on one side of a dike, hitch, or trouble, if the strata have an east dip, on the other side they may have an east rise, which is a west dip; and in general, any considerable alteration in the dip is never met with, but what is occasioned by the circumstances last mentioned.

To illustrate what has been said, see fig. 2. where Plate LXXXI.
a b c d, &c. represents a course of strata lying upon each other, having a certain inclination to the horizon. *A B*, is a downcast-dike, which depresseth the strata obliquely to *e f g h*, &c. lying upon each other in the same order, but altered in their inclination to the horizon. *C D* represents a clay or free-stone dike, where the strata are neither elevated nor depressed, but only broken off and removed to a certain distance. *E F*, represents a hitch, which breaks off and depresseth the strata only a little, but alters their inclination to the horizon. *G H*, represents a trouble, where the strata on one side are not entirely broken off from those on the other, but only in a crushed and irregular situation.

As some particular strata are found at some times to increase, and at other times to diminish, in their thickness, whilst others remain the same, consequently they cannot be all parallel; yet this increase and diminution in their thickness comes on very gradually.

The strata are not found disposed in the earth according to their specific gravities: for we often find strata of very dense matter near the surface; and perhaps at 50 or even 100 fathoms beneath, we meet with strata of not half the specific gravity of the first. A stratum of iron ore is very often found above one of coal, though the former has twice the gravity of the latter; and, in short, there is such an absolute uncertainty in forming any judgment of the disposition of the strata from their specific gravities, that it cannot in the least be relied upon.

It has been imagined by many, that hills and valleys are occasioned by those breaches in the strata before mentioned called *dikes*; but this is contradicted by experience. If it was so, we should meet with dikes at the skirts of the hills, and by the sides of valleys, and the sea-shore; but instead of that, we generally find the strata lying as uniformly regular under hills and valleys, and beneath the bottom of the sea (as far as has been yet tried), as in the most campaign countries. It may happen, indeed, that a dike is met with in some of these places; but that being only a casual circumstance, can never be admitted as a general cause. Whatever irregularities are occasioned in the solid strata by dikes, or other breaches, are commonly covered over and evened by those beds of gravel, clay, sand or soil, which lie uppermost, and form the outward surface of the earth. Wherever these softer matters have been carried off, or removed by accident, as on the tops of hills and the sides of valleys, there the solid strata are exposed, and the dip and rise and other circumstances of them may be examined; but no certain conclusions can be drawn, merely

merely from the unevenness and inequalities of the outward surface.

The preceding observations, upon the general disposition of the solid strata, are equally applicable to the strata of coal as to those of stone or other matter.

9
Description
of the strata
connected
with
coal.

We shall next give an account of the several strata of coal, and of stone and other matters, which are usually connected with coal, and are found to have a particular affinity with it: and, for the sake of distinction, shall arrange them into six principal classes, which will include all the varieties of strata that have been found to occur in all those districts of country both in Scotland and England where coal abounds.

1. *Of Whin-stone.*] The strata of what is denominated whin-stone are the hardest of all others; the angular pieces of it will cut glass; it is of a very coarse texture, and when broke across the grain exhibits the appearance of large grains of sands half vitrified; it can scarcely be wrought, or broke in pieces, by common tools without the assistance of gun-powder; each stratum is commonly homogeneous in substance and colour, and cracked in the rock to a great depth. The most common colours of these strata are black or dark blue, yet there are others of it ash-coloured and light brown. Their thickness in all the coal countries is but inconsiderable, from six or five feet down to a few inches; and it is only in a few places they are met with of these thicknesses. In the air it decays a little, leaving a brown powder; and in the fire it cracks, and turns reddish brown. Limestone, and what is called *bastard limestone*, is sometimes, tho' rarely, met with in coaleries. It is a well known stone; but from its resemblance in hardness and colour is often mistaken for a kind of whin. Sometimes, particularly in hilly countries, the solid matter next the surface is found to be a kind of soft or rotten whin;—but it may be noted, that this is only a mass of heterogeneous matter disposed upon the regular strata; and that beneath this, all the strata are generally found in as regular an order as where this heterogeneous matter does not occur.

2. *Of Poft-stone.*] This is a free stone of the hardest kind, and next to the limestone with respect to hardness and solidity. It is of a very fine texture; and when broken appears as if composed of the finest sand. It is commonly found in a homogeneous mass, tho' variegated in colour; and, from its hardness, is not liable to injury from being exposed to the weather. Of this kind of stone there are four varieties, which may be distinguished by their colour: the most common is white poft, which in appearance is like Portland stone, but considerably harder; it is sometimes variegated with streaks or spots of brown, red, or black.

Grey poft is also very common; it appears like a mixture of fine black and white sand: it is often variegated with brown and black streaks, the last mentioned appear like small clouds composed of particles of coal.

Brown or yellow poft is often met with of different degrees of colour; most commonly of the colour of light ochre or yellow sand: it is as hard as the rest, and sometimes variegated with white and black streaks.

Red poft is generally of a dull red colour: this is

but rarely met with; it is often streaked with white or black.

All these lie in strata of different thicknesses; but commonly thicker than any other strata whatever: they are separated from each other, and from other kind of strata, by partings of coal, sand, or soft matter of different colours which are very distinguishable.

3. *Of Sand-stone.*] This is a free stone of a coarser texture than poft, and not so hard; is so lax as to be easily pervious to water; when broke, is apparently of a coarse sandy substance; is friable and moulders to sand when exposed to the wind and rain; has frequently white shining spangles in it, and pebbles or other small stones inclosed in its mass. Of this, there are two kinds commonly met with, distinguished by their colours, grey and brown, which are of different shades, lighter or darker, in proportion to the mixture of white in them. It is most generally found in strata of considerable thickness, without many secondary partings; and sometimes, tho' rarely, it is subdivided into layers as thin as the common grey slate. It has generally sandy or soft partings.

4. *Of Mettle-stone.*] This is a tolerable hard stratum, being in point of hardness next to sand-stone; generally solid, compact, of considerable weight, and of an argillaceous substance, containing many nodules or balls of iron ore, and yellow or white pyrites; its partings, or the surfaces of its strata, are hard polished and smooth as glass. When broke, it has a dull dully appearance, (tho' of a fine texture), like hard dried clay mixed with particles of coal. Tho' hard in the mine or quarry, when exposed to the fresh air it falls into very small pieces. The most usual colour of this stone is black; but there are several other lighter colours, down to a light brown or grey. It is easily distinguished from free-stone by its texture and colour, as well as by its other characteristics. It lies in strata of various thicknesses, tho' seldom so thick as the two last mentioned kinds of stone.

5. *Of Shiver.*] This stratum is more frequently met with in coaleries than any other. There are many varieties of it, both in hardness and colour; but they all agree in one general characteristic. The black colour is most common; it is called by the miners *black shiver*, *black mettle*, or *bleas*. It is softer than mettle-stone, and in the mine is rather a tough than a hard substance, is not of a solid or compact matter, being easily separable, by the multitude of its partings, &c. into very small parts, and readily absorbing water. The substance of this stratum, is an indurated bole, commonly divided into thin lamina of unequal thicknesses, which break into long small pieces when struck with force; and, on examination, they appear to be small irregular rhomboids: each of these small pieces has a polished glassy surface; and, when broke across the grain, appears of a dry leafy, or laminated texture, like exceeding fine clay: it is very friable; feels to the touch like an unctuous substance; and dissolves in air or water to a fine pinguid black clay. There are almost constantly found inclosed in its strata, lumps or nodules of iron ore; often real beds of the same.

There are other colours of this stratum besides black. The brown or dun shiver is very frequently

Coalery.

met with, it agrees with the above description in every thing but colour. Grey shiver is also very common: it seems to be only a mixture of the black and dun; and by the different degrees of mixture of these colours others are produced. It lies in strata sometimes of considerable thickness, at other times not exceeding a few feet; they are commonly parted from each other by lamina of spar, coal, or soft matter.

6. *Of Coal.*] Referring the reader, for the scientific division of coals, to the articles *AMPELITES* and *LITHANTHRAX*, we shall here consider them as distinguishable into three kinds, according to their degrees of inflammability.

1. The least inflammable kinds, are those known by the name of *Welsh coal*, which is found in Wales; *Kilkenny coal*, which is found near Kilkenny in Ireland; and *blind or deaf coal*, which is found in many parts of Scotland and England. This coal takes a considerable degree of heat to kindle it, but when once thoroughly ignited will burn a long time; it remains in the fire in separate pieces without sticking together or caking; it produceth neither flame nor smoke, and makes no cinder, but burns to a white stony flagg; it makes a hot glowing fire like charcoal or cinders; and emits effluvia of a suffocating nature which renders it unfit for burning in dwelling-houses, its chief use being amongst maltsters, dyers, &c. for drying their commodities. 2. *Open burning coal*, soon kindles, making a hot pleasant fire, but is soon consumed: it produceth both smoke and flame in abundance; but lies open in the fire, and does not cake together so as to form cinders, its surface being burnt to ashes before it is thoroughly calcined in the midst; from this it has its name of an *open burning coal*; it burns to white or brown ashes very light. Of this kind is *canal-coal*, *jett*, *parrot*, *splint*, and most of the coals in Scotland. 3. *Close burning coal*, kindles very quickly, makes a very hot fire, melts and runs together like bitumen, the very smallest culm making the finest cinders, which being thoroughly burnt are porous and light as a pumice stone, and when broke are of a shining lead colour; it makes a more durable fire than any other coal, and finally burns to brown or reddish coloured heavy ashes. Of this kind are the *Newcastle* and several other of the English coals, and the *smithy coals* of Scotland. The open burning and the close burning coal mixed together, make a more profitable fire for domestic uses than either of them separate.

In all those districts of country where coal is found, there are generally several strata of it; perhaps all the different kinds above mentioned will be found in some, and only one of the kinds in others; yet this one kind may be divided into many different seams or strata, by beds of shiver or other kinds of matter interposing, so as to give it the appearance of so many separate strata.

All these strata above described, with their several varieties, do not lie or bear upon each other in the order in which they are described, nor in any certain or invariable order. Though there be found the same kinds of strata in one coalery or district as in another, yet they may be of very different thicknesses. In some places there are most of the hard kinds, in others

most of the softer; and in any one district it rarely happens that all the various kinds are found; for some kinds, perhaps, occur only once or twice, whilst others occur 10 or 20 times before we reach the principal stratum of coal.

In order to explain this, suppose the strata in the pit at A (fig. 3.) lie in the order *a, b, c, d, &c.* they may be so much altered in their thicknesses, by reason of some of them increasing and others diminishing, at the distance of B, that they may be found there of very different thicknesses; or if they are examined in a pit at D, by reason of its lower situation, and the strata there not being a continuation of those in the other places, they may be very different both in their order and thicknesses, and yet of the same kinds.

Though they be thus found very different in one coalery or district from what they are found to be in another, with respect to their thicknesses, and the order in which they lie upon each other, yet we never meet with a stratum of any kind of matter but what belongs to some of those above described.

To illustrate how the various strata lie in some places, and how often the same stratum may occur betwixt the surface and the coal, we shall give the following example. The numbers in the left hand column refer to the classes of strata before described, to which each belongs. The second column contains the names of the strata; and the four numeral columns to the right hand, express the thickness of each stratum, in fathoms, yards, feet, and inches.

EXAMPLE.				
N ^o		Fa	Yds	Fe
	Soil and gravel	0	1	10
	Clay mixed with loose stones	1	1	0
3	Coarse brown sand-stone, with soft partings	3	0	2
2	White post, with shivery partings	1	10	5
5	Black shiver or bleas, with iron-stone balls	2	0	2
6	Coarse splint coal	0	0	2
5	Soft grey shiver	0	1	0
2	Brown and grey post, streaked with black	1	0	2
5	Black shiver, with beds and balls of iron-stone	0	1	2
4	Grey and black mottle-stone	0	1	1
2	White and brown post	1	1	0
5	Black and grey shiver, streaked with white	0	1	0
3	Soft grey sand-stone, with shivery partings	0	1	1
2	Yellow and white post, with sandy partings	1	0	2
5	Black and dun shiver, with iron-stone balls	0	1	2
2	White post streaked with black, and black partings	1	0	0
5	Grey shiver, with iron-stone balls	0	1	0
4	Brown and black mottle-stone	1	1	2
5	Hard slatey black shiver	1	1	0
6	Coal, hard and fine splint	0	0	3
5	Soft black shiver	0	0	3
6	Coal, fine and clear	0	0	3
5	Hard black shiver	0	0	1
Total Fathoms,		25	0	0

In this instance the species of sand-stone only occurs twice, post five times, whilst the shiver occurs no less than nine times.

To apply the foregoing observations to practice.

Suppose it was required to examine whether there was coal in a piece of ground adjoining to, or in the neighbourhood, of other coaleries.

In the first place, it is proper to be informed, at some of the adjacent coaleries, of the number and kinds of

Coalery.

Plate
LXXXI.

10
The order
in which
they lie.

11
Methods of
searching
for coal.

Coalery. of strata; the order in which they lie upon each other; to what point of the horizon, and in what quantity, they dip; if any dikes, hitches, or troubles, and the course they stretch. Having learnt these circumstances, search in the ground under examination where the strata are exposed to view, and compare these with the other. If they be of the same kinds, and nearly correspond in order and thickness, and be lying in a regular manner, and agree by computation with the dip and rise, it may safely be concluded the coal is there; and the depth of it may be judged from the depth of the coal in the other coalery, below any particular stratum which is visible in this.

Rule 2d. If the solid strata are not exposed to view, neither in the hills nor valleys of the ground under examination, then search in the adjoining grounds; and if the same kind of strata are found there as in the adjacent coalery, and there is reason, from the dip and other circumstances, to believe that they stretch through the ground to be examined; it may then be concluded that the coal is there, as well as these other strata.

Plate LXXXI. Suppose a coalery is on the side of a hill at A, fig. 2. and you would search for a coal at B, on the other side of the hill, but in a much lower situation; by observing the several strata lying above the coal at A, and the point to which they dip, which is directly towards B, (if clear of dikes,) you may expect to find the same kind of strata on the other side of the hill, but much lower down. Accordingly, if some of the strata are visible in the face of the precipice C, they may be compared with some of those in the pit at A. Or, if they are not to be seen there, by searching in the opposite hill, they may perhaps be discovered at the place F; where, if they be found in the manner before mentioned, and there be reason to believe they extend regularly from the first place to this, it is more than probable the coal, as well as these strata, will be found in the intermediate ground.

Rule 3d. If the ground to be examined lie more to the rise of the coal, as at E, which being supposed to be on a flat, perhaps the solid strata there may be wholly covered by the gravel, clay, &c. of the outward surface lying upon them: In this case, by measuring the horizontal distance and the descent of ground from A to E, and computing the quantity of ascent or rise of the coal in that distance; by comparing these together, it may be judged at what depth the coal will be found there, allowing that it lie regular. Thus, suppose the coal at A 80 yards deep, the distance from A to E 500 yards, and that the coal rises 1 yard in 10 yards of horizontal distance:

Then, from the depth of the pit - 80
Deduct the descent of ground from A to E,
suppose - - - 24

This remainder would be the depth, if the coal was level - 56

But as the coal rises 1 in 10 feet, then deduct what it rises in 500 yards, which is 50

And the remainder is the depth of that coal at E - - - 6 Yards.

Rule 4th. Or suppose that the place at B is 500 yards the contrary way, or to the full dip of the coal at A; if a

view of the solid strata cannot be obtained, then by proceeding in the same manner as before, the depth of the coal at that place may be computed. Thus,

To the depth of the coal at the pit A - 80
Add the descent or inclination of the coal in 500 yards, which, as before, is - 50

This sum would be the depth, if the ground was level - 130

But as the ground descends towards B, deduct the quantity of that, which suppose 80

Remains the depth of the coal at B 50

If the place to be examined be neither to the full dip nor full rise, but in some proportion towards either, the same method may be pursued, computing how much the coal rises or dips in a certain distance in that direction.

If there is known to be a dike in the workings of the pit at A, which elevates or depresseth the strata towards the place under examination, then the quantity of the elevation or depression must be accordingly added to or deducted from the computed depth of the coal at that place. Suppose there is an upcast dike of 10 fathoms or 20 yards towards B, then deduct 20 from 50, the depth before computed, there will remain 30 yards or 15 fathoms for the depth of the coal at B.

But it often happens that coal is to be searched for, in a part of the country, at such a considerable distance from all other coaleries, that by reason of the intervention of hills, valleys, unknown dikes, &c. the connection or relation of the strata with those of any other coalery cannot be traced by the methods last mentioned; in which case a more extensive view must be taken of all circumstances than was necessary in the former; and a few general rules founded on the foregoing observations, and on conclusions drawn from them, will greatly assist in determining, sometimes with a great degree of probability, and sometimes with absolute certainty, whether coal be in any particular district of country or not.

The first proper step to be taken in such a case, is to take a general view of that district of country intended to be searched, in order to judge, from the outward appearance or face of the country; which particular part out of the whole is the most likely to contain those kind of strata favourable to the production of coal; and consequently such particular part being found, is the most advisable to be begun with in the examination.

Though the appearance of the outward surface gives no certain or infallible rule to judge of the kinds of strata lying beneath, yet it gives a probable one: for it is generally found, that a chain of mountains or hills rising to a great height, and very steep on the sides, are commonly composed of strata much harder and of different kinds from those before described wherein coal is found to lie, and therefore unfavourable to the production of coal; and these mountainous situations are also more subject to dikes and troubles, than the lower grounds, so that if the solid strata composing them gave even favourable symptoms of coal,

Coalery.		Coalery.
Hills and Valleys.	<p>yet the last circumstance would render the quality bad, and the quantity precarious ; and, on the whole, it may be observed, that mountainous situations are found more favourable to the production of metals than of coal. It is likewise generally found that those districts abounding with valleys, moderately rising hills, and interspersed with plains sometimes of considerable extent, do more commonly contain coal, and those kinds of strata favourable to its production, than either the mountainous or champaign countries ; and a country so situated as this last described, especially if at some considerable distance from the mountains, ought to be the first part appointed for particular examination. Plains, or level grounds of great extent, generally situated by the sides of rivers, or betwixt such moderate rising grounds as last described, are also very favourable to the production of coal, if the solid strata, and other circumstances in the higher grounds adjoining, be conformable ; for it will scarcely be found, in such a situation, that the strata are favourable in the rising grounds on both sides of the plain, and not so in the space betwixt them. Though plains be so favourable, in such circumstances, to the production of coal, yet it is often more difficult to be discovered in such a situation, than in that before described ; because, the clay, soil, and other lax matter, brought off the higher grounds by rains and other accidents, have generally covered the surface of such plains to a considerable depth, which prevents the exploration of the solid strata there, unless they be exposed to view by digging, quarrying, or some such operation.</p> <p>That part of the district being fixed upon which abounds with moderate hills and valleys as properest to begin the examination at, the first step to be taken is to examine all places where the solid strata are exposed to view, (which are called the <i>crops</i> of the strata), as in precipices, hollows, &c. tracing them as accurately and gradually as the circumstances will allow, from the uppermost stratum or highest part of the ground to the very undermost : and if they appear to be of the kinds before described, it will be proper to note in a memorandum book their different thicknesses ; the order in which they lie upon each other ; the point of the horizon to which they dip or incline, and the quantity of that inclination ; and whether they lie in a regular state. This should be done in every part of the ground where they can be seen : observing at the same time, that if a stratum can be found in one place, which has a connection with some other in a second place, and if this other has a connection with another in a third place, &c. ; then, from these separate connections, the joint correspondence of the whole may be traced, and the strata, which in some places are covered, may be known by their correspondence with those which are exposed to view.</p> <p>If by this means the crops of all the strata cannot be seen, (which is often the case), and if no coal be discovered by its crop appearing at the surface ; yet if the strata that have been viewed consist of those kinds before described, and are found lying in a regular order, it is sufficiently probable that coal may be in that part of the district, although it be concealed from sight by the surface of earth or other matter.</p>	Rule 6th.
	<p>Therefore, at the same time that the crops of the strata are under examination, it will be proper to take notice of all such springs of water as seem to be of a mineral nature, particularly those known by the name of iron water, which bear a mud or sediment of the colour of rusty iron, having a strong astringent taste. Springs of this kind proceed originally from those strata which contain beds or balls of iron-ore ; but by reason of the tenacity of the matter of those strata, the water only disengages itself slowly from them, descending into some more porous or open stratum below, where, gathering in a body, it runs out to the surface in small streams or rills. The stratum of coal is the most general reservoir of this water ; for the iron-stone being lodged in different kinds of shiver, and the coal commonly connected with some of them, it therefore descends into the coal, where it finds a ready passage through the open backs and cutters. Sometimes, indeed, it finds some other stratum than coal to collect and transmit it to the surface ; but the difference is easily distinguishable ; for the ochrey matter in the water, when it comes from a stratum of coal, is of a darker rusty colour than when it proceeds from any other, and often brings with it particles and small pieces of coal ; therefore, wherever these two circumstances concur in a number of these kind of springs, situated in a direction from each other answerable to the stretch or to the inclination of the strata, it may be certain the water comes off coal, and that the coal lies in a somewhat higher situation than the apertures of the springs.</p> <p>There are other springs also which come off coal, and are not distinguishable from common water, otherwise than by their astringency, and their having a blue scum of an oily or glutinous nature swimming upon the surface of the water. These, in common with the others, bring out particles of coal, more especially in rainy seasons when the springs flow with rapidity. When a number of these kinds are situated from each other in the direction of the strata, as above described ; or if the water does not run forth as in springs, but only forms a swamp, or an extension of stagnant water beneath the turf ; in either case, it may be depended upon that this water proceeds from a stratum of coal.</p> <p>If the stratum of coal is not exposed to view, or cannot be discovered by the first method of searching for the crop, although the appearance of the other strata be very favourable, and afford a strong probability of coal being there ; and if the last-mentioned method of judging of the particular place where the crop of the coal may lie, by the springs of water issuing from it, should, from the deficiency of those springs or other circumstances, be thought equivocal, and not give a satisfactory indication of the coal ; then a further search may be made in all places where the outward surface, or the stratum of clay or earth, is turned up by plowing, ditching, or digging, particularly in the lower grounds, in hollows, and by the sides of streams. These places should be strictly examined, to see if any pieces of coal be intermixed with the substance of the superior lax strata ; if any such be found, and if they be pretty numerous and in detached pieces, of a firm substance, the angles perfect or not</p>	Rule 7th.

Fig. 1.

Fig. 8.

Fig. 6.

Fig. 3.

Fig. 7.

Fig. 4.

Coalery.

much worn, and the texture of the coal distinguishable, it may be concluded, that the stratum of coal to which they originally did belong, is at no great distance, but in a situation higher with respect to the horizon; and if there be also found along with the pieces of coal, other mineral matter, such as pieces of flint or freestone, this is a concurrent proof, that it has come only from a small distance. Though the two fore-mentioned methods should only have produced a strong probability, yet if this last mentioned place, where the pieces of coal, &c. are found in the clay, be in a situation lower than the springs; when this circumstance is joined to the other two, it amounts to little less than a moral certainty of the stratum of coal being a very little above the level of the springs. But if, on the contrary, these pieces of coal are found more sparingly interperfed in the superior stratum, and if the angles are much fretted or worn off, and very little of other kinds of mineral matter connected with them; it may then be concluded, that they have come from a stratum of coal situated at a greater distance than in the former case; and by a strict search and an accurate comparison of other circumstances, that particular place may be discovered with as much certainty as the other.

After the place is thus discovered, where the stratum of coal is expected to lie concealed, the next proper step to be taken, is to begin digging a pit or hole there perpendicularly down to find the coal. If the coal has no solid strata above and beneath it, but be found only embodied in the clay or other lax matter, it will not be there of its full thickness, nor so hard and pure as in its perfect state when enclosed betwixt two solid strata, the uppermost called the *roof*, and the undermost called the *pavement*, of the coal: in such situation therefore it becomes necessary, either to dig a new pit, or to work a mine forward until the stratum of coal be found included betwixt a solid roof and pavement, after which it need not be expected to increase much in its thickness: yet as it goes deeper or farther to the dip, it most likely will improve in its quality; for that part of the stratum of coal which lies near the surface, or only at a small depth, is often debased by a mixture of earth and sundry other impurities, washed down from the surface, through the backs and cutters by the rains; whilst the other part of the stratum which lies at a greater depth is preserved pure, by the other solid strata above it, intercepting all the mud washed from the surface.

The above methods of investigation admit of many different cases, according to the greater or less number of favourable circumstances attending each of the modes of inquiry; and the result accordingly admits every degree of probability, from the most distant even up to absolute certainty. In some situations, the coal will be discovered by one method alone; in others, by a comparison of certain circumstances attending each method; whilst in some others, all the circumstances that can be collected only lead to a certain degree of probability.

In the last case, where the evidence is only probable, it will be more advisable to proceed in the search by boring a hole through the solid strata (in the manner hereafter described), than by digging or sinking a

pit, it being both cheaper and more expeditious; and in every case, which does not amount to an absolute certainty, this operation is necessary, to ascertain the real existence of the coal in that place.

We shall now suppose, that having examined a certain district, situate within a few miles of the sea or some navigable river, that all the circumstances which offer only amount to a probability of the coal being there, and that boring is necessary to ascertain it, we shall therefore describe the operation of boring to the coal; then the method of clearing it from water, commonly called *winning* it; and all the subsequent operations of working the coal and raising it to the surface, leading it to the river or harbour, and finally putting it on board the ships.

Suppose that the ground, A, B, C, D, fig. 4. has been examined, and from the appearance of the strata for where they are visible (as at the precipice D, and several other places) they are found to be of those kinds usually connected with coal, and that the point to which they rise is directly west towards A, but the ground being flat and covered to a considerable depth with earth, &c. the strata cannot be viewed in the low grounds; therefore, in this and all similar situations, the first hole that is bored for a trial for coal should be on the west side of the ground, or to the full rise of the strata as at A, where, boring down through the strata 1, 2, 3, suppose 10 fathoms, and not finding coal, it will be better to bore a new hole than to proceed to a great depth in that: therefore, proceeding so far to the eastward as B, where the stratum 1, of the first hole is computed to be 10 or 12 fathoms deep, a second hole may be bored, where boring down through the strata 4, 5, 6, 7, 8, the stratum 1 is met with, but no coal; it would be of no use to bore farther in this hole, as the same strata would be found which were in the hole A: therefore, proceeding again so far to the eastward, as it may be computed the stratum 4 of the second hole will be met with at the depth of 10 or 12 fathoms, a new hole may be bored at C; where, boring through the strata 9, 10, 11, 12, the coal is met with at 13, before the hole proceed so deep as the stratum 4 of the former. It is evident, that, by this method of procedure, neither the coal nor any other of the strata can be passed over, as the last hole is always bored down to that stratum which was nearest the surface in the former hole.

The purposes for which boring is used, are numerous, and some of them of the utmost importance in coaleries. In coaleries of great extent, although the coal be known to extend through the whole grounds, yet accidental turns, and other alterations in the dip, to which the coal is liable, render the boring of three or more holes necessary, to determine exactly to what point of the horizon it dips or inclines, before any capital operation for the winning of it can be undertaken; because a very small error in this may occasion the loss of a great part of the coal, or at least incur a double expence in recovering it.

Suppose A, B, C, D, fig. 5. to be part of an extensive field of coal, intended to be won or laid dry by a fire-engine; according to the course of the dip in adjoining coaleries, the point C is the place at which the engine should be erected, because the coal dips in direction.

Coalery.

direction of the line A C, consequently the level line would be in the direction C D; but this ought not to be trusted to. Admit two holes, 1 2, be bored to the coal in the direction of the supposed dip, at 200 yards distance from each other, and a third hole 3 at 200 yards distance from each of them: suppose the coal is found, at the hole 1, to be 20 fathoms deep; at the hole 2, 10 fathoms deeper; but at the hole 3, only 8 fathoms deeper than at 1. Then to find the true level line and dip of the coal, lay, As 10 fathoms the dip from 1 to 2, is to 200 yards the distance, so is 8 fathoms, the dip from 1 to 3, to 160 yards, the distance from 1 on the line 1 2, to *a*, the point upon a level with the hole 3. Again lay, As 8 fathoms, the dip from 1 to 3, is to 200 yards the distance; so is 10 fathoms, the dip from 1 to 2, to 250 yards, the distance from 1, in direction of the line 1, 3, to *b*, the point upon a level with the hole 2. Then let fall the perpendicular 1, *c*, which will be the true direction of the dip of the coal, instead of the supposed line A C; and by drawing E D, and D F, parallel to the other lines, the angle D, and no other place, is the deepest part of the coal, and the place where the engine should be erected. If it had been erected at the angle C, the level line would have gone in the direction *c b*, by which means about one third part of the field of coal would have been below the level of the engine, and perhaps lost, without another engine was erected at D.

Boring not only shews the depth at which the coal lies, but its exact thickness; its hardness; its quality, whether close burning or open burning, and whether any foul mixture in it or not; also the thickness, hardness, and other circumstances of all the strata bored through; and from the quantity of water met with in the boring, some judgment may be formed of the size of an engine capable of drawing it, where an engine is necessary. When holes are to be bored for these purposes, they may be fixed (as near as can be guessed) in such a situation from each other, as to suit the places where pits are afterwards to be sunk; by which means most of the expence may be saved, as these pits would otherwise require to be bored, when sinking, to discharge their water into the mine below. There are many other uses to which boring is applied, as will be explained hereafter.

For these reasons, boring is greatly practised in England, and is brought to great perfection; and as the operation is generally entrusted to a man of integrity, who makes it his profession, the accounts given by him of the thickness and other circumstances of the strata, are the most accurate imaginable, and are trusted to with the greatest confidence; for as very few gentlemen choose to take a lease of a new coalery which has not been sufficiently explored by boring, it is necessary the accounts should be faithful, being the only rule to guide the landlord in letting his coal, and the tenant in taking it. In Scotland it is not so generally practised; nor are there any men of character who are professed borers, that operation being commonly left to any common workman; whence it happens, that it never has been in any esteem, the accounts given by them being so imperfect and equivocal as not to merit any confidence.

Coalery.

The tools or instruments used in boring are very simple. The boring rods are made of iron from 3 to 4 feet long, and about one inch and a half square, with a screw at each end, by which they are screwed together, and other rods added as the hole increases in depth. The chisel is about 18 inches long, and two and a half broad at the end, which being screwed on at the lower end of the rods, and a piece timber put through an eye at the upper end, they are prepared for work. The operation is performed by lifting them up a little, and letting them fall again, at the same time turning them a little round; by a continuance of which motions, a round hole is fretted or worn through the hardest strata. When the chisel is blunt, it is taken out, and a scooped instrument called a *wimble* put on in its stead; by which the dust or pulverised matter which was worn off the stratum in the last operation is brought up. By this subsistence, the borers know exactly the nature of the stratum they are boring in; and by any alteration in the working of the rods, (which they are sensible of by handling them) they perceive the least variation of the strata. The principal part of the art depends upon keeping the hole clean, and observing every variation of the strata with care and attention.

The established price of boring in England is 5 s. *per* fathom for the first five fathoms, 10 s. *per* fathom for the next five fathoms, and 15 s. *per* fathom for the next five fathoms; and so continually increasing 5 s. *per* fathom at the end of every five fathoms; the borer finding all kinds of boring instruments, and taking his chance of the hardness of the strata, except above one foot in thickness of whin occur, when the former price ceases, and he is paid *per* day.

It is exceedingly uncommon to meet with a stratum of coal which is naturally dry, or whose subterranean springs or feeders of water are so very small as to require no other means than the labour of men to draw off or conduct them away; for it most commonly happens, that the stratum of coal, and the other strata adjacent, abound so much in feeders of water, that, before access can be had to the coal, some other methods must be pursued to drain or conduct away these feeders: therefore, after the deepest part of the coal is discovered, the next consideration is of the best method of draining it, or, in the miner's language, of *winning* the coal.

If the coal lies in such an elevated situation, that a part of it can be drained by a level brought up from the lower grounds, then that will be the most *natural* method; but whether it be the most *proper* or not, depends upon certain circumstances. If the situation of the ground be such, that the level would be of a great length, or have to come through very hard strata, and the quantity of coal it would drain, or the profits expected to be produced by that coal, should be inadequate to the expence of carrying it up; in such case some other method of winning might be more proper. Or suppose, in another case, it be found, that a level can be had to a coalery, which will cost L. 2000, and require five years to bring it up to the coal, and that it will drain 30 acres of coal when completed; yet if it be found that a fire engine, or some other machine, can be erected on that coalery, for the same sum of money,

13
Of winning
the coal.

Galery.

money, in one year, which will drain 50 acres of the same coal, then this last would be a more proper method than the level; because four years profit would be received by this method before any could come in by the other; and after the 30 acres drained by the level is all wrought, a machine of some kind would nevertheless be necessary to drain the remaining 20 acres: so that erecting a machine at first would be on all accounts the most advisable.

Where a level can be drove, in a reasonable time, and at an adequate expence, to drain a sufficient tract of coal, it is then the most eligible method of winning; because the charge of upholding it is generally less than that of upholding fire-engines or other machines.

If a level is judged properest after consideration of every necessary circumstance, it may be begun at the place appointed in the manner of an open ditch, about three feet wide, and carried forward until it be about six or seven feet deep from the surface, taking care to secure the bottom and sides by timber-work or building; after which it may be continued in the manner of a mine about three feet wide, and three feet and a half high, through the solid strata, taking care all along to keep the bottom upon a level, and to secure the roof, sides, and bottom, by timber or building, in all places where the strata are not strong enough to support the incumbent weight, or where they are liable to decay by their exposure to the fresh air. If the mine has to go a very long way before it reach the coal, it may be necessary to sink a small pit, for the convenience of taking out the stones and rubbish produced in working the mine, as well as to supply fresh air to the workmen; and if the air should afterwards turn damp, then square wooden pipes made of staves closely jointed, (commonly called air-boxes), may be fixed in the upper part of the mine, from the pit-bottom all the way to the end of the mine, which will cause a sufficient circulation of fresh air for the workmen; perhaps in a great length it will be found proper to sink another or more pits upon the mine, and by proceeding in this manner it may be carried forward until it arrive at the coal; and after driving a mine in the coal a few yards to one side, the first coal-pit may be sunk.

If a level is found impracticable, or for particular reasons unadvisable; then a fire-engine*, or some other machine, will be necessary, which should be fixed upon the deepest part of the coal, or at least so far towards the dip as will drain a sufficient extent of coal, to continue for the time intended to work the coalery; and whether a fire-engine, or any other machine, is used, it will be of great advantage to have a partial level brought up to the engine-pit, if the situation of the ground will admit it at a small charge, in order to receive and convey away the water without drawing it so high as to the surface: for if the pit was 30 fathoms deep to the coal, and if there was a partial level, which received the water five fathoms only below the surface, the engine by this means would be enabled to draw 1-6th part more water than without it; and if there were any feeders of water in the pit above this level, they might be conveyed into it, where they would be discharged without being drawn by the engine.

Coalery.

The engine-pit may be from seven to nine feet wide; and whether it be circular, oval, or of any other form, is not very material, provided it be sufficiently strong, though a circular form is most generally approved. If any feeders of water are met with a few fathoms from the surface, it will be proper to make a circular or spiral cutting about one foot deep, and a little hollowed in the bottom, round the circumference of the pit, in order to receive and conduct the water down, without flying over the pit and incommoding the workmen. If the strata are of so tender or friable a nature as not to bear this operation, or if the water leaks through them, then it will be necessary to insert in the forementioned cutting a circular piece of timber called a *crib*, hollowed in the same manner to collect the water; and a second may be inserted two or three yards below the first, with a sloping notch down the wall or side of the pit, to convey the water from the former into it; proceeding by some of these methods until the pit is sunk 15 or 20 fathoms; at which place it would be proper to fix a cistern or reservoir, for the first or upper set of pumps to stand in; for if the pit be 30 fathoms as supposed, it would be too great a length for the pumps to be all in one set from bottom to top; therefore, if any extraordinary feeders are met with, betwixt 15 and 20 fathoms deep, it would be best to fix the cistern where it may receive them, and prevent their descending to the bottom; observing that the upper set of pumps be so much larger than the lower one, as the additional feeders may require; or if there are no additional feeders, it ought then to be a little smaller.

After the upper cistern is fixed, the operation may be pursued by the other set of pumps in much the same manner as has been described, until the pit is sunk to the coal; which being done, it would be proper to sink it six or eight feet deeper, and to work some coal out from the dip side of the pit, to make room for a large quantity of water to collect, without incommoding the coal-pits when the engine is not working.

It would exceed the proper bounds of this article, to enumerate all the accidents to which engine-pits are liable in sinking; we shall therefore only recite a few which seem important.

If a quicksand happen to lie above the solid strata, next the surface, it may be got through by digging the pit of such a wideness at the top (allowing for the natural slope or running of the sand) as to have the proper fix of the pit on the uppermost solid stratum; where fixing a wooden frame or tube as the timber-work of the pit, and covering it round on the outside with wrought clay up to the top, the sand may again be thrown into the excavation round the tube, and levelled with the surface.

If the quicksand should happen to lie at a considerable depth betwixt the clay and solid strata, then a strong tube of timber closely jointed and shod with iron, of such a diameter as the pit will admit, may be let down into it; and by fixing a great weight upon the top, and by working out the sand, it may be made to sink gradually, until it come to the rock or other solid stratum below; and when all the sand is got out, if it be lightly calked and secured it will be sufficient.

It sometimes happens, that a stratum of soft matter, lying betwixt two hard solid ones, produces so large a quantity of water as greatly to incommode the operations. In such a case, a frame-work of plank, strengthened with cribs and closely calked, will stop back the whole or the greatest part of it, provided the two strata which include it are of a close texture: or let an excavation of about two feet be made in the soft stratum, quite round the circumference of the pit; and let that be filled close up betwixt the two hard strata, with pieces of dry fir-timber about 10 inches square inserted endwise, and afterwards as many wooden wedges driven in to them as they can be made to receive; if this be well finished, little or no water will find a passage through it.

It rarely happens that any suffocating damp or foul air is met with in an engine-pit, the falling of water and the working of the pumps, generally causing a sufficient circulation of fresh air; but that kind of combustible vapour or inflammable air, which will catch fire at a candle, is often met with; it proceeds from the partings, backs, and cutters, of the solid strata, exhaling from some in an insensible manner, whilst from others it blows with as great impetuosity as a pair of bellows. When this inflammable air is permitted to accumulate, it becomes dangerous by taking fire, and burning or destroying the workmen, and sometimes by its explosion will blow the timber out of the pit, and do considerable damage. If a considerable supply of fresh air is forced down the pit by air-boxes and a ventilator, or by dividing the pit into two by a close partition of deals from top to bottom, or by any other means, it will be driven out, or so weakened, that it will be of no dangerous consequence; or when the inflammable air is very strong, it may be safely carried off by making a close sheathing or lining of thin deals quite round the circumference of the pit, from the top of the solid strata to the bottom, and lengthening it as the pit is sunk, leaving a small vacancy behind the sheathing; when the combustible matter, which exhales from the strata, being confined behind these deals, may be vented by one or two small leaden pipes, carried from the sheathing to the surface; so that very little of it can transpire into the area of the pit. If a candle be applied to the orifice of the pipe at the surface, the inflammable air will instantly take fire, and continue burning like an oil lamp until it be extinguished by some external cause. Upon the whole, every method should be used to make the pit as strong in every part, and to keep it as dry as possible; and whenever any accident happens, it should be as expeditiously and thoroughly repaired as possible, before any other operation be proceeded in, lest an additional one follow, which would more than double the difficulty of repairing it.

The first operations, after sinking the engine-pit, are the working or driving a mine in the coal, and sinking the first coal-pit. The situation of the first coal-pit should be a little to the rise of the engine-pit, that the water which collects there may not obstruct the working of the coals every time the engine stops: and it should not exceed the distance of 20, 30, or 40 yards; because when the first mine has to be driven a long way, it becomes both difficult and expensive. If

there be not a sufficient circulation of fresh air in the mine, it may be supplied by the before described air-boxes and a ventilator, until it arrive below the intended coal-pit, when the pit may be bored and sunk to the coal, in the manner before mentioned.

After the pit is thus got down to the coal, the next consideration should be of the best method of working it. The most general practice in Scotland is to excavate and take away a part only of the stratum of coal in the first working of the pit, leaving the other part as pillars for supporting the roof; and after the coal is wrought in this manner to such a distance from the pit as intended, then these pillars, or so many of them as can be got, are taken out by a second working, and the roof and other solid strata above permitted to fall down and fill up the excavation. The quantity of coal wrought away, and the size of the pillars left in the first working, is proportioned to the hardness and strength of the coal and other strata adjacent, compared with the incumbent weight of the superior strata.

The same mode of working is pursued in most parts of England, differing only as the circumstances of the coalery may require: for the English coal, particularly in the northern counties, being of a fine tender texture, and of the close-burning kind, and also the roof and pavement of the coal in general not so strong as in Scotland, they are obliged to leave a larger proportion of coal in the pillars for supporting the roof, during the first time of working; and, in the second working, as many of these pillars are wrought away as can be got with safety.

The Scots coal in general being very hard, and of the open-burning kind, it is necessary to work it in such a manner as to produce as many great coals as possible, which is best effected by taking away as high a proportion of the coal as circumstances will allow in the first working; on the contrary, the English coal being very tender cannot possibly be wrought large, nor is it of much importance how small they are, being of so rich a quality; so that a larger proportion may be left in pillars in this coal than could with propriety be done in the other; and, when all circumstances are considered, each method seems well adapted to the different purposes intended.

The ancient method of working was, to work away as much of the coal as could be got with safety at one working only; by which means the pillars were left so small as to be crushed by the weight of the superior strata, and entirely lost. As great quantities of coals were lost by this method, it is now generally exploded, and the former adopted in its place; by which a much larger quantity of coal is obtained from the same extent of ground, and at a much less expence in the end.

The exact proportion of coal proper to be wrought away, and to be left in pillars at the first working, may be judged of by a comparison of the circumstances before mentioned. If the roof and pavement are both strong, as well as the coal and the pit about 30 fathoms deep, then two-thirds, or probably three-fourths, may be taken away at the first working, and one-third or one-fourth left in pillars. If both roof and pavement be soft or tender, then a larger proportion

portion must be left in pillars, probably one-third or near one-half; and in all cases the hardness or strength of the coal must be considered. If tender, it will require a larger pillar than hard coal; because, by being exposed to the air after the first working, a part of it will moulder and fall off, by which it will lose much of its solidity and resistance.

The proportion to be wrought away and left in pillars being determined, the next proper step is to fix upon such dimensions of the pillars to be left, and of the excavations from which the coal is to be taken away, as may produce that proportion. In order to form a just idea of which, see a plan of part of a pit's workings (fig. 6.) supposed to be at the depth of 30 fathoms, and the coal having a moderate rise. *A*, represents the engine-pit; *B*, the coal-pit; *A a B*, the mine from the former to the latter; *B C*, the first working or excavation made from the coal-pit, commonly called the *winning mine* or *winning headway*, nine feet wide; *b b b b*, &c. the workings called *rooms*, turned off at right angles from the others, of the width of 12 feet; *c c c c*, &c. the workings called *thirlings* or *thirlings*, 9 feet wide, wrought through at right angles from one room to another; *d d d*, &c. the pillars of coal left at the first working for supporting the roof, 18 feet long and 12 feet broad; *D D*, two large pillars of coal near the pit bottom, 15 or 20 yards long, and 10 or 15 broad, to support the pit and prevent its being damaged by the roof falling in; *e e*, the level mine wrought in the coal from the engine-pit bottom, 4 or 5 feet wide; *f f*, &c. large pillars of coal left next the level, to secure it from any damage by the roof falling in; *g g*, a dike which depresseth the coal, 1 fathom; *h h*, &c. large pillars and barriers of coal left unwrought, adjoining to the dike where the roof is tender, to prevent its falling down. The coal taken out by the first working in this pit is supposed to be one-third of the whole: and allowing the rooms 12 feet wide, and the thirlings 9 feet wide, then the pillars will require to be 12 feet wide and 18 feet long; for if one pillar be in a certain proportion to its adjoining room and thirling, the whole number of pillars will be in the same proportion to the whole number of rooms and thirlings in the pit. Suppose *A B C D*, (fig. 7.) to be a pillar of coal 18 feet long and 12 feet broad, its area will be 216 square feet; *A C H E*, the adjoining thirling, 12 feet by 9 feet, and its area 108 square feet; *B A E F G*, the adjoining room, 27 feet long and 12 feet broad, and its area 324 square feet; which added to 108 gives 432 square feet, or two-thirds wrought, and 216 square feet left, or one-third of the whole area *F G H D*.

It is proper to observe, that in the prosecution of the workings, the rooms to the right of the winning headway should be opposite to the pillars on the left; and the first, third and fifth pillar, or the second, fourth and sixth, adjoining to the said headway, should be of such a length as to overlay the adjoining thirlings; as, in the plan, the pillar 2 overlays the thirlings 1 and 3; and the pillar 4, overlays the thirlings 3 and 5; this will effectually support the roof of the main road *B C*, and will bring the other pillars into their regular order, by which means each pillar will be opposite to two thirlings. Also a larger pro-

portion of coal than common should be left in all places which are intended to be kept open after the second working; such as the pit-bottoms, air-courses, roads, and water-courses, or where the roof is tender, as it generally is near dikes, hitches, and troubles; and if the roof should continue tender for a considerable space, it will perhaps be found proper to leave a few inches of coal adhering to the roof, which, together with a few props of timber fixed under it, may support it effectually for a long time. The level mine *e e*, and the winning headway *B C*, should be wrought forward a considerable length before the other rooms, in order to be drove through any dikes that might interpose; otherwise the progress of the workings might probably be stopped a considerable time, waiting until a course of new rooms were procured on the other side of the dike. Suppose the dike *g g*, fig. 6, to depress the coal six feet or one fathom, and that it rises in the same manner on the under side of the dike as it does on the upper side; in such a case the only remedy would be to work or drive a level mine through the strata of stone from the engine-level at *e*, over the dike, until it intersect the coal at *i*; and from thence to drive a new level mine in the coal at *i i*, and a new winning headway *i k*. In order to gain a new set of rooms, and to supply fresh air to this new operation, a small mine might be drove from the room *b*, and a hole sunk down upon the level room *i i*; therefore, if the level mine *e e* was not drove so far forward as to have all these operations completed before the rooms and other workings were intercepted by the dike, the working of the pit might cease until these new places were ready.

If there be two or three strata or seams of coal in the same pit (as there often are) having only a stratum of a few feet thick lying betwixt them, it is then material to observe, that every pillar in the second seam be placed immediately below one in the first, and every pillar in the third seam below one in the second; and in such a situation the upper stratum of coal ought to be first wrought, or else all the three together: for it would be unsafe to work the lower one first, lest the roof should break, and damage those lying above.

It sometimes becomes necessary to work the coal lying to the dip of the engine or the level, which coal is consequently drowned with water, and must therefore be drained by some means before it can be wrought. If the quantity of water proceeding from it be inconsiderable, it may then be drained by small pumps laid upon the pavement of the coal, and wrought by men or horses, to raise the water up to the level of the engine-pit bottom: or if the feeders of water be more considerable, and the situation be suitable, the working road of these pumps might be connected with those in the engine-pit; by which means the water would be raised up to the level: but if the quantity of water be very great; or if, from other circumstances, these methods may not be applicable; then the engine-pit may be sunk as deep below the coal as may be necessary, and a level stone mine drove from its bottom to the dip of the strata, until it intersect the stratum of coal, from whence a new level mine might be worked, which would effectually drain it. Sup-

Coalery.

pose A B, fig. 8. to be a section of the engine-pit; B C, the coal drained by the engine; B D, the coal to the dip of the engine intended to be drained; then if the engine-pit be sunk deeper to E, a stone mine may be wrought in the direction E D, until it intersect the coal at D, by which the water will have a free passage to the engine, and the coal will be drained.

If there be another stratum of coal lying at such a depth below the first as the engine-pit is intended to be sunk to, the upper seam may in some situations be conveniently drained, by driving a mine in the lower seam of coal from E to F, and another in the upper one from B to D; and by boring a hole from D to F, the water will descend to F, and, filling the mine E F, rise up to the engine-pit bottom at E, which is upon a level with D.

Whenever it is judged necessary to work the pillars, regard must be had to the nature of the roof. If the roof is tender, a narrow room may be wrought through the pillar from one end to the other, leaving only a shell of coal on each side for supporting the roof the time of working. Suppose A B C D, fig. 7. to be a pillar of coal 18 feet long, and 12 feet broad; if the roof is not strong, the room 1, 2, 3, 4, of eight feet wide may be wrought up through that pillar, leaving a shell of two feet thick on each side; and if it can be safely done, a part of these shells may also be wrought away, by working two places through them as at 5 and 6. By this means very little of the coal will be lost; for two-thirds of the whole being obtained by the first working, and above two-thirds of the pillar by the second working, the loss upon the whole would not exceed one-tenth; but it may be observed, that some pillars will not produce so great a proportion, and perhaps others cannot be wrought at all; so that upon the whole there may be about one-eighth, one-seventh, or in some situations one-sixth part of the coal lost. If the roof be hard and strong, then as much coal may be wrought off each side and each end of the pillar as can be done with safety, leaving only a small piece standing in the middle; and when the roof is very strong, sometimes several pillars may be taken entirely out, without any loss of coal: and in general this last method is attended with less loss, and produces larger coals, than the former. In all cases it is proper to begin working those pillars first, which lie farthest from the pit bottom, and to proceed working them regularly away towards the pit; but if there be a great number of pillars to the dip of the pit, it is the safest method to work these out before those to the rise of the pit are begun with.

There is no great difference in the weight of different kinds of coals, the lightest being about 74 pounds avoirdupois, and the heaviest about 79 pounds the cubic foot; but the most usual weight is 75 pounds the foot, which is 18 hundred weight, and 9 pound the cubic yard. The statute chaldron is 53 hundred weight; or when measured is as follows, 268.8 cubic inches to the Winchester gallon; 4½ gallons to the coal peck, about 3 pounds weight; 8 coal pecks to the boll, about 247½ pounds; and 24 bolls to the chaldron, of 53 hundred weight. If one coal measuring exactly a cubic yard (nearly equal to 5 bolls) be broke into pieces of a moderate size, it will measure seven coal-bolls and a half.

If broke very small, it will measure 9 bolls; which shews that the proportion of the weight to the measure, depends upon the size of the coals: therefore accounting by weight, is the most rational method.

Coalery.

A TABLE of the weight and quantity of coal contained in one acre Scots measure, allowing one sixth part to be lost below ground, in seams of the following thicknesses.

Thickness of coal.	Weight in tons.	Quantity in chaldrons.
Feet. Inches.		
2 0	3068	1158
2 6	3835	1447
3 0	4602	1736
3 6	5369	2025
4 0	6136	2314
4 6	6903	2603
5 0	7670	2892
5 6	8437	3181
6 0	9204	3470

We shall next mention some of the various methods of bringing the coals from the rooms and other workings to the pit bottom. Where the stratum of coal is of a sufficient thickness, and has a moderate rise and dip, the coals are most advantageously brought out by horses, who draw out the coals in a tub or basket placed upon a sledge: a horse by this means will bring out from four to eight hundred weight of coals at once, according to the quantity of the ascent or descent. In some coaleries they have access to the workings by a mine made for them, sloping down from the surface of the earth to the coal; and where that convenience is wanting, they are bound into a net, and lowered down the pit. If the coal be not of such a height as to admit horses, and has a moderate rise like the last, then men are employed to bring out the coals: they usually draw a basket of four or five hundred weight of coals, fixed upon a small four-wheeled carriage. There are some situations in which neither horses nor men can be properly used; particularly where the coal has a great degree of descent, or where many dikes occur: in such a case the coals are best brought out by women called *bearers*, who carry them in a kind of basket upon their backs, usually a hundred or a hundred weight and a half at once.

When the coals are brought to the pit bottom, the baskets are then hooked on to a chain, and drawn up the pit by a rope to the surface, which is best effected by a machine called a *gin*, wrought by horses. There are other kinds of gins for drawing coals, some wrought by water, others by the vibrating lever of a fire-engine; but either of these last is only convenient in some particular situations, those wrought by horses being in most general use. After the coals are got to the surface, they are drawn a small distance from the pit, and laid in separate heaps: the largest coals in one heap, the smaller pieces called *chews* in another, and the *cullm* or *pan-coal* in a separate place.

There is an accident of a very dangerous nature to which all coaleries are liable, and which has been the ruin of several: it is called a *crush*, or a *sift*. When the pillars of coal are left so small as to fall, or yield under the weight of the superior strata; or when the

15

and sifts.

payment

Coalery.

Coalery.

pavement of the coal is so soft as to permit the pillars to sink into it, which sometimes happens by the great weight that lies upon them; in either case the solid stratum above the coal breaks and falls in, crushes the pillars to pieces, and clofeth up a great extent of the workings, or probably the whole coalery. As such an accident seldom comes on suddenly, if it be perceived in the beginning, it may sometimes be flopped by building large pillars of stone amongst the coal pillars: but if it has already made some progress, then the best method is to work away as many of the coal pillars adjoining to the crush as may be sufficient to let the roof fall freely down; and if it makes a breach of the solid strata from the coal up to the surface, it will very probably prevent the crush from proceeding any farther in that part of the coalery. If the crush begins in the rise part of the coalery, it is more difficult to stop it from proceeding to the dip, than it is to stop it from going to the rise when it begins in a contrary part.

Foul air.

Another circumstance proper to be taken notice of is the foul or adulterated air so often troublesome in coaleries. Of this there are two kinds: the black damp or styth, which is of a suffocating nature; and the inflammable or combustible damp. Without staying to inquire, in this place, into the origin and effects of these damp, it may be sufficient to observe, that, in whatever part of any coalery a constant supply or a circulation of fresh air is wanting, there some of these damp exist, accumulate in a body, and become noxious or fatal: and wherever there is a good circulation of fresh air, they cannot accumulate, being mixed with and carried away by the stream of air as fast as they generate or exhale from the strata. Upon these principles are founded the several methods of ventilating a coalery. Suppose the workings of the pits A and B (fig. 6.) to be obnoxious to the inflammable damp; if the communication was open betwixt the two pits, the air which went down the pit A, would proceed immediately along the mine *a*, and ascend out of the pit B; for it naturally takes the nearest direction: so that the air in all the workings would be stagnant; and they would be utterly inaccessible from the accumulation of the combustible damp. In order to expel this, the air must be made to circulate through all the different rooms, by means of collateral air-courses made in this manner: The passage or mine *a* must be closed up or stopped by a partition of deals, or by a wall built with bricks or stones, to prevent the air passing that way. This building is called a *stopping*. There must also be stoppings made in the thirlings 1 1 1, &c. betwixt the pillars *ff*, &c. which will direct the air up the mine *e*, until it arrive at the innermost thirling 2, which is to be left open for its passage. There must also be stoppings made at the side of the mine *a* at *mm*, and on both sides of the main headway BC at *bb*, &c. then returning to the innermost thirling 2, proceed to the third row of pillars, and build up the thirlings 2 2, &c. leaving open the thirling 3 for a passage for the air; and proceeding on to the fifth row of pillars, build up in the same manner the stoppings 3 3, &c. leaving open 4 for an air course: and by proceeding in this manner to stop up the thirlings or passages in every other row of pillars, the current of fresh air will circulate through and ventilate

the whole workings, in the direction pointed to by the small arrows in the plan, clearing away all the damp and noxious vapours that may generate. When it is arrived at C, it is conducted across the main headway, and carried through the other part of the pit's workings in the same manner, until it return through *nn* to the pit B, where it ascends; and as the rooms advance farther, other stoppings are regularly made.

In some of those stoppings, on the sides of the main headway, there must be doors to admit a passage for the bringing out of the coals from the rooms to the pit, as at 5 5; these doors must be constantly shut, except at the time of passing through them.

There are other methods of disposing the stoppings so as to ventilate the pit; but none which will so effectually disperse the damp as that described above. If the damp are not very abundant, then the course of stoppings 1 1 1, &c. in the level mine, and the others at *bb*, &c. in the main-headway, without any others, may perhaps be sufficient to keep the pit clear. If at any time the circulation of the fresh air is not brisk enough, then a large lamp of fire may be placed at the bottom of the pit B, which, by rarefying the air there, will make a quicker circulation.

Most of the larger coaleries send their coals to the ships for the coaling trade or exportation; and, as the quantity is generally very large, it would take a greater number of carts than could conveniently be obtained at all times to carry them; besides the considerable expence of that manner of carriage: they therefore generally use waggons, for carrying them along waggon-ways, laid with timber, by which means one horse will draw from two to three tons at a time, when in a cart not above half a ton could be drawn.

The first thing to be done in making a waggon-way is to level the ground in such a manner as to take off all sudden ascents and descents: to effect which, it is sometimes necessary to cut through hills, and to raise an embankment to carry the road through hollows. The road should be formed about 12 feet wide; and no part should have a greater descent than of one yard perpendicular in 10 of a horizontal line, nor a greater ascent than one yard in 30. After the road is formed, pieces of timber, about six feet long, and six inches diameter, called *sleepers*, are laid across it, being 18 or 24 inches distant from each other. Upon these sleepers other pieces of timber, called *rails*, of four or five inches square, are laid in a lateral direction, four feet distant from each other, for the waggon-wheels to run upon; which being firmly pinned to the sleepers, the road may then be filled with gravel, and finished.

The waggons have four wheels, either made of solid wood or of cast iron. The body of the carriage is longer and wider at the top than at the bottom; and usually has a kind of trap-door at the bottom, which, being loosed, permits the coals to run out without any trouble. The size of a waggon to carry 50 hundred weight of coals is as follows:

	Feet.	Inches.
Length of the top	7	9
Breadth of the top	5	0
Length of the bottom	5	0
Breadth of the bottom	2	6
Perpendicular height	4	3

the coal.

Plate
LXXXI.

Where the pits are situated at some considerable distance from the harbour, it becomes necessary to have a store-house near the shipping place, where the coals may be lodged, until the lighters or ships are ready to take them in. The waggon-way should be made into the store-house, at such a height from the ground, as to permit the coals to run from the waggons down a spout into the vessels; or else to fall down into the store-house, as occasion may require.

This kind of store-house is well adapted to dispatch and saving expence: for a waggon-load of coals may be delivered either into the store-house or vessels instantly with very little trouble: and if the coals were exposed to the effects of the sun and rain, they would be greatly injured in their quality; but being lodged under cover of the store-house, they are preserved.

COALITION, the reunion of the parts of a body before separated.

COALLIER, a vessel employed to carry coals from one port to another; chiefly from the northern parts of England to the capital, and more southerly parts, as well as to foreign markets. This trade is known to be an excellent nursery for seamen; although they are often found, from the constitution of their climate, not to be so well calculated for southern navigation.

COAST, a sea-shore, or the country adjoining to the edge of the sea. Dr Campbell, in his political survey of Great Britain, considers an extensive sea-coast as of great advantage to any kingdom; and consequently that this island hath many conveniences resulting from the extent of its coasts, superior to other kingdoms which are much larger. The chief advantages arising from an extensive sea-coast are, that thus there is a convenient opportunity for exportation and importation to or from all parts of the kingdom. Thus, a number of cities are formed on the coasts; by this means the internal parts are improved, &c. The extent of the sea-coasts of Arabia, he looks upon as the genuine source of wealth and splendour to the ancient inhabitants of that peninsula; the same was the instrument of the greatness of ancient Egypt, of Phenicia, &c. In short, according to him, no country or city can for any length of time be flourishing, unless it hath a considerable connection with the sea. "It is indeed true, (says he) that the wisdom and industry of man, taking hold of some peculiar circumstances, may have rendered a few inland cities and countries very fair and flourishing. In ancient history we read of Palmyra, and the district round it, becoming a luxuriant paradise in the midst of inhospitable deserts. But this was no more than temporary grandeur; and it has now lain for some ages in ruins. The city and principality of Kandahar was in like manner rendered rich and famous, in consequence of its being made the centre of the Indian commerce; but, long ago declining, its destruction has been completed, in our days, from that dreadful desolation which Thamas Kouli Khan spread through Persia and the Indies. Here, in Europe, many of the large cities in Germany, which for a time made a great figure from the freedom and industry of the inhabitants, and diffused ease, plenty, and prosperity, through the districts dependent on them, which of course rendered them populous, are now so much sunk,

through inevitable accidents, as to be but shadows of what they were; and, though they still continue to subsist, subsist only as the melancholy monuments of their own misfortunes. We may therefore, from hence, with great certainty, discern, that all the pains and labour that can be bestowed in supplying the defect of situation in this respect, proves, upon the whole, but a tedious, difficult, and precarious expedient. But, however, we must at the same time admit, that it is not barely the possession even of an extended coast that can produce all these desirable effects. That coast must likewise be distinguished by other natural advantages; such as capes and promontories, favourably disposed to break the fury of the winds; deep bays, safe roads, and convenient harbours. For, without these, an extended coast is no more than a maritime barrier against the naval force of other nations; as is the case in many parts of Europe; and is one of the principal reasons why Africa derives so little benefit from a situation which has so promising an appearance; there being many considerable tracts upon its coasts, equally void of havens and inhabitants, and which afford not the smallest encouragement to the attempting any thing that might alter their present desolate condition. It is, however, a less inconvenience, and in some cases no inconvenience at all, if, in the compass of a very extended coast, there should be some parts difficult or dangerous of access, provided they are not altogether inaccessible.—The sea-coast of Britain, from the figure, in some measure, of the island, but chiefly from the inlets of the sea, and the very irregular indented line which forms its shore, comprehends, allowing for those sinuities, at least 800 marine leagues: we may, from hence, therefore, with safety affirm, that in this respect it is superior to France, though that be a much larger country; and equal to Spain and Portugal in this circumstance, though Britain is not half the size of that noble peninsula, which is also singularly happy in this very particular."

COASTING, in navigation, the act of making a progress along the sea-coast of any country. The principal articles relating to this part of navigation are, the observing the time and direction of the tide; knowledge of the reigning winds; of the roads and havens; of the different depths of the water, and qualities of the ground.

COASTING-Pilot a pilot, who by long experience has become sufficiently acquainted with the nature of any particular coast, and of the requisites mentioned in the preceding article, to conduct a ship or fleet from one part of it to another.

COAT, or COAT of ARMS, in heraldry, a habit worn by the ancient knights over their arms both in war and tournaments, and still borne by heralds at arms. It was a kind of surcoat, reaching as low as the navel, open at the sides with short sleeves, sometimes furled with ermine and hair, upon which were applied the armories of the knights embroidered in gold and silver, and enamelled with beaten tin-coloured black, green, red, and blue; whence the rule never to apply colour on colour, nor metal on metal. The coats of arms were frequently open, and diversified with bands and fillets of several colours, alternately placed, as we still see cloths scarleted, watered, &c. Hence they were

Coat
| Cobalt.

were called *devils*, as being divided and composed of several pieces sewed together; whence the words *faulx*, *pale*, *chevron*, *bend*, *croisi*, *salzier*, *lozenge*, &c. which have since become honourable pieces, or ordinaries of the shield. See *CROSS*, *BEND*, *CHEVRON*, &c.

Coats of arms and banners were never allowed to be worn by any but knights and ancient nobles.

COAT, in anatomy. See *TUNIC*.

COAT of Mail, a kind of armour made in form of a shirt; consisting of iron rings wove together netwise. See *MAIL*.

COATI, in zoology, a synonyme of a species of *VIPERA*, and *URSUS*.

COATIMUNDI, a variety of the above.

COATING, among Chemists. See *CHEMISTRY*, n° 81.

COATING of Vials, panes of Glass, &c. among electricians, is usually performed by covering the outside of the vial with tinfoil, brags or gold-leaf, &c. and filling its inside with loose pieces of brags-leaf, by which means it becomes capable of being charged. See *ELECTRICITY*.

COBALT, a genus of fossils of the order of the asphurclata. In its purer state it is considerably compact and heavy, and not unfrequently of a semi-metallic appearance. Its texture is always fine; sometimes granulated, or composed of minute grains ranged into small strise; sometimes smooth and even, without any distinguishable grain. Its colour is sometimes a pale iron grey; sometimes a darker bluish or blackish grey. From variations of this kind, some mineralogists have divided it into distinct species, the principal of which are these. 1. Dark-grey cobalt; compact, ponderous, and of a very fine grain. This sort is said to be the most esteemed in Saxony, and to produce the finest blue glass. 2. Bright pale-grey, or ash-coloured cobalt, of a somewhat looser structure, and less ponderous. This kind has a great resemblance to the arsenical pyrite, and some of the white silver and copper ores, from which those who are accustomed to the inspection of these minerals distinguish it pretty readily, by the colour of the cobalt being somewhat duller, and its texture finer. 3. Vitreous cobalt; in structure resembling melted scoria or glass, of a bright bluish-grey colour, called, by the Germans, *schlacken-kobolt*, slag cobalt. 4. Crystalliform cobalt, affecting chiefly a cubical figure sometimes perfect, but commonly with the angles imperfect. 5. Specular cobalt, intermixed with glittering talky flakes. 6. Earthy cobalt, blended with various earths into soft friable compounds, of a black, yellowish-grey, or other colours. 7. Flowers of cobalt. These are of a loose radiated structure, and generally not so heavy as the foregoing ores. The external parts are of a fine purplish red, a violet, or a peach-bloom colour. Sometimes the whole mass is elegantly tinged with these colours throughout; but more commonly the internal parts are of a greyish or leaden hue. They are never found in great quantities, or forming regular veins; but only in detached masses, lodged in clefts of stones; in places to which the air has had free access. They appear to proceed from a spontaneous resolution of some of the foregoing minerals; most of which

Cobalt.
| Cobbling.

are found to yield nearly similar effervescences on being exposed in heaps for a length of time to a moist air. Wherever the workmen meet with these flowers, they expect a rich vein of cobalt in the neighbourhood.

Cobalt is found most plentifully in Saxony, particularly near Schneeberg in the district of Misnia. The mines here are said to be two or three hundred fathoms deep; and the cobalt lodged at great depths to be of a better quality than such as is near the surface. The Schneeberg hill, according to the ancient chronicles of Saxony, yielded at first only an iron ore; which, on sinking deeper, about the beginning of the 14th century, was succeeded by a very rich ore of silver. This also being at length exhausted gave place to cobalt. Some pieces of the cobalt ores are still found to participate of silver, and even of gold: but these metals, far from being essential, as some have supposed, to all cobalts, are entirely accidental even in this. Cobalt has also been found in some parts of England, particularly in Mendip-hills in Somersetshire, and in Cornwall. Its quality, however, is found to be somewhat different from that found in Saxony. This country has long supplied all the world with zaffre and smalt, the most valuable productions from cobalt; great quantities of them being thence exported even to the East Indies. It is supposed that the Chinese, and more particularly the Japanese, had formerly mines of an excellent cobalt, from the produce of which were painted the fine blues of their ancient porcelains; but that these mines are now exhausted, and that the inferior blues of their present ware are painted with the Saxon zaffre imported to them by the Dutch.

Cobalt contains a great quantity of arsenic, and it is from this mineral that most of the arsenic we have is prepared. The greatest quantities are made at Geyerberg in Misnia, from cobalt and other arsenical ores brought from Schneeberg. The ore is thrown into a furnace resembling a baking oven; whose flue is an horizontal pipe near 100 fathoms in length, considerably wide at the end which communicates with the furnace, and growing gradually narrower to the other end. The ore is every now and then stirred and turned in the furnace to promote the extrication of the arsenic, which arises in fumes into the pipe, and there condenses into a greyish or blackish powder called *meal arsenic*. This is refined by a second sublimation in close vessels, with the addition of a little potash which detains its impurities. In this operation, the fire which elevates the arsenic, heating the receiver, the flowers melt together into the crystalline masses brought to us. From cobalt, also, are prepared the substances called *zaffre* and *smalt*, used for tinging glass of a blue colour. See *ZAFFRE* and *SMALT*.

Regulus of COBALT, a kind of semi-metal prepared from cobalt, of a whitish colour inclining to red. For the manner of its preparation, see *ZAFFRE*. For its chemical properties, see *CHEMISTRY*, n° 159, 212, 213, 259.

COBBING, a punishment sometimes inflicted at sea. It is performed by striking the offender a certain number of times on the breech with a flat piece of wood

Cobitis
Coccinella.

wood called the *robbing-board*. It is chiefly used as a punishment to those who quit their station during the period of the night-watch.

COBITIS, the *LOACHE*, in ichthyology, a genus of fishes belonging to the order of abdominales. The eyes are in the upper part of the head. The branchiostegic membrane has from four to five rays; and the body is nearly of an equal thickness throughout. The species are five; three of which are natives of Europe. The loache is found in several of our small rivers, keeping at the bottom on the gravel; and is, on that account, in some places called the *groundling*: It is frequent in the stream near Amesbury in Wiltshire, where the sportsmen, thro' frolic, swallow it down alive in a glass of white-wine.

COBLENTZ, an ancient, handsome, and strong town of Germany, in the electorate of Trier or Treves, seated at the confluence of the rivers Rhine and Moselle, in a fertile country, with mountains covered with vineyards. It is the usual residence of the elector of Treves, to whom it belongs. E. Long. 7. 18. N. Lat. 50. 24.

COBOB, the name of a dish among the Moors. It is made of several pieces of mutton wrapt up in the cawl, and afterwards roasted in it; the poorer people, instead of the meat, use the heart, liver, and other parts of the entrails, and make a good dish, though not equal to the former.

COBURG, a town of Germany in the circle of Franconia, and capital of a territory of the same name, with a famous college, a fort, and a castle. This town, with its principality, belongs to the house of Saxony, and the inhabitants are Protestants. It is seated on the river Itz, in E. Long. 11. 5. N. Lat. 50. 20.

COBWEB, in physiology, the fine net-work which spiders spin out of their own bowels, in order to catch their prey. See *ARANEÆ*.

COCCÆIUS (John), professor of theology at Bremen, was founder of a sect called *Cocceians*: they held, amongst other singular opinions, that of a visible reign of Christ in this world, after a general conversion of the Jews and all other people to the true Christian faith, as laid down in the voluminous works of Cocceius. He died in 1699, aged 66.

COCCIFEROUS PLANTS, the same with *bacciferous*. See *BACCIFEROUS*.

COCCINELLA, in zoology, a genus of insects, of the coleoptera order. The antennæ are fulclavated, and truncated; the polypi are shaped like a heart; the body is of a hemispherical figure; the breast and elytra are marginated; and the belly is plain. The species are forty-nine, mostly distinguishable by the number and colour of the spots on their wings, and the plants upon which they live. The *coccinella cacti*, a native of the warmer parts of America, is the famous cochineal animal, so highly valued in every part of the world for the incomparable beauty of its red colour, which it readily communicates to wool and silk, but with much more difficulty to linen and cotton. This insect, like all others, is of two sexes, but exceedingly dissimilar in their appearance. The female, which alone is valuable for its colour, is ill-shaped, tardy, and stupid: its eyes, mouth, and antennæ, are fixed so deep, and are so concealed in

the folds of the skin, that it is impossible to distinguish them without a microscope. The male is very scarce, and is sufficient for 300 females or more; it is active, small, and slender in comparison with the female; its neck is narrower than the head, and still narrower than the rest of the body. Its thorax is of an elliptic form, a little longer than the neck and head put together, and flattened below; its antennæ are jointed, and out of each joint issue long, slender hairs that are disposed in pairs on each side. It has six feet, each formed of distinct parts. From the posterior extremity of its body two large hairs or bristles are extended, that are four or five times the length of the insect. It bears two wings that are fixed to the upper part of the thorax, which falls like the wings of common flies when it walks or rests. These wings, which are of an oblong form, are suddenly diminished in breadth where they are connected to the body. They are strengthened by two oblong muscles; one of which extends itself on the outside all round the wing; and the other, which is internal and parallel to the former, seems interrupted towards the summit of the wings. The male is of a bright red; the female of a deeper colour. They are bred on a plant known in Oaxaca in New Spain, and all those parts where it abounds, by the name of *nopal*, or *no-palleca*, the *Indian fig-tree**, which, except in the difference of the foliage, resembles the tinos, so common in the kingdom of Andalusia; the leaf of the tuna being broad, flat and prickly, and that of the nopal, oblong, with several eminences; and instead of spines has a fine smooth membrane, of a permanent and lively green.

The method of planting the nopal, is by making rows of holes about half a yard deep, and about two yards distant from one another. In each of these holes is placed one or two leaves of the nopal, in a flat position, and then covered with earth. This leaf soon after shoots up into a single stem, which during its growth divides into several branches, and these successively produce fresh leaves, the largest being nearest to the stem, which is full of knots, as are also the branches, and from these the leaves have their origin. The usual height of this plant is about three yards, which it seldom exceeds. The season when the nopal displays all its beauty and vigour, is like that of other plants, from the spring to the autumn, which at Oaxaca and other parts of North America is at the same time as in Spain. Its blossom is small, of a bright red, and in the shape of a bud; from the centre of which proceeds the tuna, a name given to its fruit; and as this increases the blossom fades, till at length it falls. When the tuna, or fig, is ripe, the outward skin becomes white; but the pulp is so fully impregnated with a deep red, that it tinges the urine of those who eat it of a blood colour, a circumstance attended with no small uneasiness to those who are unacquainted with this particular. Few fruits, however, are either more wholesome or pleasant.

The ground where the nopal is intended to be planted, must be carefully cleaned from all kinds of weeds, as they drain the soil of those juices which the nopal requires. Also after the cochineal is taken from the plant, which is never done till the insects are arrived

Coccinella.

* A species of *Opuntia*.

at perfection, all the superfluous leaves are plucked off, that they may be succeeded by others the following year. For it must be observed, that the cochineal which are bred on young plants thrive much better, and are of a finer quality, than those produced on such as have stood some years.

The cochineal was formerly imagined to be a fruit or seed of some particular plant; an error which probably arose from an ignorance of the manner in which it is propagated; but at present every one is convinced of its being an insect, agreeably to its name, signifying a wood-louse, which generally breeds in damp places, especially in gardens. These insects, by rolling themselves up, form a little ball something less than a pea; and in some places are known by the name of *baguillas de San Anton*, i. e. St Anthony's little cows: and such is the figure of the cochineal, except that it has not the faculty of rolling itself up; and its magnitude, when at its full growth, does not exceed that of a tick, common in dogs and other animals.

These insects breed and are nourished on the nopals, where their eggs are placed among the leaves; the juice of the plant, which is their sole nourishment, becomes converted into their substance; when, instead of being thin and watery, and, to all outward appearance, of little or no use, is rendered a most beautiful crimson colour. The plant is in May or June in its most vigorous state, and at this most favourable season the eggs are deposited; and in the short space of two months, from an animalcule, the insect grows up to the size above mentioned: but its infant state is exposed to a variety of dangers; the violent blasts of the north wind sweep away the eggs from the foliage of the plant; and, what is equally fatal to their tender constitutions, showers, fogs, and frosts, often attack them, and destroy the leaves, leaving the careful cultivator this only resource, namely, that of making fires at certain distances, and filling the air with smoke, which frequently preserves them from the fatal effects of the inclemency of the weather.

The breeding of cochineal is also greatly obstructed by birds of different kinds, which are very fond of these insects; and the same danger is to be apprehended from the worms, &c. which are found among the plantations of nopals: so that unless constant care be taken to fright the birds away from the plantation, and to clear the ground of those various kinds of vermin, which multiply so fast in it, the owner will be greatly disappointed in his expectations.

When the insects are at their full growth, they are gathered and put into pots of earthen ware; but much attention is requisite to prevent them from getting out, as, in that case, great numbers of them would be lost; though there is no danger of it, where they are at liberty on the nopal leaves, those being their natural habitation, and where they enjoy a plenty of delicious food: for, though they often remove from one leaf to another, they never quit the plant; nor is it uncommon to see the leaves entirely covered with them, especially when they are arrived at maturity. When they have been confined some time in these pots, they are killed and put in bags. The Indians have three different methods of killing these insects,

one by hot water, another by fire, and a third by the rays of the sun: and to these are owing the several gradations of the colour, which in some is dark, and in others bright; but all require a certain degree of heat. Those therefore who use hot water are very careful to give it the requisite heat, and that the quantity of water be proportioned to the number of insects. The method of killing the creatures by fire is to put them on shovels into an oven moderately heated for that intention; the fine quality of the cochineal depending on its not being over dried at the time of killing the insects: and it must be owned, that among the several ways made use of to destroy this valuable creature, that of the rays of the sun seems to bid fairest for performing it in the most perfect manner.

Besides the precaution requisite in killing the cochineal, in order to preserve its quality, it is equally necessary to know when it is in a proper state for being removed from the leaves of the nopal; but as experience only can teach the cultivator this necessary criterion, no fixed rule can be laid down. Accordingly, in those provinces where the cultivation of these insects is chiefly carried on, those gathered by Indians of one village differ from those gathered in another; and even those gathered by one person in the same village, are often different from those gathered by another; every individual adhering to his own method.

The cochineal-insect may, in some circumstances, be compared to the silk-worm, particularly in the manner of depositing its eggs. The insects destined for this purpose are taken at a proper time of their growth, and put into a box well closed, and lined with a coarse cloth that none of them be lost: and in this confinement they lay their eggs and die. The box is kept close shut till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a sufficient indication that the animalcule has life, though the egg is so minute as hardly to be perceived; and this is the seed placed on the foliage of the nopal, and the quantity contained in the shell of a hen's egg is sufficient for covering a whole plant. It is remarkable that this insect does not, or at least in any visible manner, injure the plant, but extracts its nourishment from the most succulent juice, which it sucks by means of its proboscis through the fine teguments of the leaves.

The principal countries where the cochineal insects are bred, are Oaxaca, Plasfala, Chulula, Nueva Galicia, and Chiapa, in the kingdom of New Spain; and Hambato, Loja, and Tucuman in Peru: but it is only in Oaxaca, that they are gathered in large quantities, and form a branch of commerce, the cultivation of these little creatures being there the chief employment of the Indians.

Though the cochineal belongs to the animal kingdom, of all others the most liable to corruption, yet it never spoils. Without any other care than merely that of keeping in a box, it has been preserved for ages. In drying, it loses about two-thirds of its weight. When dried, it is sorted into large entire grains, and small or broken ones: the first are called by the Spaniards *grana*, the latter *graniilla*. In trade, four sorts are distinguished, *Meslique*, *Campechane*, *Tetraschale*, and

Cocco-
thraustes
||
Coccus.

and *syzygster*; of which, the first is accounted the best, and the last the worst. The three first are named from the places where they are produced; the latter from its being found wild without any culture. In medicine, cochineal has been strongly recommended as a sudorific, cardiac, and alexipharmac; but practitioners have never observed any considerable effects from it. Its principal consumption is among dyers. See the article DYEING.

COCOTHRUAUTES, in ornithology, the trivial name of a species of LOXIA.

COCULUS INDICUS, the name of a poisonous berry, too frequently mixed with malt-liquors, in order to make them intoxicating; but this practice is expressly forbid by act of parliament. It is the fruit of the *menispermum cocculus*. Fishermen have a way of mixing it with paste: this the fish swallow greedily, and are thereby rendered lifeless for a time, and float on the water. The good women use it with stavesacre, for destroying vermin in childrens heads.

COCCUS, in zoology, a genus belonging to the order of hemiptera. The rostrum proceeds from the breast; the belly is bristly behind; the wings of the male are erect; and the female has no wings. The species are 22, denominated principally from the plants they frequent.

Coccus Maldivia, the Maldivia nut, in the materia medica; the name of the fruit of the *palma Maldivensis* of Johnston; an oval-shaped fruit of a sweet taste, and famous for its virtues in nervous disorders.

Coccus Polonicus, an insect which may properly enough be called the *cochineal* of the northern part of the world. As the cochineal loves only the hot climates, this creature affects only the cold ones. It is collected for the use of dyers: but the crops of it are much smaller, more difficultly made, and the drug itself greatly inferior to the true cochineal. It is commonly known by the name of *coccus Polonicus*, or the *scarlet grain of Poland*. That country is indeed the place where it is gathered in the greatest abundance; but it is not the only one where it is found. It is to be met with in many of the northern countries; and possibly may be found in some of the more temperate ones, where it is not yet known; as it is very much hid by nature from the eyes of common observers. It is found affixed to the root of a plant, and usually to plants of that species, from thence called *polygonum cocciferum*: though authors have informed us of the *fame berry*, as it is often called, being found at the roots of the mouse-ear, rupture-wort, pimpinell, and pellitory of the wall; and that it is in no other than sandy places that it is found at the roots of those plants. Breynius in 1731, printed at Dantzick a very curious account of this production, which proves it uncontestedly to be an animal. Towards the end of June the coccus is in a fit state for being gathered. Every one of the creatures is then nearly of a spherical form, and of a fine violet colour. Some of them, however, are not larger than poppy seeds, and others of the size of a pepper-corn; and each of them is lodged, either in part or entirely, in a sort of cup like that of an acorn. More than half the surface of the body of the animal is covered by this cup. The outside of the covering is rough, and of a blackish brown; but the inside is

smooth, polished, and shining. On some plants they find only one or two of these, and on others more than forty; and they are sometimes placed near the origin of the stalks of the plants.

Breynius began his observations on the animals in this state, several of them being put into vessels of glass; and by the 24th of July, there was produced from every one of them a hexapod, or six-legged worm, with two antennæ on its head. Several of these were kept a fortnight, and shewed no inclination to eat any thing. They run about, however, very swiftly for some time; but then began to be more quiet, drew up their bodies shorter, and ceased to run about any longer. They were now in a purple colour; but in this state, though they did not walk about, they were subject to various contortions. At length, when they were become wholly motionless, their bodies became covered with a fine down; this was white, and formed them a perfect covering, which was sometimes of a spherical, and sometimes of an irregular figure: it was always, however, very elegant; and the downy matter plainly enough transpired out of the animal's body. The creatures remained in this state of rest, and covered with this down, for five or six days; but at the end of that time every one of them laid more than 150 eggs. These eggs were deposited upon the paper on which the animals were placed, and were enveloped in some measure by a downy matter. When the creatures had laid all their eggs they died; and about the 24th of August there came from every egg a small insect, which to the eye scarce seemed any other than a red point; it might, however, be observed very plainly to move about. These young animals lived about a month, wholly without sustenance. Mr Breynius was induced at first to believe, that these animals came to be in a state to produce perfect eggs, without any congress with the male; but farther observations convinced him of the error of this opinion. He saw afterwards a sort of very small flies with two white wings bordered with red, produced from several of the cocci. These flies are plainly of the same kind with the male gall-insects.

It has before been observed, that these cocci differ in size. The flies are produced by the small ones not bigger than a poppy seed; the others give the worms before described: and one observation of Mr Breynius's gives a plain proof that these flies are the male insects of the species; since all those of the females, which had been a day or two accompanied by those flies, quickly covered themselves with down and began to lay their eggs; whereas those which had not this commerce with the flies remained in the same state, or else got only a very thin and slight covering of down, and never laid any eggs. The manner of this creature's life, however, from its being hatched, to its being found in the shape of a berry at the roots of the plants, is yet unknown: and how they assume the shape of a ball lodged in a cup, must require a nice observation to discover.

COCCYGÆUS MUSCULUS. See ANATOMY, *Table of the musciles*.

COCCYX, or COCCYGIS OS. See ANATOMY, n°34.
COCHIN, a town of Asia, in the kingdom of the same name, on the Malabar coast. The Dutch have here

Coccus
||
Cochin.

here a small fort named Cranganore, which lies about three miles up the river. Formerly it bore the name of a kingdom; and was once a republic of Jews, who at that time could reckon 80,000 families, but are now reduced to 4000. They have a synagogue at Cochin near the king's palace, in which are preserved their records, engraven on copper-plates in the Hebrew characters; and when any of the characters decay, they have them fresh cut. They declare themselves to be of the tribe of Manasséh, a part whereof was by Nebuchadnezzar carried to the most eastern province of his dominions, which, according to them, extended as far as Cape Comorin: and this journey 20,000 of them performed in three years after their setting out from Babylon. When they arrived in Malabar, they were received with great civility by the inhabitants, who allowed them liberty of conscience, and the use of their own customs. There, having increased in number and riches, they at length purchased the little kingdom of Kranganor, and chose two sons of an eminent family to govern the common-wealth, and reign jointly over them. But one of the brothers having killed the other, the son revenged his father's death by that of the murderer; upon which the state fell again into democracy, and still continues. The lands have long reverted into the hands of the Malabars, and many of the Jews through poverty have embraced the Hindoo religion.

COCHIN-CHINA, a kingdom of Asia, bounded on the north by Tonquin; on the east, by the sea of China; on the south, by the Indian ocean; and on the west, by Cambodia, and a ridge of mountains inhabited by a savage people called *Kemois*, who live independent of any government. Little of the history of this kingdom is known; what follows depends entirely on the credit of M. le Poivre, a French traveller.—About half a century before the French first arrived in these distant regions, a prince of Tonquin, as he fled from his sovereign, by whom he was pursued as a rebel, had, with his soldiers and adherents crossed the river, which serves as a barrier between Tonquin and Cochin-China. The fugitives who were warlike and civilized men, soon expelled the scattered inhabitants, who wandered about without any society or form of government, and founded a new kingdom, which soon grew rich and populous. During the reigns of the first six kings, no nation could be happier than the Cochin-Chinefe. Their monarchs governed them as a father does his family, establishing no laws but those of nature, to which they themselves were the first to pay obedience. They honoured and encouraged agriculture, as the most useful employment of mankind; and required from their subjects only a small annual free-gift to defray the expence of their defensive war against the Tonquinefe, who were their enemies. This imposition was regulated by way of poll-tax, with the greatest equity. Every man, able to till the ground, paid into the prince a small sum proportioned to the strength of his constitution, and the vigour of his arm: and nothing more.

Cochin-China continued happy under these princes for more than a century; but the discovery of gold-mines put a stop to these mild regulations. Luxury

immediately took place. The prince began to despise the simple habitation of his ancestors, and caused a superb palace to be built, a league in circumference, surrounded with a wall of brick in the model of that of Pekin, and defended by 1600 pieces of cannon. Not content with this, he would needs have a winter palace, an autumn palace, and a summer palace. The old taxes were by no means sufficient to defray these expences; new ones were devised; and oppression and tyranny every where took place. His courtiers, to flatter their prince, gave him the title of the *king of Heaven*, which he still continues to assume. When speaking of his subjects, he styles them his *children*, but by no means behaves as if he was their father: for our author informs us, that he has seen whole villages newly abandoned by their inhabitants, who were harassed with toil and insupportable exactions; the necessary consequence of which was, that their lands returned to their former uncultivated state.

M. le Poivre represents the Cochin-Chinefe as gentle, hospitable, frugal, and industrious. There is not a beggar in the country; and robbery and murder are absolutely unknown. A stranger may wander over the kingdom from one end to the other, (the capital excepted), without meeting with the slightest insult. He will be every where received with the most eager curiosity, but at the same time with the greatest benevolence. A Cochin-Chinefe traveller, who has not money sufficient to defray his expences at an inn, enters the first house of the town or village he arrives at, and waiting the hour of dinner, takes part with the family, and goes away when he thinks proper, without speaking a word, or any person's putting to him a single question.

The country of Cochin-China is much of the same temperature with that of Tonquin; though rather milder, as lying nearer the sea. Like Tonquin, it is annually overflowed, and consequently fruitful in rice, which requires no other manure than the mud left by the inundations. They have sugar-canes, and the same kinds of fruits common to other parts of India. The country produces no grapes, and therefore they drink a liquor brewed from rice. They have vast woods of mulberry-trees, which run up as fast as our hemp. Their silk is stronger than that of China, but not so fine. They have the best timber in the world, particularly a sort which abounds in the mountains, and is called the *incorruptible tree*; because it never rots under earth or water, and is so solid that it serves for anchors. There are two kinds, black and red. The trees are very tall, straight, and so big that two men can scarce fathom them. They have also on the mountains of the *Kemois* a tree of the most fragrant scent, which is supposed to be the same with *lignum aloes*. This, being reckoned the best product of the country, is engrossed by the king, and is sold from five to 16 ducats per pound. It is highly valued both in China and Japan, where the logs of it are sold for 200 ducats a pound, to make pillows for the king and nobility; and among those Indians which continue to burn their dead, great quantities of it are used in the funeral piles. The young trees called *agulla*, or eagle-wood, are every one's property, which makes the old

Cochin-
China
||
Cochlearia.

ones called *calamba* so scarce and dear. They have oak, and large pines, for the building of ships; so that this country is of the same use to China, that Norway is to Britain. In general, they have the same kind of trees and plants that are to be met with in Tonquin. They have mines of gold, as well as diamonds; but the last they do not value so highly as pearl. They also esteem their coral and amber very much. In all the provinces there are great granaries filled with rice, in some of which that grain is kept upwards of 30 years. One of the greatest rarities in these parts, especially in grand entertainments, is a ragout made of the eatable birds nests, which some say are found only in Cochin-China, and others in four islands that lie south of its coast. See BIRDS-NESTS.

The merchants of Cambodia, Tonquin, China, Macao, Manila, Japan and Malacca, trade to Cochin-China with plate, which they exchange for the commodities of the country. The Portuguese are the most favoured here of any Europeans. The Cochin-Chinese themselves, not being inclined to travel, seldom sail out of sight of their own shore, but purchase many trifles from foreigners at great rates, particularly combs, needles, bracelets, glass pendants, &c. They are very fond of our hats, caps, girdles, shirts, and other clothes; and, above all, set a great value on coral. The country is said to have 700 miles of coast, with many large inlets of the sea, and above 60 convenient landing places; which, however, according to Captain Hamilton, are but seldom visited by strangers.

COCHINEAL. See COCCINELLA.

COCHLEA, the shell-snail, in zoology. See HELIX.

COCHLEA, in Anatomy. See ANATOMY, n° 405.

COCHLEARIA, SCURVY-GRASS; a genus of the siliculosa order, belonging to the tetradynamia class of plants. There are six species, the most remarkable of which are, 1. The anglica, or garden scurvy-grass, grows naturally on the sea-shore, in the north of England and in Holland; but is cultivated for use in the gardens near London. It hath a fibrous root, from which arise many round succulent leaves, which are hollowed like a spoon; the stalks rise from six inches to a foot high: these are brittle, and garnished with leaves which are oblong and sinuated. The flowers are produced in clusters at the end of the branches, consisting of four small white petals which are placed in the form of a cross; and are succeeded by short, roundish, swelling, seed-vessels, having two cells divided by a thin partition. In each of these are lodged four or five roundish seeds. 2. The armoracia, or horse-radish, is so well known as to need no description.

The first is propagated by seeds, which are to be sown in July, in a moist spot of ground; and when the plants are come up they should be thinned, so as to be left at about six inches distance each way. The plants that are taken out may be transplanted into other borders. In the spring these plants will be fit for use; those that are left, will run up to seed in May, and perfect their seeds in June. If the seeds are sown in the spring they seldom grow well. The horse-radish is propagated by cuttings or buds from the sides of the old roots. The best season for this

work is in October or February; the former for dry lands, the latter for moist.

Uses. Scurvy-grass is a pungent stimulating medicine; capable of dissolving viscid juices, opening obstructions of the viscera and the more distant glands, and promoting the more fluid secretions. It is particularly celebrated in scurvy, and is the principal herb employed in these disorders in the northern countries. See MATERIA MEDICA, n° 263. Horse-radish root has a quick pungent smell, and a penetrating acrid taste; it nevertheless contains in certain vessels a sweet juice, which some times exudes on the surface. By drying it loses all its acrimony, becoming first sweetish, and then almost insipid: if kept in a cool place in sand, it retains its qualities for a considerable time. The medical effects of it are to stimulate the solids, attenuate the juices, and promote the fluid secretions: it seems to extend its action through the whole habit, and to affect the minutest glands. It has frequently done service in some kinds of scurvy and other chronic disorders proceeding from a viscosity of the juices or obstructions of the excretory ducts. Sydenham recommends it likewise in dropsies, particularly those which follow intermittent fevers. Both water and rectified spirit extract the virtues of this root by infusion, and elevate them in distillations: along with the aqueous fluid an essential oil rises, possessing the whole taste and pungency of the horse-radish.

COCHLITES, in natural history, an appellation given to the petrified shells of the cochleæ or snails.

COCK, in zoology, the English name of the males of gallinaceous birds, but more especially used for the common dunghill cock. See PHASIANUS.

Black Cock.

Cock of the Wood. } See TETRAO.

Cock-Paddle, Lump-fish, or Sea-owl. See CYCLOP-TERUS.

COCK-PIT, a sort of theatre upon which game-cocks fight.

It must appear astonishing to every reflecting mind, that a mode of diversion so cruel and inhuman as that of cock-fighting should so generally prevail, that not only the ancients, barbarians, Greeks and Romans, should have adopted it; but that a practice so savage and heathenish should be continued by Christians of all sorts, and even pursued in these better and more enlightened times.

The ancient Greeks and Romans, as is well known, were wont to call all the nations in the world Barbarians; yet certainly, if we consider the many instances of cruelty practised among them, there was very little reason for the distinction. Human sacrifices were common both to them and the barbarians; and with them the exposing of infants, the combats of men with wild beasts, and of men with men in the gladiatorial scenes, were spectacles of delight and festivity.

The islanders of Delos, it seems, were great lovers of cock-fighting; and Tanagra a city in Bœotia, the isle of Rhodes, Chalcis in Eubœa, and the country of Media, were famous for their generous and magnanimous race of chickens. The kingdom of Persia was probably included in the last, from whence this kind

Cochlearia
||
Cock.

of poultry was first brought into Greece; and if one may judge of the rest from the fowls of Rhodes and Media, the excellency of the broods at that time consisted in their weight and largeness, (as the fowls of those countries were heavy and bulky), and of the nature of what our sportsmen call shakebags or turnpokes. The Greeks, moreover, had some method of preparing the birds for battle, by feeding; as may be collected from Columella.

It should seem, that at first cock-fighting was partly a religious and partly a political institution at Athens; and was there continued for the purpose of improving the seeds of valour in the minds of their youth; but was afterwards abused and perverted both here and in the other parts of Greece to a common pastime, without any moral, political, or religious intention, and as it is now followed and practised among us.

At Rome, as the Romans were prone to imitate the Greeks, we may expect to find them following their example in this mode of diversion, and in the worst way, viz. without any good or laudable motives; since, when they took and brought it to Rome, the Greeks had forgotten every thing that was commendable in it, and had already perverted it to a low and unmeaning sport. Sigismond Hyam thinks the Romans borrowed the pastime from Dardanus in Asia; but there is little reason for making them go so far from it, when it was so generally followed in Greece, whose customs the Romans were addicted to borrow and imitate. However, it is probable, they did not adopt this opinion very early. It may be gathered from Columella, that the Romans did not use the sport in his time. This author styles cock-fighting, a *Grecian diversion*; and speaks of it in terms of ignominy, as an expensive amusement, unbecoming the frugal householder, and often attended with the ruin of the parties that followed it. The words are remarkable. "Nos enim censensus instituere vestigal industri patris familias, non rixosarum avium lanistæ, cujus plerumque totum patrimonium pignus alex, victor gallinaceus pyctes abstulit." Where he describes, as we think, the manner, not of the Romans, but of the Greeks, who had in his time converted the diversion of cock-fighting into a species of gaming, and even to the total ruin of their families, as happens but too often in England at this day. The Romans, however, at last gave into the custom, though not till the decline of the empire. The first cause of contention between the two brothers Bassianus and Geta, sons of the emperor Septimius Severus, happened, according to Herodian, in their youth, about the fighting of their cocks; and if the battling between these two princes was the first instance of it, probably they had seen and learned it in Greece, whither they had often accompanied the emperor their father.

It is observable, that cocks and quails pitted for the purpose of engaging one another, a *outrance*, or to the last gasp, for diversion, are frequently compared, and with much propriety, to gladiators. Hence Pliny's expression, *Gallorum—cum gladiatorum*; and that of Columella, *rixosarum avium lanistæ*; *lanista* being the proper term for the master of the gladiators. Consequently one would expect, that when the bloody scenes of the amphitheatre were discarded, as they

were soon after the Christian religion became the establishment of the empire, the wanton shedding of mens blood in sport, being of too cruel and savage a nature to be patronised and encouraged in an institution so harmless and innocent as the Christian was, one might justly expect that the *σπορτομαχία* and the *αλεκτρομαχία* would have ceased of course. The fathers of the church are continually inveighing against the spectacles of the *arena*, and upbraiding their adversaries with them. These indeed were more unnatural and shocking than a main of cocks; but this, however, had a tendency towards infusing the like ferocity and implacability in the breasts and dispositions of men.

Besides, this mode of diversion has been in fact the bane and destruction of thousands here, as well as those of *lanistæ avium*, *cock-feeders*, mentioned by Columella, whose patrimonial fortunes were totally dissipated and destroyed by it.

The cock is not only a useful animal, but stately in his figure, and magnificent in his plumage. "*Imperiant suo generi*, says Pliny, *et regnum, in quacunque sunt domo, exercent.*" Aristophanes compares him to the king of Persia; authors must also take notice of the "*specatissimum insigne, ferratum, quod eorum verticem regia corona modo exornat.*" His tenderness towards his brood is such, that, contrary to the custom of many other males, he will scratch and provide for them with an assiduity almost equal to that of the hen; and his generosity is so great, that, on finding a hoard of meat, he will chuckle the hens together, and, without touching one bit himself, will relinquish the whole of it to them. He was called *the bird*, κατ' εἶδος, by many of the ancients; he was highly esteemed in some countries, and in others was even held sacred, inasmuch that one cannot but regret that a creature so useful and noble, should, by a strange fatality, be so enormously abused by us. It is true, our *αλεκτρομαχία*, or the massacre of Shrove Tuesday, is now in a declining way; and, in a few years, it is to be hoped, will be totally disused: but the cock-pit still continues a reproach to the humanity of Englishmen; and to their religion, the purest, the tenderest, and most compassionate, of all others, not excepting even the Brachmannic.

It is unknown when the pitched battle first entered England; but it was probably brought thither by the Romans. The bird was here before Cæsar's arrival; but no notice of his fighting occurs earlier than the time of William Fitz-Stephen, who wrote the life of archbishop Becket, some time in the reign of Henry II. and describes the cocking as a sport of school-boys on Shrove Tuesday. From this time at least, the diversion, however absurd, and even impious, was continued amongst us. It was followed, though disapproved and prohibited by Edward III.; also in the reign of Henry VIII.; and A. D. 1569. It has by some been called a *royal diversion*; and, as every one knows, the cock-pit at Whitehall was erected by a crowned head, for the more magnificent celebration of it. There was another pit in Drury-lane, and another in Javin-street. It was prohibited, however, by one of Oliver's acts, March 31st 1764. What aggravates the reproach and disgrace upon Englishmen, are those species of fighting which are called the

Cock-pit
↓
Cocker-
mouth.

Battle-royal and the *Welsh-main*, known nowhere in the world but there; neither in China, nor in Persia, nor in Malacca, nor among the savage tribes in America. These are scenes too bloody as almost to be too shocking to relate; and yet, as many may not be acquainted with the horrible nature of them, it may be proper for the excitement of our aversion and detestation to describe them in a few words. In the former, an unlimited number of fowls are pitted; and when they have slaughtered one another for the diversion (*Du bout!*) of the otherwise generous and humane Englishman, the fingle surviving bird is to be esteemed the victor, and carries away the prize. The *Welsh-main* consists, we will suppose of 16 pair of cocks; of these, the 16 conquerors are pitted a second time; the 8 conquerors of these are pitted a third time; the 4 conquerors the fourth time; and lastly, the two conquerors of these are pitted the fifth time; so that, (incredible barbarity!) 31 cocks are sure to be most inhumanely murdered for the sport and pleasure, the noise and nonsense, nay (we may say) the profane cursing and swearing, of those who have the effrontery to call themselves, with all these bloody doings, and with all this impiety about them, *Christians*.

COCK-PIT, of a ship of war, the apartment of the surgeon and his mates; being the place where the wounded men are dressed in time of battle, or otherwise. It is situated under the lower deck.

COCKSWAIN, or **COXEN**; an officer on board a man of war, who has the care of the barge, and all things belonging to it, and must be already with his crew to man the boat on all occasions: he sits at the stern of the boat, and steers.

COCKERMOUTH, a town of Cumberland in England, situated in W. Long. 3. 12. N. Lat. 54. 35. It is a large town irregularly built, with broad streets. It is washed by the Derwent on the western side; divided in two by the Cocker; and the parts are connected by a stone-bridge of one single arch. The number of inhabitants is between three and four thousand: the manufactures are shalloons, worsted stockings, and hats; the last exported from Glasgow to the West Indies. It is a borough-town, and the right of voting is vested by burges tenure in certain houses: this is also the town where the county elections are made.—Here is a castle seated on an artificial mount on a bank above the Derwent. It is a square building, and strengthened with several square towers: on each side of the inner gate are two deep dungeons capable of holding 50 persons in either; they are vaulted at top, and have only a small opening in order to lower through it the unhappy prisoners into this dire prison; and on the outside of each is a narrow slit with a slope from it, down which were shot the provisions allotted for the wretched inhabitants. This castle was founded by Waldo, first lord of Alderdale, and son of Gospatrick earl of Northumberland, cotemporary with William the Conqueror. Waldo resided first at Papcastle, which he afterwards demolished; and with the materials built that at Cocker-mouth, where he and his family long resided; but several arms over the gate-way, which Camden says are those of the *Mulsons*, *Hunfravilles*, *Lucies*, and *Piercies*, evince it to have belonged in later times to

those families. It appears that it was first granted by Edward II. to Anthony de Lucie, son of Thomas de Multon, who had assumed that name, because his mother was daughter and co-heiress to Richard de Lucie; and afterwards, by marriages, this castle and its honours descended to the Hunfravilles, and finally to the Piercies. In 1658, it was garrisoned for the king; and being besieged and taken by the rebels, was burnt, and never afterwards repaired.

COCKET, is a seal belonging to the king's custom-house, or rather a scroll of parchment sealed and delivered by the officers of the customs to merchants, as a warrant that their merchandises are customed.

It is also used for the office where goods transported were first entered, and paid their custom, and had a cocket or certificate of discharge.

COCKLE, in ichthyology. See **CARDIUM**.

COCOA, in botany. See **COCOS**.

COCONATO, a town of Piedmont in Italy, famous for being the birth-place of Columbus, who first discovered America: E. Long. 8. 0. N. Lat. 44. 50.

COCOS, the **COCOA-NUT TREE**; a genus of the order of palmæ, belonging to the monœcia class of plants. There is only one species known, which is cultivated in both the Indies, and is of the greatest use to the inhabitants. It is supposed to be a native of the Maldivæ and some desert islands in the East Indies; and from thence to have been transported to all the warm parts of America; for it is not found in any of the inland parts, nor any where far distant from settlements. The tree frequently rises 60 feet high. The body of the trunk, which generally leans to one side, occasioned, as is supposed, by the great weight of nuts it sustains when young, is the exact shape of an apothecary's large iron pestle, being of an equal thickness at top and at bottom, but somewhat smaller in the middle; its colour is of a pale brown throughout, and the bark smooth. The leaves or branches are often 14 or 15 feet long, about 28 in number, winged, of a yellow colour, straight and tapering. The pinne, or partial leaves are green, often three feet long next the trunk, but diminishing in length toward the extremity of the branches. The branches are fastened at top by brown stringy threads that grow out of them, of the size of ordinary pack-thread, and are interwoven like a web. The nuts hang at the top of the trunk, in clusters of a dozen each. Each nut, next the stem, has three holes closely stopped; one of them being wider, and more easily penetrated than the rest. When the kernel begins to grow, it incrusts the inside of the nut in a bluish, jelly-like substance; as this grows harder, the inclosed liquid, distilled into the nut from the roots, becomes somewhat acid; and the kernel, as the nut ripens, becomes still more solid; and at length lines the whole inside of the nut for above a quarter of an inch thick, being as white as snow, and of the flavour of an almond. The quantity of liquor in a full grown nut is frequently a pint and upwards. The husky tegument of the nut consists of strong, tough, stringy filaments, which, when removed from the fruit, resemble coarse oakum, and may perhaps be conveniently enough used as such. The shells of these nuts, being tipped with silver, are frequently used for drinking bowls. The bark of the tree may be wrought into

Cocket
↓
Cocos.

into cordage, and the leaves into baskets, brooms, hammocks in form of nets, mats, sacks, and other useful utensils. The liquor contained in the shell is a moist cooling, wholesome beverage in those sultry climates, and the white kernel a moist agreeable food. The Maldivé cocoa-nut is esteemed, by the inhabitants of these islands, as a powerful antidote against the bites of serpents and other poisons. The cocoa-nut tree is propagated by planting the nuts; which, in six weeks or two months time, will come up, provided they are fresh and thoroughly ripe; but this is what few of them are when brought into this country; for they always gather them before they are ripe, that they may keep during their passage. The best way, therefore, would be to gather such nuts as are thoroughly ripe in their native country, and plant them in a tub of dry sand, in order to keep them from the vermin during their passage. Here they will frequently sprout, which will be an advantage, as they may then be immediately planted in pots of earth, and plunged in the bark-stove.

COCTION, a general term for all alterations made in bodies by the application of fire or heat.

COCYTUS, one of the rivers of hell, according to the theology of the poets. It has its name *αἰὼς τοῦ κλάυου*, from groaning and lamenting. Hence Milton,

*Cocytus nam'd of lamentation loud,
Heard on the woeful stream.*

It was a branch of the river Styx; and flowed, according to Horace, with a dull and languid stream.

COD, in ichthyology. See GADUS, and FISHERY.

COD is also a term used, in some parts of the kingdom, for a pod. See POD.

COD-GAPE, a promontory on the coast of New England, near the entrance of Boston harbour, W. Long. 69. 50. N. Lat. 42. 0.

CODDY-MODDY, the English name of a species of LARUS.

CODE, *codex*, a collection of the laws and constitutions of the Roman emperors, made by order of Justinian.

The code is accounted the second volume of the civil law, and contains twelve books; the matter of which is nearly the same with that of the digests, especially the first eight books: but the style is neither so pure, nor the method so accurate, as that of the digests; and it determines matters of daily use, whereas the digests discuss the more abstruse and subtle questions of the law, giving the various opinions of the ancient lawyers. Although Justinian's code is distinguished by the appellation of *code*, by way of eminence, yet there were codes before his time; such were, 1. The Gregorian code, and Hermogenean code; collections of the Roman laws, made by two famous lawyers, Gregorius and Hermogenes, which included the constitutions of the emperors from Adrian to Dioclesian and Maximinus. 2. The Theodosian code, comprised in 16 books, formed out of the constitutions of the emperors from Constantine the Great to Theodosius the Younger: this was observed almost over all the west, till it was abrogated by the Justinian code. There are also several later codes, particularly the ancient Gothic, and those of the French kings; as the

code of Euridic, code-Lewis, code-Henry, code-Marchande, code des Eaux, &c.; and the present king of Prussia has lately published a code, which comprizes the laws of his kingdom in a very small volume.

CODEX, in antiquity, denotes a book or tablet on which the ancients wrote. It was of the bark of a tree, of ivory, of parchment, or of paper.

CODIA, among botanists, signifies the head of any plant, but more particularly a poppy-head; whence its syrup is called *diacodum*.

CODICIL, is a writing, by way of supplement to a will, when any thing is omitted that the testator would have added, or wants to be explained, altered, or recalled.

CODLIN, an apple useful in the kitchen, being the most proper for baking.

CODLING, an appellation given to the cod-fish when young. See GADUS.

CODON, *Καδων*, in antiquity, a cymbal, or rather little brass bell, resembling the head of a poppy. They were fastened to the trappings and bridles of horses.

CODRINGTON (Christopher,) a brave English officer, and not less distinguished for his learning and benevolence; was born at Barbadoes in the year 1668, and educated at Oxford; after which he betook himself to the army, and, by his merit and courage, soon recommending himself to the favour of king William, was made a captain in the first regiment of foot-guards. He was at the siege of Namur in 1695; and, upon the conclusion of the peace of Ryfwick, was made captain-general and governor in chief of the Leeward and Caribbee islands. However, in 1701, several articles were exhibited against him to the house of commons in England; to which he published a distinct and particular answer, and was honourably acquitted of all imputations. In 1703, he shewed great bravery at the attack of Guadaloupe: but at last he resigned his government, and lived a studious retired life; for a few years before his death, he chiefly applied himself to church-history and metaphysics. He died at Barbadoes, on the 7th of April 1710, and was buried there the day following; but his body was afterwards brought over to England, and interred, on the 19th of June 1716, in the chapel of All-Souls College, Oxford. By his last will, he bequeathed his plantations in Barbadoes, and part of the island of Barbuda, to the society for propagating the gospel in foreign parts; and left a noble legacy to All-Souls College, of which he had been a fellow. This legacy consisted of his library, which was valued at 6000 l.; and 10,000 l. to be laid out, 6000 in building a library, and 4000 in furnishing it with books. He wrote some of the poems in the *Musæ Anglicanæ*, printed at London in 1741.

CODRUS, the last king of the Athenians, fell in the defence of his country against the Heraclides. See ATTICA, n^o 26.

COECUM, or BLIND-GUT. See ANATOMY, n^o 354.

Dr Musgrave gives us an account, in the Philosophical Transactions, of the cœcum of a dog being cut out, without any prejudice to the animal. Mr Giles gives us another of the cœcum of a lady being distended, so as to form a tumour that held almost three chopins of a thin, greyish, almost liquid substance, of which she died. And Mr Knowler a third, of a boy's cœcum being

Coefficients

Coenobium

being vastly extended and stuffed with cherry-stones, which likewise proved mortal.

COEFFICIENTS, in algebra, are such numbers, or known quantities, as are put before letters or quantities, whether known or unknown, and into which they are supposed to be multiplied. Thus, in $3x$, ax , or bx ; 3 , a and b , are the coefficients of x ; and in $6a$, $9b$, 6 , and 9 , are the coefficients of a and b . See **ALGEBRA**.

COELESTIAL, or **CELESTIAL**, in general, denotes any thing belonging to the heavens: thus we say, celestial observations, the celestial globe, &c.

COELIAC ARTERY, in anatomy, that artery which issues from the aorta, just below the diaphragm. See **ANATOMY**, n^o 387. f.

COELIAC Passion. See (the *Index* subjoined to) **MEDICINE**.

COELIAC Vein, in anatomy, that running through the intestinum rectum, along with the coeliac artery.

COELOMA, among physicians, a hollow ulcer, seated in the tunica cornea of the eye.

COELUS, heaven, in Pagan mythology, the son of Æther and Dies, or Air and Day. According to Hesiod, he married Terra, or the Earth; on whom he begat Oura, or the Mountains, the Ocean, &c. But having at length imprisoned the Cyclops, who were also his children, his wife, being offended, incited her son Saturn to revenge the injury done to his brothers; and, by her assistance, he bound and castrated Coelus, when the blood that flowed from the wound produced the three furies, the giants, and the wood-nymphs; and the genital parts being thrown into the sea, impregnated the waters, and formed the goddess Venus. This deity was called by the Greeks *Uranus*.

COEMETERY. See **CEMETERY**.

COENOBITE, a religious who lives in a convent, or in community, under a certain rule; in opposition to anachoret, or hermit, who lives in solitude. The word comes from the Greek *κοινος*, *communis*; and *βίος*, *vita*, life. Cassian makes this difference between a *convent* and a *monastery*, that the latter may be applied to the residence of a single religious, or recluse; whereas the *convent* implies *coenobites*, or numbers of religious living in common. Fleury speaks of three kinds of monks in Egypt; *anachorets*, who live in solitude; *coenobites*, who continue to live in community; and *sarabaites*, who are a kind of monk-errant, that stroll from place to place. He refers the institution of coenobites to the times of the apostles, and makes it a kind of imitation of the ordinary lives of the faithful at Jerusalem. Though St Pachomius is ordinarily owned the institutor of the coenobite life; as being the first who gave a rule to any community.

COENOBIVM, *κοινωβιον*, the state of living in a society, or community, where all things are common. Pythagoras is thought to be the author or first institutor of this kind of life; his disciples, though some hundreds in number, being obliged to give up all their private estates, in order to be annexed to the joint stock of the whole. The Essenians among the Jews, and Platonists, are said to have lived in the same manner. Many of the Christians also have thought this the most perfect kind of society, as being that in which Christ and his apostles chose to live.

Coesfeldt

Coffea

COESFELDT, a town of Germany, in Westphalia, and in the territories of the bishop of Munster, where he often resides. It is near the river Burkel, E. Long. 64. 2. N. Lat. 51. 58.

COEVORDEN, one of the strongest towns in the United Provinces, in Overijssel, fortified by the famous Cohorn. It was taken by the bishop of Munster, 1673; and the Dutch retook it the same year. It is surrounded by a morass. E. Long. 6. 41. N. Lat. 52. 40.

COFFEA, the **COFFEE-TREE**; a genus of the monogynia order, belonging to the pentandria class of plants. There is but one species, supposed to be a native of Arabia Felix. It seldom rises more than 16 or 18 feet in height; the main stem grows upright, and is covered with a light brown bark; the branches are produced horizontally and opposite, crossing each other at every joint; so that every side of the tree is fully garnished with them, and they form a sort of pyramid. The leaves also stand opposite; and, when fully grown, are about four or five inches long, and two broad in the middle, decreasing toward each end; the borders are waved, and the surface is of a lucid green. The flowers are produced in clusters at the root of the leaves, sitting close to the branches; they are tubulous, and spread open at the top, where they are divided into five parts; they are of a pure white, and have a very grateful odour, but are of short duration. The fruit, which is the only useful part, resembles a cherry. It grows in clusters, and is ranged along the branches under the axillæ of the leaves of the same green as the laurel, but something longer. When it comes to be of a deep red, it is gathered for the mill, in order to be manufactured into those *coffee-beans* now so generally known. The mill is composed of two wooden rollers furnished with iron plates 18 inches long, and ten or twelve in diameter. These moveable rollers are made to approach a third which is fixed, and which they call the *chops*. Above the rollers is a hopper, in which they put the coffee, from whence it falls between the rollers and the chops, where it is stripped of its first skin, and divided into two parts, as may be seen by the form of it after it has undergone this operation; being flat on the one side, and round on the other. From this machine it falls into a brass sieve, where the skin drops between the wires, while the fruit slides over them into baskets placed ready to receive it: it is then thrown into a vessel full of water, where it soaks for one night, and is afterwards thoroughly washed. When the whole is finished, and well dried, it is put into another machine called the *peeling-mill*. This is a wooden grinder, turned vertically upon its treadle by a mule or horse. In passing over the coffee it takes off the parchment, which is nothing but a thin skin that detaches itself from the berry in proportion as it grows dry. The parchment being removed, it is taken out of this mill to be put into another, which is called the *winnowing-mill*. This machine is provided with four pieces of tin fixed upon an axle, which is turned by a slave, with considerable force; and the wind that is made by the motion of these plates clears the coffee of all the pellicles that are mixed with it. It is afterwards put upon a table, where the broken berries, and

Coffee.

and any filth that may remain among them, are separated by negroes, after which the coffee is fit for sale.

The coffee-tree is cultivated in Arabia, Persia, the East-Indies, the Isle of Bourbon, and several parts of America. It is also raised in botanic gardens in several parts of Europe. Prince Eugene's garden at Vienna produced more coffee than was sufficient for his own consumption. It delights particularly in hills and mountains, where its root is almost always dry, and its head frequently watered with gentle showers. It prefers a western aspect, and ploughed ground without any appearance of grass. The plants should be placed at eight feet distance from each other, and in holes twelve or fifteen inches deep. If left to themselves, they would rise to the height of 16 or 18 feet, as already observed; but they are generally stunted to five, for the convenience of gathering their fruit with the greater ease. Thus dwarfed, they extend their branches so, that they cover the whole spot round about them. They begin to yield fruit the third year, but are not in full bearing till the fifth. With the same infirmities that most other trees are subject to, these are likewise in danger of being destroyed by a worm, or by the scorching rays of the sun. The hills where the coffee-trees are found, have generally a gravelly or chalky bottom. In the last, it languishes for some time and then dies: in the former, its roots, which seldom fail of striking between stones, obtain nourishment, and keep the tree alive, and fruitful for 30 years. This is nearly the period for plants of the coffee-tree. The proprietor, at the end of this period, not only finds himself without trees, but has his land reduced, that it is not fit for any kind of culture; and unless he is so situated, that he can break up a spot of virgin land, to make himself amends for that which is totally exhausted by the coffee-tree, his loss is irreparable.

The coffee produced in Arabia is found so greatly to excel that raised in the American plantations or elsewhere, that the cultivation of the tree is now but seldom practised in any of the British colonies. Large plantations of this kind were formerly made, in some of them; and it was proposed to the parliament to give a proper encouragement for cultivating this commodity there, so as to enable the planters to undersell the importers from Arabia. Accordingly, there was an abatement of the duty payable on all coffee imported from our colonies in America, which at that time was supposed to be sufficient encouragement for this kind of commerce; but the inferiority of the American coffee to the Arabian, hath almost ruined the project. Mr Miller proposes some improvements in the method of cultivation. According to him, the trees are planted in too moist a soil, and the berries are gathered too soon. They ought, he says, to be permitted to remain on the trees till their skins are shrivelled, and they fall from the trees when shaken. This will indeed greatly diminish their weight, but the value of the commodity will thereby be increased to more than double of that which is gathered sooner. In Arabia, they always shake the berries off the trees, spreading cloths to receive them, and only take such as readily fall at each time. Another cause may be the method of drying the berries. They are, he ob-

serves, very apt to imbibe moisture, or the flavour of any thing placed near them. A bottle of rum placed in a closet, in which a canister of coffee-berries closely stopped was standing on a shelf at a considerable distance, in a few days fo impregnated the berries as to render them very disagreeable; the same hath also happened by a bottle of spirit of wine standing in the same closet with coffee and tea, both which were in a few days spoiled by it. Some years ago, a coffee ship from India had a few bags of pepper put on board, the flavour of which was imbibed by the coffee, and the whole cargo spoiled. For these reasons, Mr Miller directs that coffee-berries should never be brought over in ships freighted with rum, nor laid to dry in the houses where figs are boiled or rum distilled. When they are fully ripe, they should be shaken off when the trees are perfectly dry, and spread upon cloths in the sun to dry, carrying them every evening under cover, to prevent the dews or rain from falling on them. When perfectly dry, they should have their outer skins beaten off, and then be carefully packed up in cloths or bags three or four times double.

The coffee-tree, as we have already observed, is sometimes cultivated in European gardens; but for this it requires the assistance of a stove. It makes a fine appearance at all seasons of the year, (being an evergreen), but especially when in flower, and when the berries are red, which is generally in the winter, so that they continue a long time in that state. It is propagated from the berries; but they must be planted immediately when gathered from the tree, for they lose their vegetative quality in a very short time, when sent abroad by the post they have constantly failed in those that have been a fortnight on their journey; so that where these trees are desired, the young plants must be sent, if it be at any distance from the place where they grow. The fresh berries may be planted in small pots, and plunged into a hot-bed of tanners bark. If the bed be of a proper temperature, the young plants will appear in a month or five weeks time; and in six weeks more, will be ready for transplanting into separate pots. During summer, they must be frequently watered; but not in too great plenty, otherwise the roots will be apt to rot. The first sign of the plants being disordered is their leaves sweating out a clammy juice; after which they are over-run with insects, that cannot be destroyed till the plants have recovered their health; so that on the first appearance of these insects, the trees should be removed into fresh earth, and all possible care taken to recover them. The disorders incident to them, generally proceed either from their having been put into large pots, or from the earth about them being too stiff, or over-watered. The most proper soil for them, is that of a kitchen garden, which is naturally loose, and not subject to bind, especially if it has constantly been well wrought and dunged.

COFFEE also denotes a kind of drink, prepared from these berries; very familiar in Europe for these 80 years, and among the Turks for 150.

Its original is not well known. Some ascribe it to the prior of a monastery; who, being informed by a goat-herd

Coffee.

goat-herd that his cattle sometimes browsing on the tree would wake and caper all night, became curious to prove its virtue: accordingly, he first tried it on his monks, to prevent their sleeping at mattins. Others, from Sehehabeddin, refer the invention of coffee to the Persians: from whom it was learned in the 15th century by Gemaleddin, musli of Aden, a city near the mouth of the red sea; and who having tried its virtues himself, and found that it dissipated the fumes which oppressed the head, inspired joy, opened the bowels, and prevented sleep, without being incommoded by it, recommended it first to his disciples, with whom he used to spend the night in prayer. Their example brought coffee into vogue at Aden; the professors of the law for study, artificers to work, travellers to walk in the night, in fine every body at Aden, drank coffee. Hence it passed to Mecca; where first the devotees, then the rest of the people, took it. From Arabia Felix it passed to Cairo. In 1511, Kahie Beg prohibited it, from a persuasion that it inebriated, and inclined to things forbidden. But Sultan Causim immediately after took off the prohibition; and coffee advanced from Egypt to Syria and Constantinople. The dervises declaimed against it from the Alcoran, which declares, that coal is not of the number of things created by God for food. Accordingly, the musli ordered the coffee-houses to be shut; but his successor declaring coffee not to be coal, they were opened again. During the war in Candia, the assemblies of news-mongers making too free with state affairs, the grand Vizier Cuprolì suppressed the coffee-houses at Constantinople; which suppression, though still on foot, does not prevent the public use of the liquor there. Thevenot, the traveller, was the first who brought it into France; and a Greek servant, named *Pasqua*, brought into England by Mr Dan. Edwards, a Turkey merchant, in 1652, to make his coffee, first set up the profession of *coffee-man*, and introduced the drink into this island.

The word *coffee* is originally Arabic: the Turks pronounce it *cabehh*, and the Arabians *cabwah*; which some authors maintain to be a general name for any thing that takes away the appetite, others for any thing that promotes appetite, and others again for any thing that gives strength and vigour.—The Mahometans, it is observed, distinguish three kinds of *cabwah*. The first is wine, or any liquor that inebriates; the second is made of the pods that contain the coffee-berry; this they call the *Sultan's coffee*, from their having first introduced it on account of its heating less than the berry, as well as its keeping the bowels open: the third is that made with the berry itself, which alone is used in Europe, the pods being found improper for transportation. Some Europeans who imported the pods called them the *flower of the coffee-tree*. The deep brown colour of the liquor occasioned its being called *syrup of the Indian mulberry*, under which specious name it first gained ground in Europe.

The preparation of coffee consists in roasting, or giving it a just degree of torrefaction on an earthen or metalline plate, till it have acquired a brownish hue equally deep on all sides. It is then ground in a mill, as much as serves the present occasion. A proper quantity of water is next boiled, and the ground coffee put

into it. After it has just boiled, it is taken from the fire, and the decoction having stood a while to settle and fine, they pour or decant it into dishes. The ordinary method of roasting coffee amongst us is in a tin cylindrical box full of holes, through the middle whereof runs a spit: under this is a femicircular hearth, whereon is a large charcoal-fire: by help of a jack the spit turns swift, and so roasts the berry; being now and then taken up to be shaken. When the oil rises, and it is grown of a dark brown colour, it is emptied into two receivers made with large hoops, whose bottoms are iron plates: there the coffee is shaken, and left till almost cold; and if it look bright and oily, it is a sign it is well done.

Very different accounts have been given of the medicinal qualities of this berry. To determine its real effects on the human body, Dr Percival has made several experiments, the result of which he gives in the following words: "From these observations we may infer, that coffee is slightly astringent, and antiseptic; that it moderates alimentary fermentation, and is powerfully sedative. Its action on the nervous system probably depends on the oil it contains; which receives its flavour, and is rendered milky empyreumatic, by the process of roasting. Neuman obtained by distillation from one pound of coffee, five ounces five drachms and a half of water, six ounces and half a drachm of thick fetid oil, and four ounces and two drachms of a caput mortuum. And it is well known, that rye, torrefied with a few almonds, which furnish the necessary proportion of oil, is now frequently employed as a substitute for these berries."

"The medicinal qualities of coffee seem to be derived from the grateful sensation which it produces in the stomach, and from the sedative powers it exerts on the *vis vitæ*. Hence it assists digestion, and relieves the head-ach; and is taken in large quantities, with peculiar propriety, by the Turks and Arabians; because it counteracts the narcotic effects of opium, to the use of which those nations are much addicted."

"In delicate habits, it often occasions watchfulness, tremors, and many of those complaints which are denominated nervous. It has been even suspected of producing palsies; and from my own observation, I should apprehend, not entirely without foundation. Slare affirms, that he became paralytic by the too liberal use of coffee, and that his disorder was removed by abstinence from that liquor."

"The following curious and important observation is extracted from a letter with which I was honoured by Sir John Pringle, in April 1773: "On reading your section concerning coffee, one quality occurred to me which I had observed of that liquor, confirming what you have said of its sedative virtues. It is the best abater of the paroxysms of the periodic asthma that I have seen. The coffee ought to be of the best Mocco, newly burnt, and made very strong immediately after grinding it. I have commonly ordered an ounce for one dish; which is to be repeated fresh after the interval of a quarter or half an hour; and which I direct to be taken without milk or sugar. The medicine in general is mentioned by Musgrave, in his treatise *De arthritide anomala*; but I first heard of it from a physician in this place, who having once practised

Coffee.

practised it in Litchfield, had been informed by the old people of that place, that Sir John Floyer, during the latter year of his life, kept free from, or at least lived easy under, his asthma, from the use of very strong coffee. This discovery, it seems, he made after the publication of his book upon that disease." Since the receipt of that letter, I have frequently directed coffee in the asthma with great success."

COFFER, in architecture, a square depression or sinking in each interval between the modillions of the Corinthian cornice; ordinarily filled up with a rose; sometimes with a pomegranate, or other enrichment.

COFFER, in fortification, denotes a hollow lodgement, athwart a dry moat, from 6 to 7 feet deep, and from 16 to 18 broad; the upper part made of pieces of timber raised two feet above the level of the moat; which little elevation has hurdles laden with earth for its covering, and serves as a parapet with embrasures: the coffer is nearly the same with the caponiere, excepting that this last is sometimes made beyond the counterscarp on the glacis; and the coffer always in the moat taking up its whole breadth, which the caponiere does not. It differs from the traverse and gallery, in that these latter are made by the besiegers, and the coffer by the besieged. The besieged generally make use of coffers to repulse the besiegers when they endeavour to pass the ditch. To save themselves from the fire of these coffers, the besiegers throw up the earth on that side towards the coffer.

COFFERER of the KING'S HOUSEHOLD, a principal officer in the court, next under the comptroller, who, in the counting-house, and elsewhere at other times, has a special charge and oversight of other officers of the house, for their good demeanor and charge in their offices; to all which he pays their wages.

COFFIN, the chest in which dead bodies are put into the ground.

The sepulchral honours paid to the manes of departed friends, in ancient times, demand attention, and are extremely curious. Their being *put into a coffin* has been particularly considered as a mark of the highest distinction. With us the poorest people have their coffins. If the relations cannot afford them, the parish is at the expence. On the contrary, in the east they are not at all made use of in our times; Turks and Christians, as Thevenot assures us, agree in this. The ancient Jews seem to have buried their dead in the same manner: neither was the body of our Lord, it should seem, put into a coffin; nor that of Elisha, 2 Kings xiii. 21. whose bones were touched by the corpse that was let down a little after into his sepulchre. However, that they were anciently made use of in Egypt, all agree; and antique *coffins of stone*, and *scamora-wood*, are still to be seen in that country; not to mention those said to be made of a kind of pasteboard; formed by folding or gluing cloth together a great many times, curiously plaited, and then painted with hieroglyphics. Its being an ancient Egyptian custom, and not practised in the neighbouring countries, were, doubtless, the cause that the sacred historian expressly observes of Joseph, that he

both being managements peculiar to the Egyptians.

Bishop Patrick, in his commentary on this passage, takes notice of these Egyptian coffins of sycamore wood, and of pasteboard; but he doth not mention the contrary usage in the neighbouring countries, which was requisite, one might suppose, in order fully to illustrate the place: but even this perhaps would not have conveyed the whole idea of the sacred author. Maillet apprehends that all were not inclosed in coffins who were laid in the Egyptian repositories of the dead; but that it was an honour appropriated to persons of figure: for after having given an account of several riches found in those chambers of death, he adds †, "But it must not be imagined that † Let. vii. p. 281. the bodies deposited in these gloomy apartments were all inclosed in *chests*, and placed in niches. The greatest part were simply embalmed and swathed after that manner which every one hath some notion of; after which they laid them one by the side of another without any ceremony. Some were even laid in these tombs without any embalming at all; or such a slight one, that there remains nothing of them in the linen in which they were wrapped, but the bones, and those half rotten. It is probable, that each considerable family had one of these burial-places to themselves; that the niches were designed for the bodies of the heads of the families; and that those of their domestics or slaves had no other care taken of them than the laying them on the ground, after having been embalmed, or even without that; which, without doubt, was also all that was done even to the heads of families of less distinction." After this he gives an account of a way of burial, practised anciently in that country, which had been but lately discovered; and which consisted in placing the bodies, after they were swathed, upon a layer of charcoal, and covering them with a mat, under a depth of sand of seven or eight feet.

That *coffins* then were not universally used in Egypt, is undoubted from these accounts; and probably they were only persons of distinction who were buried in them. It is also reasonable to believe, that in times so remote as that of Joseph, they might be much less common than afterwards; and consequently, that Joseph's being put in a coffin in Egypt might be mentioned with a design to express the great honours which the Egyptians did him at his death, as well as in life, being interred after the most sumptuous manner of the Egyptians, *embalmed*, and *put into a coffin*. Agreeably to this, the Septuagint version, which was made for Egyptians, seems to represent coffins as a mark of grandeur. Job xxi. 32.

It is no objection to this account, that the widow of Nain's son is represented as carried forth to be buried in a *osq*, or "on a bier:" for the present inhabitants of the Levant, who are well known to lay their dead bodies in the earth uninclosed, carry them frequently out to burial in a kind of coffin. So Dr Russell, in particular, describes the bier used for the Turks at Aleppo, as a kind of coffin much in the form of ours, only that the lid rises with a ledge in the middle. Christians indeed, as he tells us, are carried to the grave on an open bier: but as the most common kind of bier resembles our coffins, that used

* Gen. l. 26. was not only embalmed, but put into a coffin too *;

Cogitation by the people of Nain might very possibly be of the same kind; in which case the word *cogitatio* was very proper.

Cohesion.

COGITATION, a term used by some for the act of thinking.

COGNAC, a town of France in Angoumois, with a castle, where Francis I. was born. It is seated on the river Charante, in a very pleasant country, abounding in wine, and remarkable for excellent brandy. W. Long. o. 10. N. Lat. 45. 42.

COGNATE, in Scots law, any male relation thro' the mother.

COGNATION, in the civil law, a term for that line of consanguinity which is between males and females, both descended from the same father; as agnation is for the line of parentage between males only descended from the same flock.

COGNI, an ancient and strong town of Caramania in Turkey in Asia, and the residence of a beglerbeg. It is seated in a pleasant country, abounding in corn, fruits, pulse, and cattle. Here are sheep whose tails weigh 30 pounds. E. Long. 32. 56. N. Lat. 37. 56.

COGNITIONIS CAUSA, in Scots law. When a creditor charges the heir of his debtor to enter, in order to constitute the debt against him, and the heir renounces the succession, the creditor can obtain no decret of constitution of that debt against the heir; but only a decret subjecting the *hereditas jacens*, or the estate which belonged to the debtor, to his diligence: and this is called a decret *cognitionis causa*.

COGNIZANCE, or **CONNUSSANCE**, in law, has divers significations. Sometimes it is an acknowledgement of a fine, or confession of something done; sometimes the hearing of a matter judicially, as to take cognizance of a cause; and sometimes a particular jurisdiction, as cognizance of pleas is an authority to call a cause or plea out of another court, which no person can do but the king, except he can show a charter for it. This cognizance is a privilege granted to a city or a town to hold plea of all contracts, &c. within the liberty; and if any one is impleaded for such matters in the courts at Westminster, the mayor, &c. of such franchise may demand cognizance of the plea, and that it may be determined before them.

COGNIZANCE is also used for a badge on a waterman's, or serving-man's sleeve, which is commonly the giver's crest, whereby he is decreed to belong to this or that nobleman or gentleman.

COGS, or **COGGLES**, a kind of flat-bottomed boats used on rivers.

COHABITATION, denotes the state of a man and a woman who live together without being legally married. By the common law of Scotland, cohabitation for year and day, or a complete twelvemonth, is deemed equivalent to matrimony.

CO-HEIR, one who succeeds to a share of an inheritance, to be divided among several.

COHESION, one of the four species of attraction, denoting that force by which the parts of bodies adhere or stick together.

This power was first considered by Sir Isaac Newton as one of the properties essential to all matter, and the cause of all that variety we observe in the texture of different terrestrial bodies. He did not, however,

absolutely determine that the power of cohesion was an immaterial one; but thought it might possibly arise, as well as that of gravitation, from the action of an ether. His account of the original constitution of matter is as follows: "It seems probable, that God in the beginning formed *matter* in solid, massy, impenetrable, moveable particles; of such sizes, figures, and other properties, and in such proportion to space, as most conduced to the end for which he formed them: and that these primitive particles being solid, are incomparably harder than any porous bodies composed of them; even so very hard as never to wear or break in pieces; no ordinary power being able to divide what God himself made one at the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of all things depending on them would be changed. Water and earth composed of old worn particles and fragments of particles, would not now be of the same texture with water and earth composed of entire particles in the beginning. And therefore, that nature may be lasting, the changes of corporeal things are to be placed in the various separations and new associations and motions of these permanent particles; compound bodies being apt to break, not in the midst of solid particles, but where these particles are laid together and touch in a few points." It seems farther, "That these particles have not only a *vis inertiae*, accompanied with such passive laws of motion as naturally result from that force; but also that they are moved by certain active principles, such as that of gravity, and that which causeth fermentation and the cohesion of bodies. These principles are to be considered not as occult qualities, supposed to result from the specific forms of things, but as general laws of nature by which the things themselves are formed; their truth appearing to us by phenomena, though their cause is not yet discovered."

The general law of nature, by which all the different bodies in the universe are composed, according to Sir Isaac Newton, is that of attraction: *i. e.* "Every particle of matter has an attractive force, or a tendency to every other particle; which power is strongest in the point of contact, and suddenly decreases, inasmuch that it acts no more at the least sensible distance; and at a greater distance is converted into a repellent force, whereby the parts fly from each other. On this principle of attraction may we account for the cohesion of bodies, otherwise inexplicable."

"The smallest particles may cohere by the strongest attractions, and compose bigger particles of weaker virtue; and many of these may cohere, and compose bigger particles, whose virtue is still less; and so on for divers successions, until the progression end in the biggest particles, on which the operations in chemistry, and the colours of natural bodies, depend; and which, by cohering, compose bodies of a sensible magnitude. If the body is compact, and bends or yields inward to pressure without any sliding of its parts, it is hard and elastic; returning to its figure with a force arising from the mutual attraction of its parts. If the parts slide from one another, the body is malleable or soft."

Cohesion.

2 His account of the original constitution of matter.

3 Attraction, the general law of nature.

4 Formation of particles of different sizes.

5 Distinction of bodies into hard, soft, humid &c.

1 Considered by Sir Isaac Newton as an essential property of matter.

Cohesion.

If they slip easily, and are of a fit size to be agitated by heat, and the heat is great enough to keep them in agitation, the body is fluid; and if it be apt to stick to things, it is humid; and the drops of every fluid affect a round figure by the mutual attractions of their parts, as the globe of the earth and sea affects a round figure from the mutual attraction and gravity of its parts.

“ Since metals dissolved in acids attract but a small quantity of the acid, their attractive force reaches but to a small distance. Now, as in algebra, where affirmative quantities cease, there negative ones begin; so in mechanics, where attraction ceases, there a repulsive virtue must succeed. That there really is such a virtue seems to follow from the reflections and inflections of the rays of light; the rays being repelled by bodies in both these cases without the immediate contact of the reflecting or inflecting body. The same thing seems also to follow from the emission of light; a ray, as soon as shaken off from a body by the vibrating motion of the parts of the body, and got beyond the reach of attraction, being driven away with exceeding great velocity: for that force which is sufficient to turn it back in reflection may be sufficient to emit it. From the same repelling power it seems to be that flies walk upon the water without wetting their feet; that the object-glasses of long telescopes lie upon one another without touching; and that dry powders are difficultly made to touch one another so as to stick together, without melting them or wetting them with water, which, by exhaling, may bring them together.

“ The particles of all hard homogeneous bodies which touch one another, cohere with a great force: to account for which, some philosophers have recourse to a kind of hooked atoms, which in effect is nothing else but to beg the question. Others imagine, that the particles of bodies are connected by rest, *i. e.* in effect by nothing at all; and others, by conspiring motions, *i. e.* by a relative rest among themselves. For myself, it rather appears to me, that the particles of bodies cohere by an attractive force, whereby they tend mutually to each other.”

From this account of the formation and constitution of bodies, we can conclude nothing, except that they are composed of an infinite number of little particles, kept together by a force or power; but of what nature that power is, whether material or immaterial, we must remain ignorant till farther experiments are made. Some of the Newtonian philosophers, however, have positively determined these powers to be immaterial. In consequence of this supposition, they have so refined upon attractions and repulsions, that their systems seem not far from downright scepticism, or denying the existence of matter altogether. A system of this kind we find adopted by Dr Priestley *, from Messrs Boscovich and Michell, in order to solve some difficulties concerning the Newtonian doctrine of light. “ The easiest method (says he) of solving all difficulties, is to adopt the hypothesis of Mr Boscovich, who supposes that matter is not impenetrable, as has been perhaps universally taken for granted; but that it consists of physical points only, endued with powers of attraction and repulsion in the same manner as solid matter is generally supposed to be: provided there-

fore that any body move with a sufficient degree of velocity, or have a sufficient *momentum* to overcome any powers of repulsion that it may meet with, it will find no difficulty in making its way through any body whatever; for nothing else will penetrate one another but powers, such as we know do in fact exist in the flame place, and counterbalance or over-rule one another. The most obvious difficulty, and indeed almost the only one that attends this hypothesis, as it supposes the mutual penetrability of matter, arises from the idea of the nature of matter, and the difficulty we meet with in attempting to force two bodies into the same place. But it is demonstrable that the first obstruction arises from no actual contact of matter, but from mere powers of repulsion. This difficulty we can overcome; and having got within one sphere of repulsion, we fancy that we are now impeded by the solid matter itself. But the very fame is the opinion of the generality of mankind with respect to the first obstruction. Why, therefore, may not the next be only another sphere of repulsion, which may only require a greater force than we can apply to overcome it, without disordering the arrangement of the constituent particles; but which may be overcome by a body moving with the amazing velocity of light.

“ This scheme of the immateriality of matter, as it may be called, or rather the mutual penetration of matter, first occurred to Mr Michell on reading Baxter on the immateriality of the Soul. He found that this author's idea of matter was, that it consisted as it were of bricks cemented together with immaterial mortar. These bricks, if he would be consistent with his own reasoning, were again composed of less bricks, cemented likewise by an immaterial mortar; and so on *ad infinitum*. This putting Mr Michell upon the consideration of the several appearances of nature, he began to perceive that the bricks were so covered with this immaterial mortar, that if they had any existence at all, it could not possibly be perceived; every effect being produced, in nine instances of ten certainly, and probably in the tenth also, by this immaterial, spiritual, and penetrable mortar. Instead therefore of placing the world upon the giant, the giant upon the tortoise, and the tortoise upon he could not tell what, he placed the world at once upon itself.”

Other philosophers have supposed the powers both of gravitation and cohesion to be material; and to be only different actions of the ethereal fluid, or elementary fire. In support of this it hath been urged, that before we have recourse to a spiritual and immaterial power as the cause of any natural phenomenon, we ought to be well assured that there is no material substance with which we are acquainted, that is capable of producing such effects. In the present case, we are so far from having such assurance, that the contrary is manifest to our senses. One instance of this is in the experiment with the *Magdeburg hemispheres*, as they are called. These are two hollow hemispheres of brass, exactly fitted to one another, so as to form one globe when joined together, without admitting any air at the joining. In this state, if the air within them is exhausted by means of a pump, they will

Cohesion.

Bodies oppose each other not from actual contact.

Mr Baxter's opinion.

Cohesion supposed owing to elementary fire.

6
Existence of repulsive power proved.

8
Mr Michell's hypothesis adopted by Dr Priestley.

Cohesion.

cohere with such force, if they are five or six inches diameter, as to require a weight of some hundreds of pounds to separate them. The pressure of the atmosphere, we see, is in this case capable of producing a very strong cohesion; and if there is in nature any fluid more penetrating, as well as more powerful in its effects, than the air we breathe, it is possible that what is called the *attraction of cohesion* may some how or other be an effect of the action of that fluid. Such a fluid as this is the element of fire. Its activity is such as to penetrate all bodies whatever; and in the state in which it is commonly called *fire*, it acts according to the quantity of solid matter contained in the body. In this state, it is capable of dissolving the strongest cohesions observed in nature: but whatever is capable of dissolving any cohesion, must necessarily be endued with greater power than that by which the cohesion is caused. Fire, therefore, being able to dissolve cohesions, must also be capable of causing them, provided its power is exerted for that purpose. Nor will it seem at all strange that this fluid should act in two such opposite ways, when we consider the different appearances which it assumes. These are three, *viz.* fire, or heat, in which it consumes, destroys and dissolves; light, in which it seems deprived of all destructive or dissolvent power, and to be the most mild, quiet, and placid being in nature. The third state of this element is, when it becomes what is called the *electric fluid*; and then it attracts, repels, and moves bodies, in a vast variety of ways, without either burning or rendering them visible by its light. In this state it is not less powerful than in either of the other two; for a violent shock of electricity will displace and tear in pieces the most heavy and solid bodies. The seeming capricious nature of this fluid, however, probably renders it less suspected as the cause of cohesion, than it otherwise would be, were the attractions regular and permanent, which we observe it to occasion. But here we must observe, that the fluid has an existence in all bodies before the experiments are tried which make its effects visible to us, and was acting in them according to its settled and established laws. While acting in this manner it was perfectly invisible; and all we can do is, to produce some little infringement of these regular laws according to which it commonly acts. In some cases, however, the electrical attractions produced by art are found to be pretty permanent and strong. Thus, Mr Symmer, in some experiments with silk stockings, found their attraction so strong, that it required upwards of 15 pounds weight to separate them from each other; and this attraction would continue for more than an hour. In plates of glass, too, he observed a remarkable cohesion when electrified. In the Philosophical Transactions for 1777, we find this hypothesis taken notice of, and in some measure adopted, by Mr Henry. "Some gentlemen (says he) have supposed that the electric matter is the cause of the cohesion of the particles of bodies. If the electric matter be, as I suspect, a real elementary fire inherent in all bodies, that opinion may probably be well founded: and perhaps the folding of metals, and the cementation of iron, by fire, may be considered as strong proofs of the truth of their hypothesis."

Cohesion
Coiling.

On this last hypothesis we must observe, that if the electric, or any other fluid, is supposed to be the cause of the attraction of cohesion universally, the particles of that fluid must be destitute of all cohesion between themselves; otherwise we should be at as great a loss to account for the cohesion of these particles, as for that of terrestrial matter. Philosophers, indeed, do not suppose any cohesion between the particles of the electric fluid themselves; it is generally believed that the particles of this fluid are repulsive of one another, though attracted by all other matter. If this is a fact, we cannot suppose the electric fluid to be the cause of cohesion. The probability or improbability of the hypothesis just mentioned, must greatly depend on its being ascertained whether the particles of the electric fluid do really repel one another, and attract all other kinds of matter, or not; but for this we must refer to the article *ELECTRICITY*.

COHOBATION, in chemistry, an operation by which the same liquor is frequently distilled from the same body, either with an intention to dissolve this body, or to produce some change upon it. This is one of those operations which the ancient chemists practised with great patience and zeal, and which are now neglected. To make this operation easier, and to prevent the trouble of frequently changing the vessels, a particular kind of alembic, called a *pelican*, was invented. This vessel was made in the form of a cucurbit with an alembic-head, but had two spouts communicating with the body. As the vapour rose up into the head, it was gradually condensed, and ran down the spouts into the body of the pelican, from whence it was again distilled; and so on. This vessel is represented Plate LXXVII. fig. 6.

COHORN (N.) the greatest engineer Holland has produced. Among his other works, which are esteemed master-pieces of skill, he fortified Bergen-op-zoom; which, to the surprise of all Europe, was taken by the French in 1747. He wrote a treatise on fortification; and died in 1704.

COHORT, in Roman antiquity, the name of part of the Roman legion, comprehending about 600 men. There were ten cohorts in a legion, the first of which exceeded all the rest both in dignity and number of men. When the army was ranged in order of battle, the first cohort took up the right of the first line; the rest followed in their natural order: so that the third was in the centre of the first line of the legion, and the fifth on the left; the second between the first and third; and the fourth between the third and fifth: the five remaining cohorts formed a second line in their natural order.

COIF, the badge of a serjeant at law, who is called serjeant of the coif, from the lawn coif they wear under their caps, when they are created serjeants.

The chief use of the coif was to cover the clerical tonsure. See *TONSURE*.

COILING, on shipboard, implies a sort of serpentine winding of a cable or other rope, that it may occupy a small space in the ship. Each of the windings of this sort is called a *fak*; and one range of fakes upon the same line is called a *tier*. There are generally from five to seven fakes in a tier; and three or four tiers in the whole length of a cable. This, however,

however, depends on the extent of the fakes. The smaller ropes employed about the sails are coiled upon *cleats* at sea, to prevent their being entangled amongst one another in traversing, contracting, or extending the sails.

COLON, in the ancient Grecian theatres, the fame with the cavea of the Romans.

COMBRA, a handfome, large, and celebrated town of Portugal, capital of the province of Beira, with a bifhop's fee, and a famous univerfity. The cathedral and the fountains are very magnificent. It is feated in a very pleafant country abounding in vineyards, olive-trees, and fruits. It ftands on a mountain, by the fide of the river Mondego. W. Long. 8. 57. N. Lat. 40. 10.

COIN, a piece of metal converted into money by the impreffing of certain marks or figures thereon.

Coin differs from *MONEY* as the fpecies from the genus. *Money* is any matter, whether metal, wood, leather, glafs, horn, paper, fruits, fhells, or kernels, which have currency as a medium in *COMMERCE*. *Coin* is a particular fpecies, always made of metal, and ftruck according to a certain procefs called *COINING*.

The precise epocha of the invention of money is too ancient for our annals; and, if we might argue from the neceffity and obviousnefs of the thing, muft be nearly coeval with the world.

Whether *coins* be of equal antiquity, may admit of fome doubt; efpecially as moft of the ancient writers are fo frequent and exprefs in their mention of leathern-moneys, paper-moneys, wooden-moneys, &c. Some, however, notwithstanding this, are of opinion, that the firft moneys were of metal: the reafons they give, are the firmnefs, neatnefs, cleanlinefs, durability, and univerfality of metals; which, however, do rather conclude they ought to have been fo, than that they actually were fo.

In effect, the very commodities themfelves were the firft moneys, *i. e.* were current for one another by way of exchange; and it was the difficulty of cutting or dividing certain commodities, and the impoffibility of doing it without great lofs, that firft put men on the expedient of a general medium. See *EXCHANGE*.

Indeed, thus much may be faid in behalf of *coins*, that, on this view, it was natural for men to have their firft recourfe to metals; as being almoft the only things whole goodnefs, and as it were integrity, is not diminiſhed by partition; befides the advantages above expreffed, and the conveniencies of melting and returning them into a maſs of any fize or weight.

It was probably, then, this property of metals which firft accuſtomed people, who trafficked together, to account them in lieu of quantities of other merchandizes in their exchanges, and at length to ſubſtitute them wholly in their ſtead; and thus aroſe money: as it was their other property to preferve any mark or impreſſion a long time, which confirmed them in the right; and thus was the firſt riſe of *coins*. See *METAL*.

In the firſt ages, each perſon cut his metal into pieces of different fizes and forms, according to the quantity to be given for any merchandize, or according to the demand of the ſeller, or the quantity ſtipu-

lated between them. To this end they went to market laden with metal in proportion to the purchaſe to be made, and furniſhed with inſtruments for portioning it, and ſcales for dealing it out, according as occaſion required. By degrees, it was found more commodious to have pieces ready weighed; and as there were different weights required according to the value of the different wares, all thoſe of the ſame weight began to be diſtinguiſhed with the ſame mark or figure: thus were coins carried one ſtep further. At length the growing commerce of money beginning to be diſturbed with frauds, both in the weights and the matter, the public authority interpoſed; and hence the firſt ſtamps or impreſſions of money; to which ſucceeded the names of the monies; and at length the effigy of the prince, the date, legend, and other precautions to prevent the alterations of the ſpecies; and thus were coins completed.

Modern COINS. In England the current ſpecies of gold are the guinea, half-guinea, Jacobus, laureat, angel, and roſe-noble: the four laſt of which are now ſeldom to be met with; having been moſt of them converted into guineas, chiefly during the reign of Charles II. and James II. The ſilver coins are the crown, half-crown, ſhilling, and fixpence. Copper coins are the half-penny and farthing.

In Scotland, by the articles of the Union, it is appointed that all the coins be reduced to the Engliſh, and the ſame accounts obſerved throughout. Till then the Scots had their pounds, ſhillings, and pence, as in England; but their pound was but 20 pence Engliſh, and the others in proportion: accordingly, their merk was 13½ s. Scots, current in England at 13½ d. their noble in proportion. Beſides theſe they had their turner-pence and half-pence; their penny ⅔ of that of England: beſides baſe money of achiſons, babees, and placks. The bodle ⅓ of the penny, ⅓ of the achiſon, ⅓ of the babee, and ⅓ of the plack.

In Ireland, the coins are as in England, *viz.* ſhillings, pence, &c. with this difference, that their ſhilling or harper is but equal to nine pence ſterling; whence their pound is only ⅔ of ours, or 15 s.

But, for a view of all the coins preſently current in the four quarters of the globe, with their values and proportions, ſee the *Table* ſubjoined to the article *MONEY*.

In many places ſhells are current for coins; particularly a ſmall white kind dug out of the ground in the Maldives, and ſome parts of America, called in the Indies *cowries*, or *coris*, on the coaſt of Africa *bonges*, and in America *porcelaines*; of which it takes a vaſt number to be equivalent in value to a penny. Of zimbis, another kind of ſhell current, particularly in the kingdoms of Angola and Congo, two thouſand make what the negroes call a *macoute*; which is no real money; for of this there is none in that part of Africa but a manner of reckoning: thus, two Flemiſh knives they eſteem a macoute; a copper-baſon two pounds weight, and 12 inches diameter, they reckon three macoutes; a ſulce 10, &c.

In ſome places fruits are current for coins. Of theſe there are three forts uſed; two in America, particularly among the Mexicans, which are the cacao and maize: the other in the Eaſt Indies, *viz.* almonds, brought

Coin.

brought thither from Lar, and growing in the deserts of Arabia. Of cacao is esteemed equivalent to a Spanish rial, or seven pence sterling. Maize has ceased to be a common money since the discovery of America by the Europeans. Almonds are chiefly used where the *cowries* are not current. As the year proves more or less favourable to this fruit, the value of the money is higher or lower. In a common year 40 almonds are set against a *peſcha*, or half-penny sterling; which brings each almond to $\frac{1}{40}$ of a farthing.

Ancient Coins are those chiefly which have been current among the Jews, Greeks, and Romans. Their values and proportions are as follows.

40 20 10 5 2	Denarius	—	0 : 7 : 3

Notes. Of these the denarius, victoriatius, sestertius, and some times the as, were of silver, the rest of brass. See As, &c.

There were sometimes also coined of brass the triens, sextans, uncia, sextula, and dupondius.

The Roman gold coin was the aureus, which weighed generally double the denarius; the value of which, according to the first proportion of coinage, mentioned by Pliny, was

According to the proportion that obtains now amongst us, worth

According to the decuple proportion, mentioned by Livy and Julius Pollux, worth

According to the proportion mentioned by Tacitus, and which afterwards obtained, whereby the aureus exchanged for 25 denarii, its value

COIN, in architecture, a kind of dye cut diagonal-wise, after the manner of a flight of a stair-case, serving at bottom to support columns in a level, and at top to correct the inclination of an entablature supporting a vault.

COIN is also used for a solid angle composed of two surfaces inclined towards each other, whether that angle be exterior, as the coin of a wall, a tree, &c. or interior, as the coin of a chamber or chimney. See QUOIN.

COINAGE, or COINING, the art of making money, as performed either by the hammer or mill.

Formerly the fabric of coins was different from what it is at present. They cut a large plate of metal into several little squares, the corners of which were cut off with sheers. After having shaped these pieces, so as to render them perfectly conformable, in point of weight, to the standard piece, they took each piece in hand again, to make it exactly round, by a gentle hammering. This was called a planchet, and was fit for immediate coining. Then engravers prepared, as they still do, a couple of steel mallets in form of dyes, cut and terminated by a flat surface, rounded off at the edges. They engraved or stamped on it the hollow of a head, a cross, a scutcheon, or any other figure, according to the custom of the times, with a short legend. As one of these dyes was to remain dormant, and the other moveable, the former ended in a square prism, that it might be introduced into the square hole of the block, which, being fixed very fast,

kept

CHRONOMETERS

Fig. 12. CROW FOOT.

ANCIENT CROWNS

A Bell's scalp!

kept the dye as steady as any vice could have done. The planchet of metal was horizontally laid upon this inferior mafs, to receive the ftamp of it on one fide, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved furface refting upon the planchet, had at its oppofite extremity a flat fquare, and larger furface, upon which they gave feveral heavy blows, with a hammer of an enormous fize, till the double ftamp was fufficiently, in relievo, impreffed on each fide of the planchet. This being finifhed, was immediately fucceeded by another, and they thus became a ftandard coin, which had the degree of finenefs the weight and mark determined by the judgment of the infpectors, to make it good current money. The ftiong tempering which was and is ftill given to the two dyes, rendered them capable of bearing thofe repeated blows. Coining has been confiderably improved and rendered expeditious, by feveral ingenious machines, and by a wife application of the beft physical experiments to the methods of fining, dyeing, and ftamping the different metals.

The three fineft inftruments the mint-man ufes, are the laminating engine; the machine for making the impreffions on the edges of coins; and the mill.

After they have taken the laminæ, or plates of metal, out of the mould into which they are caft, they do not beat them on the anvil, as was formerly done, but they make them pafs and repafs between the feveral rollers of the laminating engine, which being gradually brought clofer and clofer to each other, preftently give the laminæ its uniform and exact thicknefs. Inftead of dividing the laminæ into fmall fquares, they at once cut clean out of it as many planchets as it can contain, by means of a fharp fteel trepan, of a roundifh figure, hollow within, and of a proportionable diameter, to fhape and cut off the piece at one and the fame time. After thefe planchets have been prepared and weighed with ftandard pieces, filed or fcraped to get off the fuperfluous part of the metal, and then boiled and made clean, they arrive, at laft, at the machine, (fig. 1.), which marks them upon the edge; and finally, the mill, (fig. 2.) which fqueezing each of them fingly between the two dyes, brought near each other with one blow, forces the two furfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which ferves to laminate lead, gives a fufficient notion of that which ferves to flatten gold and filver laminæ between rollers of a leffer fize. See LAMINATING.

The principal pieces of the machine, (fig. 1.), to ftamp coins on the edge, are two fteel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thicknefs of one of the laminæ, and the other half on the thicknefs of the other; and thefe two laminæ are ftaight, although the planchet marked with them be circular.

When they ftamp a planchet, they firft put it between the laminæ in fuch a manner, as that thefe being each of them laid flat upon a copper-plate, which is fattened upon a very thick wooden table, and the planchet being likewife laid flat upon the fame plate, the edge of the planchet may touch the two laminæ on each fide, and in their thick part.

One of thefe laminæ is immovable, and fattened with feveral fcrews; the other fides by means of a dented wheel, which takes into the teeth that are on the furface of the laminæ. This fiding laminæ makes the planchet turn in fuch a manner, that it remains ftamped on the edge, when it has made one turn. Only crown and half-crown pieces can bear the impreffion of letters on the thicknefs of their edges.

The coining engine or mill is fo handy, (fig. 2.), that a fingle man may ftamp twenty thoufand planchets in one day: gold, filver, and copper planchets, are all of them coined with a mill, to which the coining fquares, (fig. 3.) commonly called dyes, are fattened; that of the face under, in a fquare box garnifhed with male and female fcrews, to fix and keep it ftady; and the other above, in a little box garnifhed with the fame fcrews, to fatten the coining fquare. The planchet is laid flat on the fquare of the effigy, which is dormant; and they immediately pull the bar of the mill by its cords, which caufes the fcrew fet within it to turn. This enters into the female fcrew, which is in the body of the mill, and turns with fo much ftrength, that by pulling the upper fquare upon that of the effigy, the planchet, violently preffed between both fquares, receives the impreffion of both at one pull, and in the twinkling of an eye.

The planchet thus ftamped and coined, goes through a final examination of the mint wardens, from whole hands it goes into the world.

In the COINING of Medals, the procefs is the fame, in effect, with that of money; the principal difference confifting in this, that money having but a fmall relievo, receives its impreffion at a fingle ftroke of the engine; whereas for medals, the height of their relievo makes it neceffary that the ftroke be repeated feveral times: to this end the piece is taken out from between the dyes, heated, and returned again; which procefs in medallions and large medals, is repeated fifteen or twenty times before the full impreffion be given, care muft be taken, every time the planchet is removed, to take off the fuperfluous metal ftretched beyond the circumference with a file. Medallions, and medals of a high relievo, are ufually firft caft in fand, by reafon of the difficulty of ftamping them in the prels, where they are put only to perfect them; in regard the fand does not leave them clear, fmooth, and accurate enough. Therefore we may fee that medals receive their form and impreffion by degrees, whereas money receives them all at once.

BRITISH COINAGE, both by the beauty of the engraving, and by the invention of the impreffions on the edges, that admirable expedient for preventing the alteration of the fpecies, is carried to the utmoft perfection.

It was only in the reign of king William III. that the hammer-money ceafed to be current in England, where till then it was ftuck in that manner, as in other nations. Before the hammer fpecies was called in, the Englifh money was in a wretched condition, having been filed and clipped by natives as well as foreigners, infomuch that it was fcarce left of half the value: the retrieving this diftreffed ftate of the Englifh money is looked upon as one of the glories of king William's reign.

The

The British coinage is now wholly performed in the Tower of London, where there is a corporation for it, under the title of the mint. Formerly there were here, as there are still in other countries, the rights of seignorage and brassage: but since the eighteenth year of king Charles the Second, there is nothing taken either for the king, or for the expences of coining; so that weight is returned for weight, to any person who carries their gold and silver to the Tower.

The species coined in Great Britain are esteemed contraband goods, and not to be exported. All foreign species are allowed to be sent out of the realm, as well as gold and silver in bars, ingots, dust, &c.

Barbary COINAGE, particularly that of Fez and Tunis is under no proper regulations, as every goldsmith, Jew, or even private person, undertakes it at pleasure; which practice renders their money exceedingly bad, and their commerce very unsafe.

Muscovite COINAGE. In Muscovy there is no other coin struck but silver, and that only in the cities of Moscow, Novogrod, Twere, and Pleskow, to which may be added Peterburgh. The coinage of each of these cities is let out to farm, and makes part of the royal revenue.

Persian COINAGE. All the money made in Persia is struck with a hammer, as is that of the rest of Asia: and the same may be understood of America, and the coasts of Africa, and even Muscovy: the king's duty, in Persia, is seven and a half *per cent.* for all the moneys coined, which are lately reduced to silver and copper, there being no gold coin there, except a kind of medals, at the accession of a new sopher.

Spanish COINAGE is esteemed one of the least perfect in Europe. It is settled at Seville and Segovia, the only cities where gold and silver are struck.

COIRE, or, as the Germans call it, *CHUR*, a large and handsome town of Switzerland, and capital of the country of the Grisons, with a bishop's see whose prelate has the right of coining money. It is divided into two parts; the least of which is of the Roman Catholic religion, and the greatest of the Protestant. It is governed by its own laws, and seated in a plain, abounding in vineyards and game, on the river Pfersure, half a mile from the Rhine. E. Long. 9. 27. N. Lat. 46. 50.

COITION, the intercourse between male and female in the act of generation. See *GENERATION*, and *CONGRESS*.

It is observed that frogs are forty days in the act of *coition*. Bartholine, &c. relate, that butterflies make 130 vibrations of the wings in one act of *coition*.

COIX, *JON'S TEARS*; a genus of the triandria order, belonging to the monœcia class of plants. Of this there is but one species, a native of the Archipelago islands, and frequently cultivated in Spain and Portugal, and also in the West Indies. It is an annual plant, rising from a fibrous root, with two or three jointed stalks, to the height of two feet, with single, long, narrow leaves at each joint, resembling those of the reed; at the base of the leaves come out the spikes of flowers standing on short foot-stalks; the seeds greatly resemble those of Gromwell; whence the plant has by some writers been called *Lithospermum*. This plant may be propagated in this country by seeds

brought from Portugal, and sown on a hot-bed; after which the young plants are to be removed into a warm border, and planted at the distance of two feet at least from each other. They will require no other care than to be kept free from weeds. In Spain and Portugal the poor people grind the seeds of this plant, in times of scarcity, and make a coarse kind of bread of them. The seeds are inclosed in small capules about the bigness of an English pea, and of different colours. These are strung upon silk, and used instead of bracelets by some of the poorer sort in the West Indies, but especially by the negroes.

COKE, or *COOKE* (Sir Edward), lord chief justice of the king's bench in the reign of James I. was descended from an ancient family in Norfolk, and born at Milham in 1549. When he was a student in the Inner-Temple, the first occasion of his distinguishing himself was his stating the case of a cook belonging to the Temple so exactly, that all the house, who were puzzled with it, admired him and his pleading, and the whole bench took notice of him. After his marriage with a lady of a great fortune, preferments flowed in upon him. The cities of Norwich and Coventry chose him for their recorder; the county of Norfolk, for one of their knights in parliament; and the house of commons, for their speaker, in the 35th year of queen Elizabeth. The queen appointed him solicitor-general in 1592, and attorney-general the next year. In 1603, he was knighted by king James I.; and in November the same year, upon the trial of Sir Walter Raleigh, &c. at Winchester, he treated that gentleman with a scurrility of language hardly to be paralleled. June 27, he was appointed lord chief justice of the common pleas; and in 1613, lord chief justice of the king's bench, and sworn one of the privy council. In 1615, he was very vigorous in the discovery and prosecution of the persons employed in poisoning Sir Thomas Overbury in the Tower in 1612. His contest not long after with the lord chancellor Egerton, with some other cases, hastened the ruin of his interest at court: so that he was sequestered from the council-table and the office of lord chief justice. In 1621, he vigorously maintained in the house of commons, that no proclamation is of any force against the parliament. The same year, being looked upon as one of the great incendiaries in the house of commons, he was removed from the council of state with disgrace; the king saying, that "he was the fittest instrument for a tyrant that ever was in England;" he was also committed to the Tower, and his papers were seized. Upon the calling of a new parliament in 1625, the court-party, to prevent his being elected a member, got him appointed sheriff of Buckinghamshire; to avoid the office, if possible, he drew up exceptions against the oath of a sheriff, but was obliged to undertake the office. In 1628, he spoke vigorously upon grievances; and made a speech in which he affirmed, that "the duke of Buckingham was the cause of all our miseries." While he lay upon his death-bed, his papers and last will were seized by an order of council. He died in 1634, and published many works: the most remarkable are his Institutes of the laws of England; the first part of which is only a translation and comment of Sir Thomas Littleton, one of the

Cold.

the chief justices of the common pleas in the reign of Edward IV.

COKENHAUSEN, a strong town of Livonia in Sweden, on the river Divina. E. Long. 24. 56. N. Lat. 56. 40.

COL, a name given by some to one of the western islands of Scotland; it abounds in corn, pasture, salmon, eels, and cod. W. Long. 7. 35. N. Lat. 57. 8.

COLBERG, a strong, handsome sea-port town of Germany, in Pomerania, belonging to the king of Prussia. It is remarkable for its salt-works; and is seated at the mouth of the river Perant, on the Baltic-sea, 60 miles north-east of Stetin, and 30 north-east of Camin. E. Long. 15. 57. N. Lat. 54. 18.

COLBERT (John Baptiste), marquis of Signelai, reputed the greatest statesman France ever produced. He was prime minister to Lewis XIV. and was equally renowned in every department of his extensive administration. The polite arts, commerce, and manufactures, stood indebted to him for some signal advantage every year of his ministry. His attention to the marine service was no less conspicuous; for he built arsenals at Marseilles, Toulon, Brest and Rochfort, which he kept well provided with naval and military stores. The regulations he effected in the courts of judicature, and in the finances, completed his character, and rendered it much more renowned than that of Sully, because his views were more extensive. He died in 1683, aged 64. The house of Colbert has produced several eminent men in the church, the army, and the cabinet of France.

COLCHESTER, the capital of the county of Essex in England. It is by some thought to be the place mentioned by Antoninus under the name of *Colonia*, different from Colonia Camaloduni, and by the Saxons called *Cæsar Colin*. It is a beautiful, populous, and pleasant town, extended on the brow of a hill from east to west, and adorned with 10 churches. It had formerly strong walls and a castle, but now there are scarce any remains of either. This place is said to have given birth to Fl. Julia Helena, mother to Constantine the Great, and daughter to king Coelus, so much celebrated for her piety and zeal in propagating the Christian religion. Here, and in the neighbouring towns, is a great manufacture of hays and fays. It is also famous for its oysters; in pickling and barrelling which, the inhabitants excel. The rendering navigable the river Coln, on which the town stands, has greatly promoted its trade and manufactures. The town had formerly an abbey whose abbot was mitred and sat in parliament. In the time of the civil wars it was besieged by the parliament's troops and reduced by famine. It was formerly a corporation, but lately lost its charter for some misdemeanor; however, it still sends two members to parliament. E. Long. 1. 2. N. Lat. 51. 55.

COLCHICUM, MEADOW-SAFFRON; a genus of the trigynia order, belonging to the hexandria class of plants. There are three species, all of them bulbous-rooted, low, perennials, possessing the singular property of their leaves appearing at one time, and their flowers at another; the former rising long and narrow from the root in the spring, and decaying in June; the flowers, which are inopetalous, long, tubular,

erect, and six-parted, rise naked from the root in autumn, not more than four or five inches high. Their colours afford a beautiful variety; being purple, variegated purple, white, red, rose-coloured, yellow, &c. with single and double flowers. They are all hardy plants, inasmuch that they will flower though the roots happen to lie out of the ground; but by this they are much weakened. They are propagated by offsets from the roots of which they are very prolific. These are to be taken up and divided at the decay of the leaf in summer, planting the whole again before the middle of August. They are to be placed at nine inches distance from one another, and three inches deep in the ground.

The root of this plant is poisonous. When young and full of sap, its taste is very acid; but when old, mealy and faint. Two drachms of it killed a large dog in 13 hours, operating violently by stool, vomit, and urine. One grain of it swallowed by a healthy man, produced heats in the stomach, and soon after flushing heats in different parts of the body, with frequent shiverings, followed by colicky pains; after which an itching in the loins and urinary passages was perceived; then came on a continual inclination to make water, a tenesmus, pain in the head, quick pulse, thirst, and other disagreeable symptoms. Notwithstanding these effects, however, an infusion of the roots in vinegar, formed into a syrup with honey or sugar, proves a safe and powerful pectoral and diuretic, and is often of service in dropsies, &c. The virtues of colchicum seem much to resemble those of squills.

COLCOTHAR, the substance remaining after the distillation or calcination of martial vitriol by a violent fire. See **CHEMISTRY**, n° 112.

COLD, in a relative sense, generally signifies that sensation which accompanies the transition of the fine vessels of the human body from an expanded to a more contracted state. In an absolute sense, it means the agent by which that sensation is produced.

Concerning the cause of this sensation, which alone can be properly called *cold* in the abstract, philosophers are by no means agreed; some maintaining, that the term is merely relative, and owing only to the different degrees of *heat* contained in different bodies; others, that *cold* is as really and truly a substance as heat itself. The arguments on both sides may be stated as follows:

1. The sensation of cold may be produced without abstracting from the human body any part of its sensible heat; nay, from some observations made by the thermometer, it appears, that a violent degree of cold may be felt when the body is really *hotter* than usual. Examples of this occur in the cold fits of intermittents, and the chinefs which usually precedes fevers of all kinds.

2. The body may be so disposed, that the same substance may feel hot and cold to different parts of it. Thus, suppose a person has one hand cooled so as to sink Fahrenheit's thermometer to 60°, while the other raises it to 90; if both of them are now plunged into a vessel of water reduced to the temperature of 75°, this water will feel hot to one hand and cold to the other.

3. Though we see a visible spring and fountain of

Cold. heat, viz. the sun, who by his light diffuses warmth to the whole world, yet we perceive no such spring or origin of cold. The sun's preference always brings warmth; and of this warmth there is a very evident cause, viz. the light which is continually flowing from him: his absence is as certainly attended with cold; but for this cold we observe no positive cause. We see, that to produce the most intense cold nothing else than the mere privation of the sun's light is requisite. As therefore we have already seen that it is possible to produce different sensations of heat and cold, without varying the temperature of the substance by which they are produced, it seems most probable, that these sensations are the result of a mere negation, or want of that heat to which our bodies have been accustomed, or which is necessary to their subsistence.

In answer to the above, it hath been urged,

3
Answered. 1. The two first instances prove nothing. From them it only appears, that cold produces a contraction of the fine vessels of our bodies; and that, by whatever cause this contraction is produced, the same sensation always follows it: but whether this sensation is produced in all cases by a negative or a positive, can by no means be determined by such experiments.

2. The third argument proves by far too much: for if the mere absence of the sun's light and heat was sufficient to produce cold, then caves and other places that are never exposed to the sun, ought to be cold beyond all imagination. The contrary, however, is manifest to daily experience. At a certain depth below ground, an uniform temperature is observed, which scarce ever varies, provided a circulation of air is presented as much as possible. In some caverns indeed, such as those in Mount Atna, where the air circulates freely, the cold is very intense*.

* See *Ætius*.
4
Atmosphere, the source of cold. It would seem therefore, that as the sun is the origin and fountain of heat, so is our atmosphere the source from whence cold is derived; and that this atmosphere, or something in it, is as really and positively cold, as the light of the sun is really and positively heat. This will become the more probable when we consider, that the beams of the sun are not capable, as emitted from him, of heating the atmosphere. They must first be detained in it by reflection from the earth; and where this reflection cannot reach, as on the tops of very high mountains, an intense degree of cold is always found to take place. Again, even in those places where the cold is most intense, it is found only to affect the surface of the ground. This shews, that the cause of cold lies in the atmosphere, and not in the absence of the sun's light; otherwise, in those regions, however cold the surface was, the under parts of the soil must be much colder. We see, therefore, that there is in nature a positive source of cold as well as of heat; the atmosphere being the source of the one, as the sun is of the other: and these two always acting opposite to one another, contribute to preserve that exact balance which is necessary for the existence of the system of nature in the form we see it; and, were the one or the other finally to get the better, the whole world, or at least its inhabitants, must perish in a miserable manner.

It will scarce be denied, that, were the sun to cease the emission of his light for a few months, the most

intense and violent cold would by that time have taken place in the atmosphere. But, what has become of the immense quantity of heat and light emitted from the sun since the creation of the world? It is absorbed by terrestrial bodies, we know; but what becomes of it afterwards? The atmosphere perhaps takes it from terrestrial bodies: nay, indeed, there is here not the least doubt; for we know that exposure to the air is a very ready way to cool any thing. Still, however, the difficulty is not solved: for it is most certain, that, since the world was created, the earth and its atmosphere have received as much heat from the sun as would have been sufficient to have set them on fire a thousand times over; and seeing this hath not been done, we must necessarily conclude, either that heat, after some time, ceases to be heat, or that there is in nature a power able to countermand or suspend its effects; and that this power, though invisible as heat itself is, must be really and truly a positive substance, and is that which we commonly call cold.

The first of these positions, viz. that heat, after some time, ceases to be heat, is contrary to all experience. It is certain, that no body whatever loses its heat but by communicating it to others. Were there not, therefore, an opposite principle in nature, the quantity of heat accumulated in terrestrial bodies must have been continually increasing; and, as already observed, would long since have destroyed the whole world. By supposing, however, a cold principle as well as a hot one, the difficulty entirely vanishes. On this supposition it is impossible that a quantity of heat can enter any substance without expelling an equal quantity of cold from it. When the cause producing the heat is removed, the cold then re-enters and displaces the heat, and so on.

5
3. That cold is a positive principle is not a mere hypothesis, but may be ascertained by experiment. From what we have just now said it follows, that if a body is heated, the cold ought to fly from it, and, attacking those substances in the vicinity of the heated body, make them colder than before. To this purpose we have an experiment recorded in the philosophical Transactions, n^o 274, p. 951. It was made by M. Geoffroy. "I put (says he) some cold water into a great basin. I put into the middle of the water a cucurbit of glass full of water equally cold. I put into the cucurbit a very good thermometer, which I let lie a good while for a trial. When it was adjusted to a degree proportionable to the cold of the water, I threw suddenly into the water in the basin four or five shovels full of coals well lighted; and in an instant the liquor of the thermometer descended two or three lines. After some moments the liquor rose again, when the heat in the water of the basin was communicated to the glass."

These are the principal arguments that have been urged *pro* and *con* in this question. The last mentioned experiment, if it can be depended on, seems to be decisive in favours of those who assert cold to be a positive substance. But however philosophers may decide this question, we believe the generality of mankind will always take it for granted that cold is a substance as well as heat.

Among those who allow cold to be a substance, there

Cold.

Experiment, proving cold to be a positive substance.

Cold. 6 Con- jec- tures con- cerning the substance of cold.	there is no small disagreement about what sort of substance it is. Some have supposed it to consist in certain nitrous or saline particles diffused through the atmosphere; others attribute cold to the action of the electric fluid. The first hypothesis is evidently false; for if such saline particles existed, it is impossible but they must on some occasions discover themselves, which they are never known to do. Concerning the latter, no experiments either have been or probably can be made; because every experiment in electricity we can make is only throwing the fluid into some kind of motion, in which case it would be more apt to produce heat than cold. It is observable, however, that the radiell conductors of the electric fluid are likewise the best conductors of heat and cold; and <i>vice versa</i> . Thus, metals, which are the best conductors of electricity, also transmit heat or cold very readily through them: whereas wool, hair, silk, &c. which will not conduct this fluid, are found to be the best preservatives against excesses of heat or cold. See ELECTRICITY.	fions of spirit of salt on pounded ice sunk it 14 th below 0; but by repeated affusions of spirit of nitre, Mr Fahrenheit sunk it to 40 th below 0; and the spirit of nitre itself though very strong was then frozen. Even these excessive degrees of cold are naturally produced by the atmosphere in some parts of the world. In 1708 Mr Derham acquaints us that his thermometer was within one tenth of an inch of its station when plunged into a mixture of snow and salt. In 1732, the thermometer at Peterburgh stood at 28 th below 0. In 1737, when the French academicians wintered at the north polar circle or near it, the thermometer sunk 33 th below 0. The spirit of wine with which some of their thermometers were filled was then frozen; the air, when suddenly admitted into their warm rooms, became intolerable to their bodies, their breasts seemed to be rent when they breathed it, and the moisture of the air was immediately converted into whirls of snow. In this degree of cold every metallic substance, when touched, blistered the skin like red-hot iron. This, however, is but trifling in comparison of what hath been observed at a place in Siberia, lying in Lat. 58. 10. where the thermometer fell to 118 th below 0; nay, by some late accounts from that country, we are informed, that the cold hath been observed there of such a strength as to freeze the quicksilver in the thermometers. When Mr Brown first made this famous experiment of freezing quicksilver, the thermometer at Petersburg stood at 40 th below 0. By repeated affusions of spirit of nitre on snow, he made it sink 108 degrees lower; after which the cold became immeasurable, because the quicksilver was frozen. But for a particular account of this experiment, see the article CONGELATION. Very great degrees of cold also may be produced by evaporation; for a particular account and explanation of which, see the article EVAPORATION.	Cold Coldinguen 8 Excessive degrees of natural cold.
7 Cold pro- duced arti- ficially by means of salts.	Most kinds of saline substances mixed with water make the mixture considerably colder than either the salt or the water was before. In the paper quoted above, Mr Geoffroy gives an account of several experiments with regard to this power of the salts to produce cold. Four ounces of sal ammoniac, mixed with a pint of common water, made his thermometer descend two inches and nine lines below the temperature of the water, in less than a quarter of an hour. An ounce of the same salt, put into four or five ounces of distilled vinegar, made the liquor descend two inches and three lines. Half an ounce of sal ammoniac, mixed with three ounces of spirit of nitre, made the thermometer descend two inches and five lines; but on using spirit of vitriol instead of that of nitre, it sunk three inches and six lines; and what is very remarkable, though this mixture was so extremely cold, the vapours raised by it had a considerable degree of heat. Four ounces of saltpetre mixed with a pint of water, sunk the thermometer one inch three lines; but a like quantity of sea-salt sunk it only two lines. With acids, even with its own spirit, sea-salt produced a considerable heat. Volatile alkaline salts produced cold in proportion to their purity; but fixed alkalies, heat. The greatest degree of cold, however, as yet produced by mixtures of this kind, was shewn by Mr Homburg; and the experiment may be performed as follows. "Take a pound of corrosive sublimate, and as much sal ammoniac; powder them separately, and mix both the powders very exactly; put the mixture into a vial, pouring upon it a pint and a half of distilled vinegar, and shake all well together. This composition grows so cold that a man can scarce hold it in his hands in summer. And it happened, as Mr Homburg was making the experiment, that the subject froze." This also once happened to M. Geoffroy with common water and sal ammoniac; but he says he never could make the experiment succeed again.	COLD, in medicine. See (the <i>Index</i> subjoined to) MEDICINE.	COLD, in farriery. See there, § iii. COLDENIA, a genus of the tetragynia order, belonging to the tetrandria class of plants. There is but one species, a native of India. It is an annual plant, whose branches trail on the ground, extending about six inches from the root. They are adorned with small blue flowers growing in clusters, which come out from the wings of the leaves. They are propagated by seeds sown on a hot-bed; when the plants come up, they may be removed each into a separate pot, and plunged into a hot-bed of tanner's bark, where they are to remain constantly.
	If instead of making these experiments with water in its fluid state, we take it when converted into ice or rather snow, incredible degrees of cold may be produced. A mixture of snow and common salt sinks Fahrenheit's thermometer to 0. If pot-ashes are mixed with powdered ice, it sinks 8 th farther. Two affu-	COLDINGHAM, a barren heathy moor on the borders of Scotland. It is only remarkable for a convent formerly filled with most heroic nuns; who, to preserve themselves inviolate from the Danes, cut off their lips and noses; and thus rendering themselves objects of horror, were, with their abbess Ebba, in 870, burnt in the monastery by the disappointed savages.	COLDINGUEN, a town of Denmark, in North Jutland, and diocese of Ripen. It is remarkable for its bridge, over which pass all the oxen and other cattle that go from Jutland into Germany, which brings in a considerable revenue to the king. It is seated on

an eminence, in a pleasant country abounding with game. E. Long. 9. 25. N. Lat. 55. 35.

COLD-FINCH, a species of MOTACILLA.

COLD-SHIRE IRON, that which is brittle when cold.

COLE (William), the most famous botanist of his time, was born at Adderbury in Oxfordshire, about the year 1626, and studied at Merton college in Oxford. He at length removed to Putney, near London; and published "The Art of Simpling; and Adam in Eden, or Nature's Paradise." Upon the restoration of king Charles II. he was made secretary to Dr Duppa, bishop of Winchester; but died two years after, aged 37.

COLE-FISH, a species of GADUS.

COLE-Seed, the seed of the *napus sativa*, or long-rooted, narrow-leaved rapa, called in English *navew*, and reckoned by Linnaeus among the brassicas, or cabbage-kind. See BRASSICA.

This plant is cultivated to great advantage in many parts of England, on account of the rape oil expressed from its seeds. The practice of sowing it was first introduced by those Germans and Dutchmen who drained the fens of Lincolnshire; and hence the notion hath generally prevailed, that it will thrive only in a marshy soil, but this is now found to be a mistake. In preparing the land which is to receive it, care must be taken to plow it in May, and again about midsummer, making the ground as fine and even as possible. It is to be sown the very day of the last plowing, about a gallon on an acre. In the months of January, February, and March, it affords very good food for cattle, and will sprout again when cut; after which it is excellent nourishment for sheep. After all, if it is not too closely fed, it will bear seed against next July. The same caution, however, is requisite with this food as with clover, till cattle are accustomed to it, otherwise it is apt to swell them. When this plant is cultivated solely with a view to the seed, it must be sown on deep strong land without dung, and must be suffered to stand till one half of the seeds at least are turned brown; which, according to the seasons, will be sometimes sooner sometimes later. In this state it is to be cut in the same manner and with the same care as wheat; and every handful as it is cut is to be regularly ranged on sheets, that it may dry leisurely in the sun, which will commonly be in a fortnight; after which it is to be carefully threshed out, and carried to the mill for expressing the oil. The produce of cole-feed is generally from five to eight quarters on an acre; and is commonly sold at 20s. per quarter.

COLEOPTERA, or BEETLE, the name of Linnaeus's first order of insects. See ZOOLOGY.

COLEWORT. See BRASSICA.

COLERAIN, a large town of Ireland, in the county of Londonderry and province of Ulster; seated on the river Bann, in W. Long. 7. 2. N. Lat. 55. 10.

COLES (Elitha), author of the well known Latin and English dictionary, was born in Northamptonshire about the year 1640; and was entered of Magdalene College Oxford, which he left without taking a degree; and taught Latin to young people, and English to foreigners, in London, about the year 1663. He

afterwards became an usher in Merchant-taylor's school; but for some great fault, nowhere expressly mentioned, he was forced to withdraw to Ireland, from whence he never returned. He was, however, a good critic in the English and Latin tongues; and wrote several useful books of instruction in his profession.

COLET (John), dean of St Paul's, the son of Henry Colet knight, was born in London in the year 1466. His education began in St Anthony's school in that city; from whence, in 1483, he was sent to Oxford, and probably to Magdalene college. After 7 years study of logic and philosophy, he took his degrees in arts. About the year 1493, Mr Colet went to Paris, and thence to Italy, probably with a design to improve himself in the Greek and Latin languages, which at this time were imperfectly taught in our universities. On his return to England in 1497, he took orders; and returned to Oxford, where he read lectures gratis, on the epistles of St Paul. At this time he possessed the rectory of Dennington in Suffolk, to which he had been instituted at the age of 19. He was also prebendary of York, and canon of St Martin's le Grand in London. In 1502, he became prebendary of Sarum; prebendary of St Paul's, in 1505; and immediately after, dean of that cathedral, having previously taken the degree of doctor of divinity. He was no sooner raised to this dignity, than he introduced the practice of preaching and expounding the Scriptures; and soon after established a perpetual divinity lecture in St Paul's church, three days in every week; an institution which gradually made way for the reformation. About the year 1508, dean Colet formed his plan for the foundation of St Paul's school, which he completed in 1512, and endowed with estates to the amount of 122 l. and upwards. The celebrated grammarian, William Lilye, was his first master, and the company of mercers were appointed trustees. The dean's notions of religion were so much more rational than those of his cotemporary priests, that they deemed him little better than a heretic; and on that account he was so frequently molested, that he at last determined to spend the rest of his days in peaceful retirement. With this intention he built a house near the palace at Richmond; but, being seized with the sweating sickness, he died in 1519, in the 52^d year of his age. He was buried on the south side of the choir of St Paul's; and a stone was laid over his grave, with no other inscription than his name. Besides the preferments above-mentioned, he was rector of the guild of Jesus at St Paul's, and chaplain to king Henry VIII. Dean Colet, though a papist, was an enemy to the gross superstitions of the church of Rome. He disapproved auricular confession, the celibacy of the priests, and such other ridiculous tenets and ceremonies as have ever been condemned by men of sound understanding in every age and country. He wrote 1. Rudimenta grammatices. 2. The construction of the eight parts of speech. 3. Daily devotions. 4. Epistolæ ad Erasmus. 5. Several sermons; and other works which still remain in manuscript.

COLIAS, in ichthyology. See COMBER.

COLIC, a severe pain in the lower venter, so called because the colon was formerly supposed to be the part

part affected. See (*the Index subjoined to*) MEDICINE.

COLIC, in farriery. See there, § xiii.

COLIGNI (Gaspard de), admiral of France, was born in 1516. He signalized himself in his youth, in the reigns of Francis I. and Henry II. and was made colonel of infantry and admiral of France in 1552. Henry II. employed him in the most important affairs; but after the death of that prince he embraced the reformed religion, and became the chief of the Protestant party: he strongly opposed the house of Guise, and rendered this opposition so powerful, that it was thought he would have overturned the French government. On the peace made after the battles of Jarnac and Montcontour, Charles IX. deluded Coligni into security by his deceitful favours; and though he recovered one attempt on his life, when he attended the nuptials of the prince of Navarre, yet he was included in the dreadful massacre of the Protestants on St Bartholomew's-day 1572, and his body treated with wanton brutality by a misguided Popish populace.

COLIR, an officer in China, who may properly be called an inspector, having an eye over what passes in every court or tribunal of the empire.

In order to render him impartial, he is kept independent, by having his post for life. The power of the collirs is such, that they make even the princes of the blood tremble.

COLIMA, a sea-port town of Mexico in North America, and capital of a fertile valley, of the same name. It is seated at the mouth of a river in W. Long. 109.6. N. Lat. 18.30.

COLIOURE, a small, but ancient and strong town of France, in Roussillon, seated at the foot of the Pyrenean mountains, with a small harbour. E. Long. 3.10. N. Lat. 43.24.

COLISEUM, in ancient architecture, an oval amphitheatre at Rome, built by Vespasian, wherein were statues set up, representing all the provinces of the empire: in the middle whereof stood that of Rome, holding a golden apple in her hand. This structure was so large, that it would hold near 100,000 spectators.

COLITES, in natural history, a name given by some writers to a kind of pebble, found in the shape of the human penis and testes, and that either separately, or both together.

COLLAR, in Roman antiquity, a sort of chain put generally round the neck of slaves that had run away, after they were taken, with an inscription round it, intimating their being deserters, and requiring their being restored to their proper owners, &c.

COLLAR, in a more modern sense, an ornament consisting of a chain of gold, enamelled, frequently set with ciphers or other devices, with the badge of the order hanging at the bottom, wore by the knights of several military orders over their shoulders, on the mantle, and its figure drawn round their armories.

Thus, the collar of the order of the garter consists of S.S. with roses enamelled red, within a garter enamelled blue, and the George at the bottom.

Lord Mayor's COLLAR is more usually called chain. See CHAIN.

Knights of the COLLAR, a military order in the republic of Venice, called also the order of St Mark, or

the medal. It is the doge and the senate that confer this order; the knights bear no particular habit, only the collar, which the doge puts around their neck, with a medal, wherein is represented the winged lion of the republic.

COLLAR of a Draught-horse, a part of harness made of leather and canvas, and stuffed with straw or wool, to be put about the horse's neck.

COLLORAGE, a tax or fine laid for the collars of wine-drawing horses.

COLLATERAL, any thing, place, country, &c. situated by the side of another.

COLLATERAL, in genealogy, those relations which proceed from the same stock, but not in the same line of ascendants or descendants, but being, as it were, aside of each other. Thus, uncles, aunts, nephews, nieces and cousins, are collaterals, or in the same collateral line: those in a higher degree, and nearer the common root, represent a kind of paternity with regard to those more remote. See CONSANGUINITY.

COLLATERAL Succession. When a defunct, for want of heirs descended of himself, is succeeded in his estate by a brother or sister, or their descendants, the estate is said to have gone to collateral heirs.

COLLATION, in the canon law, the giving or bestowing of a benefice on a clergyman by a bishop, who has it in his own gift or patronage. It differs from institution in this, that institution is performed by the bishop, upon the presentation of another; and collation is his own act of presentation: and it differs from a common presentation, as it is the giving of the church to the person, and presentation is the giving or offering of the person to the church. But collation supplies the place of presentation and institution; and amounts to the same as institution where the bishop is both patron and ordinary. Anciently the right of presentation, to all churches, was in the bishop; and now if the patron neglects to present to a church, then this right returns to the bishop by collation: if the bishop neglects to collate within six months after the elapse of the patron, then the archbishop hath a right to do it; and if the archbishop neglects, then it devolves to the king; the one as superior, to supply the defects of bishops, the other as supreme, to supply all defects of government.

COLLATION, in common law, the comparison or presentation of a copy to its original, to see whether or not it be conformable; or the report or act of the officer who made the comparison. A collated act is equivalent to its original, provided all the parties concerned were present at the collation.

COLLATION, in Scots law, that right which an heir has of throwing the whole heritable and moveable estates of the deceased into one mass, and sharing it equally with the others in the same degree of kindred, when he thinks such share will be more than the value of the heritage to which he had an exclusive title.

COLLATION is also vulgarly used for a repast between dinner and supper.

COLLEAGUE, a partner or associate in the same office or magistrature. See ADJUNCT.

COLLECT, COLLECTION, a voluntary gathering of money, for some pious or charitable purpose. See ALMS, CHARITY, &c. Some say, the name collect,

Collect
College.

or *collection*, was used, by reason those gatherings were anciently made on the days of *collects*, and in *collects*, i. e. in assemblies of Christians; but, more probably, *quia collegiatur pecunia*.

COLLECT is sometimes also used for a tax, or imposition, raised by a prince for any pious design. Thus, historians say, that in 1166, the king of England, coming into Normandy, appointed a *collect* for the relief of the holy land, at the desire and after the example of the king of France. See **CROISADE**.

COLLECT, in the liturgy of the church of England, and the mass of the Romanists, denotes a prayer accommodated to any particular day, occasion, or the like. See **LITURGY**, and **MASS**.

In the general, all the prayers in each office are called *collects*; either because the priest speaks in the name of the whole assembly, whose sentiments and desires he sums up by the word *oremus*, "let us pray," as is observed by pope Innocent III. or, because those prayers are offered when the people are assembled together, which is the opinion of Pamelius on Tertulian.

The congregation itself is in some ancient authors called *collect*. The popes Geladius and Gregory are said to have been the first who established *collects*. Despençe, a doctor of the faculty of Paris, has an express treatise on *collects*, their origin, antiquity, authors, &c.

COLLECTIVE, among grammarians, a term applied to a noun expressing a multitude, though itself be only singular; as an army, company, troop, &c. called *collective nouns*.

COLLECTOR, in general, denotes a person who gets or brings together things formerly dispersed and separated. Hence,

COLLECTOR, in matters of civil polity, is a person appointed by the commissioners of any duty, the inhabitants of a parish, &c. to raise or gather any kind of tax.

COLLECTOR, among botanists, one who gets together as many plants as he can, without studying botany in a scientific manner.

COLLEGATORY, in the civil law, a person who has a legacy left him in common with one or more other persons.

COLLEGE, an assemblage of several bodies or societies, or of several persons into one society.

College, among the Romans, served indifferently for those employed in the offices of religion, of government, the liberal and even mechanical arts and trades; so that, with them, the word signified what we call a corporation or company.

Each of these colleges had distinct meeting-places or halls; and likewise, in imitation of the state, a treasury and common chest, a register, and one to represent them upon public occasions, and acts of government. These colleges had the privilege of manumitting slaves, of being legates, and making by-laws for their own body, provided they did not clash with those of the government.

There are various colleges on foot among the moderns, founded on the model of those of the ancients. Such are the three colleges of the empire, *viz.*

COLLEGE of Electors, or their Deputies, assembled in the diet of Ratisbon.

COLLEGE of Princes; the body of princes, or their deputies, at the diet of Ratisbon.

COLLEGE of Cities, is, in like manner, the body of deputies which the imperial cities send to the diet.

COLLEGE of Cardinals, or the **Sacred COLLEGE**; a body composed of the three orders of cardinals. See **CARDINALS**.

COLLEGE is also used for a public place endowed with certain revenues, where the several parts of learning are taught.

An assemblage of several of these colleges constitute an university. The erection of colleges is part of the royal prerogative, and not to be done without the king's licence.

The establishment of colleges or universities, is a remarkable period in literary history. The schools in cathedrals and monasteries confined themselves chiefly to the teaching of grammar. There were only one or two masters employed in that office. But, in colleges, professors are appointed to teach all the different parts of science. The first obscure mention of academical degrees in the university of Paris, (from which the other universities in Europe have borrowed most of their customs and institutions), occurs A. D. 1215.

COLLEGE of Civilians, commonly called *Doctors-commons*, founded by Dr Harvey, dean of the arches, for the professors of the civil law residing in the city of London. The judges of the arches, admiralty, and prerogative court, with several other eminent civilians, commonly reside here.

To this college belong 34 proctors, who make themselves parties for their clients, manage their causes, give licences for marriages, &c.

In the common-hall of Doctors-commons are held several courts, under the jurisdiction of the civil law; particularly the high court of admiralty, the court of delegates, the arches court of Canterbury, and the prerogative court of Canterbury, whose terms for sitting are much like those at Westminster, every one of them holding several court-days; most of them fixed and known by preceding holidays, and the rest appointed at the judge's pleasure.

COLLEGE of Physicians, a corporation of physicians in London, whose number, by charter, is not to exceed 50. The chief of them are called fellows; and the next candidates, who fill up the places of fellows as they become vacant by death, or otherwise. Next to these are the honorary fellows; and lastly, the licentiates; that is, such as being found capable, upon examination, are allowed to practise physic.

This college has several great privileges granted by charter and acts of parliament. No man can practise physic in, or within seven miles of, London, without licence of the college, under the penalty of *s. l.* Also, persons practising physic in other parts of England are to have letters testimonial from the president and three elects, unless they be graduate physicians of Oxford or Cambridge. Every member of the college is authorized to practise surgery in London or elsewhere; and that they may be able at all times to attend their patients, they are freed from all parish-offices.

The college is governed by a president, four censors, and 12 electors. The censors have, by charter, power

College. power to survey, govern, and arrest all physicians, or others, practising physic in or within seven miles of London; to fine, amerce, and imprison them at discretion; to search apothecaries shops, &c. in and about London; to see if their drugs, &c. be wholesome, and the composition according to the form prescribed by the college in their dispensaries; and to burn, or otherwise destroy, those that are defective or decayed, and not fit for use.

In 1696, 42 members of the college made a subscription, to let on foot a dispensary for the relief of the sick poor, who are advised gratis every day but Sunday, and have medicines sold at the intrinsic value; since this, they have erected two other dispensaries.

Edinburgh COLLEGE of Physicians was erected on the 29th November 1681. The design of this institution was, to prevent the abuses daily committed by foreign and illiterate impostors, quacks, &c. For this reason, his majesty, at the time above-mentioned, granted letters patent to erect into a body corporate and politic, certain physicians in Edinburgh and their successors, by the title of "the President and Royal College of Physicians at Edinburgh," with power to chuse annually a council of seven, one whereof to be president; these are to elect a treasurer, clerk, and other officers; to have a common seal; to sue, and be sued; to make laws for promoting the art of physic, and regulating the practice thereof, within the city of Edinburgh, town of Leith, and districts of the Canon-gate, West-port, Pleasance, and Potter-row; through all which the jurisdiction of the college extends. Throughout this jurisdiction, no person is allowed to practise physic, without a warrant from the college, under the penalty of 5*l*. sterling the first month, to be doubled monthly afterwards while the offence is continued; one half of the money arising from such fines to go to the poor, the other to use of the college. They are also empowered to punish all licentiates in physic within the above-mentioned bounds, for faults committed against the institutions of the college; and to fine them of sums not exceeding 40*s*. On such occasions, however, they must have one of the bailies of the city to sit in judgment along with them, otherwise their sentence will not be valid. They are also empowered to search and inspect all medicines within their jurisdiction, and throw out into the street all such as are bad or unwholesome. That they may the better attend their patients, they are exempted from watching, warding, and serving on juries. They are, however, restrained from erecting schools for teaching the art of physic, or conferring degrees on any person qualified for the office of a physician; but are obliged to license all such as have taken their degrees in any other university, and to admit as honorary members all the professors of physic in the rest of the universities of Scotland. These privileges and immunities are not, however, to interfere with the rights and privileges of the apothecary-surgeons, in their practice of curing wounds, contusions, fractures, and other external operations.

Edinburgh COLLEGE of Surgeons. This is but a very late institution, by which the surgeons of Edinburgh are incorporated into a *Royal College*, and autho-

rised to carry into execution a scheme for making provision for their widows and children, &c.

COLLEGE of Justice, the supreme civil court of Scotland; otherwise called *Court of session*, or, of *council and session*. See LAW, Part III. N^o clvii. 4.

Sion COLLEGE, or the college of the London clergy, was formerly a religious house, next to a hospital; and now it is a composition of both, viz. a college for the clergy of London, who were incorporated in 1631, at the request of Dr White, under the name of the President and Fellows of Sion-college; and an hospital of 10 poor men; the first within the gates of the house, and the latter without.

This college consists of a president, two deans, and four assistants, who are annually chosen from among the rectors and vicars in London, subject to the visitation of the bishop. They have one of the finest libraries in England, built and stocked by Mr Simpson, chiefly for the clergy of the city, without excluding other students on certain terms; they have also a hall with chambers for the students, generally filled with the ministers of the neighbouring parishes.

Gresham-COLLEGE, or *COLLEGE of Philosophy*, a college founded by Sir Thomas Gresham, who built the Royal-exchange; a moiety of the revenue whereof he gave in trust to the mayor and commonalty of London and their successors for ever, and the other moiety to the company of mercers; the first to find four able persons to read in the college, divinity, astronomy, music, and geometry; and the last, three or more able men to read rhetoric, civil-law, and physic; a lecture upon each subject is to be read in turn-time, every day, except Sundays, in Latin, in the forenoon, and the same in English in the afternoon; only the music-lecture is to be read alone in English. The lecturers have each 50*l*. *per annum*, and a lodging in the college.

In this college formerly met the royal society; that noble academy, celebrated throughout the world for their improvements in natural knowledge. See SOCIETY.

COLLEGE of Herald's, commonly called the *Herald's Office*; a corporation founded by charter of king Richard III. who granted them several privileges, as to be free from subsidies, tolls, offices, &c. They had a second charter from king Henry VI.; and a house built near Doctors-commons, by the earl of Derby, in the reign of king Henry VII. was given them by the duke of Norfolk, in the reign of queen Mary, which house is now rebuilt.

This college is subordinate to the earl-marshal of England. They are assistants to him in his court of chivalry, usually held in the common-hall of the college, where they sit in their rich coats of his majesty's arms. See HERALD.

COLLEGIATE, or *COLLEGIAL*, churches are those which have no bishop's fee, yet have the ancient revenue of the bishop, the *canons* and *prebends*. Such are Westminster, Rippon, Windsor, &c. governed by deans and chapters.

Of these collegiate churches there are two kinds; some of royal, and others of ecclesiastical foundation; each of them, in matters of divine service, regulated in the same manner as the cathedrals. There are even

College
|
Collegiate.

Collet
Collier.

even some collegiate churches that have the episcopal rights. Some of these churches were anciently abbeys, which in time were secularized. The church of St Peter's, Westminster, was anciently a cathedral; but the revenues of the monastery being by act of parliament Elizabeth vested in the dean and chapter, it commenced a collegiate church. In several causes the tyling it *cathedral*, instead of *collegiate*, church of Westminster, has occasioned error in the pleadings.

COLLET, among jewelers, denotes the horizontal face or plane at the bottom of brilliants. See BRILLIANT.

COLLET, in glass-making, is that part of glass vessels which sticks to the iron instrument wherewith the metal was taken out of the melting-pot: these are afterwards used for making green glass.

COLLETICS, in pharmacy, denote much the same with AGGLUTINANTS or VULNERARIES.

COLLIER (Jeremy), a learned English nonjuring divine, born in 1650, and educated in Caius college Cambridge. He had first the small rectory of Amp-ton, near St Edmund's Bury in Suffolk; which in six years he resigned, to come to London, in 1685, where he was made lecturer of Gray's-Inn: but the change of government that followed, soon rendered the public exercise of his function impracticable. He was committed to Newgate for writing against the revolution; and again, for carrying on a correspondence which that change of events made treasonable; but was released both times, without trial, by the intervention of friends. It is observable that he carried his scruples so far, as to prefer confinement to the tacit acknowledgment of the jurisdiction of the court by accepting his liberty upon bail. Suitable to these principles, he next acted a very extraordinary part with two other clergymen of his own way of thinking, at the execution of Sir John Friend and Sir William Perkins for the assassination plot; by giving them solemn absolution, and by imposition of hands: absconding for which, he continued under an outlawry to the day of his death in 1726. These proceedings having put a stop to his activity, he employed his retired hours rather more usefully in literary works. In 1698, he attempted to reform our theatrical entertainments, by publishing his *Short view of the immorality and profaneness of the English stage*; which engaged him in a controversy with the wits of the time: but as Mr Collier defended his censures not only with wit, but with learning and reason, it is allowed that the decorum observed, for the most part, by succeeding dramatic writers, has been owing to his animadversions. He next undertook a translation of Moreri's great Historical and Geographical Dictionary; a work of extraordinary labour, and which appeared in 4 vols. folio. After this he published "An Ecclesiastical History of Great Britain, chiefly of England," in 2 vols folio; which is allowed to be written with great judgement, and even with impartiality. He was besides engaged in several controversies, which his conduct and writing gave rise to, not material to mention. In queen Anne's reign, Mr Collier was tempted, by offers of considerable preferment, to a submission; but, as he was a nonjuror upon principle, he could not be brought to listen to any terms.

COLLIER, or COALLIER. See COALLIER.
COLLIERY, COALERY, or COALLIER. See COALERY.

COLLINS (Anthony), a polemical writer, born at Heffen near Hounslow in the county of Middlesex in 1676, was the son of Henry Collins, a gentleman of about L. 1500 a-year. He was first bred at Eaton college, and then went to King's-college Cambridge, where he had for his tutor Mr Francis Hare, afterwards bishop of Chichester. He was afterwards a student of the Temple; but not relishing the law, soon abandoned that study. He was an ingenious man, and author of several curious books. His first remarkable piece was published in 1707, "An Essay concerning the use of reason in propositions, the evidence whereof depends on human testimony." In 1702, he entered into the controversy between Mr Clark and Mr Dodwell, concerning the immortality of the soul. In 1713, he published his discourse on free-thinking; which made a prodigious noise. In 1715, he retired into the county of Essex, and acted as a justice of peace and deputy lieutenant for the same county, as he had done before for that of Middlesex and liberty of Westminster. The same year, he published a "Philosophical Essay concerning human liberty." In 1718, he was chosen treasurer of the county of Essex; and, this office he discharged with great honour. In 1724, he published his "Historical and critical Essay on the 39 articles." Soon after, he published his "Discourse of the grounds and reasons of the Christian religion;" to which is prefixed, "An Apology for free debate and liberty of writing;" which piece was immediately attacked by a great number of writings. In 1726, appeared his "Scheme of literal prophecy considered, in a view of the controversy occasioned by a late book entitled, A discourse of the grounds, &c." In this discourse, he mentions a MS. dissertation of his to shew the Sibylline oracles to be a forgery made in the times of the primitive Christians, who, for that reason, were called *Sibyllists* by the Pagans; but it never appeared in print. His scheme of literal prophecy was replied to by several writers; and particularly by Dr John Rogers in his "Necessity of divine revelation asserted." In answer to which, our author wrote "A letter to the Reverend Dr Rogers, on occasion, &c." His health began to decline some years before his death, and he was very much afflicted with the stone, which at last put an end to his life at his house in Harley Square in 1729. He was interred in Oxford chapel, where a monument was erected to him, with an epitaph in Latin. His curious library was open to all men of letters, to whom he readily communicated all the assistance in his power; he even furnished his antagonists with books to confute himself, and directed them how to give their arguments all the force of which they were capable. He was remarkably averse to all indecency and obscenity of discourse; and was, independent of his scepticism, a sincerely good man.

COLLINS (John), an eminent accountant and mathematician, born in 1624, and bred a bookseller at Oxford. Besides several treatises on practical subjects, he communicated some curious papers to the royal society, of which he was a member, which are to be found

Collier
Collins.

Collins
Collinson.

found in the early numbers of their Philosophical Transactions: and was the chief promoter of many other scientific publications in his time. He died in 1683; and about 25 years after, all his papers coming into the hands of the learned William Jones, Esq; F. R. S. it appeared that Mr Collins held a constant correspondence for many years with all the eminent mathematicians; and that many of the late discoveries in physical knowledge, if not actually made by him, were yet brought forth by his endeavours.

COLLINS (William), an admirable poet, was born at Chichester, about the year 1724. He received his classical education at Winchester; after which he studied at New college, in Oxford, was admitted a commoner of King's college in the same university, and was at length elected a deny of Magdalene college. While at Oxford, he applied himself to the study of poetry, and published his Oriental Eclogues; after which, he came to London. He was naturally possessed of an ear for all the varieties of harmony and modulation; his heart was susceptible of the finest feelings of tenderness and humanity, and was particularly carried away by that high enthusiasm which gives to imagination its strongest colouring; and he was at once capable of soothing the ear with the melody of his numbers, of influencing the passions by the force of the pathos, and of gratifying the fancy by the luxury of description. With these powers, he attempted lyric poetry; and in 1746, published his Odes, descriptive and allegorical: but the fate of this work being not at all answerable to its merit, he burnt the remaining copies in indignation. Being a man of a liberal spirit and a small fortune, his pecuniary resources were unhappily soon exhausted; and his life became a miserable example of necessity, indolence, and dissipation. He projected books which he was well able to execute; and became in idea an historian, a critic, and a dramatic poet; but wanted the means and encouragement to carry these ideas into execution. Day succeeded day, for the support of which he had made no provision; and he was obliged to subsist, either by the repeated contributions of a friend, or the generosity of a casual acquaintance. His spirits became oppressed, and he sunk into a sullen despondence. While in this gloomy state of mind, his uncle colonel Martin died, and left him a considerable fortune. But this came too late for enjoyment; he had been so long harassed by anxiety and distress, that he fell into a nervous disorder, which at length reduced the finest understanding to the most deplorable childishness. In the first stages of this disorder, he endeavoured to relieve himself by travelling, and passed into France; but the growing malady obliged him to return; and having continued, with short intervals, in this pitiable state till the year 1756, he died in the arms of his sister. The ingenious Mr Longhorne has published his poetical works, with memoirs of the author, in one volume duodecimo.

COLLINSON (Peter), fellow of the royal society, descended from an ancient family in the north, was born in 1693: he was bred a quaker, and being, with a brother James, educated to the business of men-mercens, they entered into that trade in partnership. Peter, while a youth, discovered a strong

attachment to natural history; and his diligent curiosity introduced him to an acquaintance with Derham, Woodward, Sir Hans Sloane, and other eminent naturalists. Beside this propensity, his knowledge in the antiquities of his own country was so considerable, that he was a member of the society of antiquarians from its first institution; and was elected a member of the royal society in 1728: he was a most diligent associate in both, furnishing, and procuring, many valuable articles of intelligence, relating to the particular objects of their inquiries, as well at home as abroad. Among his many correspondents was the celebrated Linnæus, with whom, during his residence in England, he contracted an intimate friendship. As his mercantile connections were chiefly in North America, so he interested himself in whatever might promote the advantage of that country. In the year 1730, when a subscription library was negotiating at Philadelphia, Mr Collinson not only made several valuable presents himself, but procured others from his friends: and transmitted over to the directors of this library, among whom was Dr Franklin, the earliest account of every new improvement in agriculture and the arts. He was the first who sent over accounts, in 1745, of the new experiments in electricity, which had been made in Germany, together with a glass tube; which were the first notices Dr Franklin received on a subject he afterward so much excelled in himself. Without any pretensions to what is generally called *learning*, Mr Collinson knew more, both of nature and art, than nine out of ten who pride themselves in the possession of it. He was no less distinguished by his virtues in private life, than by his knowledge; and died of a supression of urine in 1768.

COLLINSONIA, in botany, a genus of the monogynia order belonging to the decandria class of plants. There is but one species, a native of North America, but possessed of no remarkable properties.

COLLIQUAMENTUM, in natural history, an extreme transparent fluid in an egg, observable after two or three days incubation, containing the first rudiments of the chick. It is included in one of its own proper membranes; distinct from the albumen. Harvey calls it the *oculus*.

COLLIQUATION, in chemistry, is applied to animal, vegetable, and mineral substances, tending towards fusion. See FUSION.

COLLIQUATION, in phisic, a term applied to the blood, when it loses its crasis or balsamic texture; and to the solid parts, when they waste away, by means of the animal fluids flowing off through the several glands, and particularly those of the skin, faster than they ought: which occasions fluxes of many kinds, but mostly profuse, greasy, and clammy sweats.

COLLIQUATIVE FEVER, in phisic, a fever attended with a diarrhoea, or with profuse sweats.

COLLISION, the striking of one hard body against another; or the friction or percussion of bodies moving violently with different directions, and dashing against each other.

COLLUSION, in law, a secret understanding between two parties, who plead or proceed fraudulently against each, to the prejudice of a third person.

Collinsonia
Collusion.

Collum

Cologne.

COLLUM, the same with **NECK**.

COLLYRIUM, in pharmacy, a topical remedy for disorder of the eyes; designed to cool and repel hot sharp humours.

They are generally of two kinds; the one liquid, and the other dry. Liquid collyria are composed of ophthalmic powders in waters; as rose-water, plantain-water, or that of fennel, eye-bright, &c. where in tutty, white vitriol, or some other proper powder, is dissolved.

The dry collyrium is troches of rhasis, sugar-candy, tutty prepared, &c. blown into the eye.

COLMAR, a considerable town of France, in Upper Alsace, of which it is the capital. It has great privileges, and the Protestants have liberty of conscience. It is seated near the river Ill, in E. Long. 7. 16. N. Lat. 48. 5.

COLMARS, a town of France in Provence, and the diocese of Sens. It is seated near the Alps, in E. Long. 6. 25. N. Lat. 44. 17.

COLMOGOROD, a town of the empire of Russia, with an archbishop's see, seated in an island formed by the river Divina, in E. Long. 23. 30. N. Lat. 36. 32.

COLNBROOK, a town of Buckinghamshire in England, seated on the river Coln, which separates this county from Middlesex. It is a great thoroughfare on the western road, and has several good inns. W. Long. 0. 19. N. Lat. 51. 30.

COLNE, a town of Lancashire in England, seated on a small hill near the confines of the county. W. Long. 2. 2. N. Lat. 53. 45.

COLOCHINA, an ancient town of the Morea in Turkey in Europe. E. Long. 23. 2. N. Lat. 36. 32.

COLOCYNTHIS, in botany. See **CUCUMIS**.

COLOCZA, a town of Hungary, seated on the Danube, and capital of the county of Bath, with an archbishop's see. It was taken by the Turks in 1686, but afterwards retaken by the Imperialists. E. Long. 19. 42. N. Long. 46. 33.

COLOGNA, a town of Italy in Padua, and in the territory of Venice. E. Long. 11. 43. N. Lat. 45. 39.

COLOGNE (the archbishoprick or diocese of) is one of the states that compose the electoral circle of the Rhine, in Germany. It is bounded on the north by the duchy of Cleves and Gueldres, on the west by that of Juliers, on the south by the archbishoprick of Cleves, and on the east by the duchy of Berg, from which it is almost wholly separated by the Rhine. This country is very fruitful in corn and wine, which the inhabitants dispose of by embarking it on the Rhine, it extending about seventy miles along that river. It is divided into the Higher and Lower Diocese; the Higher Diocese contains that part which lies above Cologne, wherein is Bonne, the capital town of this electorate, and where the elector resides; besides which there are Leichnich, Andernach, Bruyl, Zulich, and Kerpen. The Lower Diocese is on the other side of Cologne, and contains the towns of Zonz, Neufs, Heizarwart, Kempen, Rhyenberg, and Alpen. The city of Cologne and county of Meurs, though within the diocese of Cologne, do not belong to it; for Cologne is a free city, and Meurs belongs to the house of Nassau-Orange; but, by way of re-

compence, the elector has considerable possessions in Westphalia, which they call the *Domain*. It contains the duchy of Westphalia and the county of Reclinchusen. This prelate is one of the electors of the empire, and holds alternately with that of Treves the second or third rank in the electoral college. He is arch-chancellor of the empire in Italy; which dignity was very important when the emperors were masters of Italy, but now it is next to nothing. When the emperors were crowned at Aix la Chapelle, the archbishop of Cologne performed the ceremony, which caused him to pretend to the same right elsewhere; but he was opposed by the archbishop of Mentz. This occasioned an order, that they should each of them have that honour in their own diocese, but if it was done elsewhere, they should perform it alternately. The archbishop of Cologne is elected by the chapter in that city, which is the most illustrious in all Germany. They are all princes or counts, except eight doctors, who have no occasion to prove their nobility.

COLOGNE, an ancient and celebrated town of Germany, in the diocese of that name, with an archbishop's see, and a famous university, seated on the river Rhine, in E. Long. 6. 38. N. Lat. 50. 50. In the times of the Romans, this city was called *Colonia Agrippina*, and *Ubiarum*, because it was built by Agrippina the wife of Claudius I. and mother of Nero; and because the Ubii inhabited this country on the Lower Rhine. In 755, it was an archbishopric, and in 1260 entered into the Hanseatic league. The university was established in 1383 by Pope Urban VI. The city is fortified with strong walls, flanked by 83 large towers, and surrounded with three ditches; but these fortifications being executed after the ancient manner could make but a poor defence at present. It lies in the shape of a half-moon, and is said to have 20 gates, 19 parishes, 37 monasteries, and 365 churches and chapels; but the streets in general are dirty and badly paved, the windows of the houses composed of small bits of round glass, and the inhabitants are but few for so large a place. It is inhabited mostly by Papists; but there are also many Protestants, who repair to the neighbouring town of Mulheim, in the duchy of Berg, for public worship. Its trade, which is considerable, especially in Rhenish wine, is chiefly in the hands of Protestants, and carried on by the Rhine. The ships with which they trade to the Netherlands are of a particular form, and considerable burthen. The clergy here are very numerous, and have large revenues. That of the archbishop is L. 130,000. Baron Pelnitz says, that though Cologne is one of the greatest cities, it is one of the most melancholy in all Europe; there being nothing to be seen but priests, friars and students, many of whom beg alms with a song; and nothing to be heard but the ringing of bells: that there are very few families of quality; that the vulgar are very clownish; and that the noblemen of the chapter stay no longer in town than their duty obliges them. Mr Wright, in his travels, says, that the women go veiled; and that the best gin is that distilled from the juniper berries which grow in this neighbourhood. This city is perhaps the most remarkable of any in the world for the great numbers of precious relics it contains,

Cologne.

Cologne.

tains, of which the Popish clergy, no doubt, make their advantage. In the church of St Ursula, they pretend to shew her tomb, and the bones of the 11,000 pretended virgin martyrs, though that story is entirely owing to a mistaken inscription. The heads of some of these imaginary martyrs are kept in cases of silver, others are covered with stuffs of gold, and some have caps of cloth of gold and velvet. Brevat says, he saw between 4 and 5000 skulls, decked with garlands, and coronets, ranged on shelves. The canonesse of St Ursula, who must be all countesses, have a handsome income. In their church they pretend to shew three of the thorns of our Saviour's crown, and one of the vessels which contained the water that he converted into wine at the marriage of Cana. In the church of St Gereon are 900 heads of Moorish Cavaliers, said to have been in the army of Constantine before it was converted, and to have been beheaded for refusing to sacrifice to idols. Every one of the heads has a cap of scarlet, adorned with pearls. In the magnificent cathedral of St Peter, the three wife men who came from the east to visit our Saviour, are said to be interred. They lie in a large purple shrine spangled with gold, set upon a pedestal of brais, in the midst of a square mausoleum, faced within and without with marble and jasper. It is opened every morning at nine o'clock, if two of the canons of the cathedral are present, when these kings or wise men are seen lying at full length, with their heads bedecked with a crown of gold garnished with precious stones. Their names, which are *Gasper, Melchior, and Balthasar*, are in purple characters on a little grate, which is adorned with an infinite number of large rich pearls and precious stones, particularly an oriental topaz as big as a pigeon's egg, and valued at above 30,000 crowns. Over against them are six large branches of silver, with wax candles, which burn night and day. The bones of these men, we are told, were brought to Constantinople by Helena mother to Constantine; from thence to Milan by Eustorgius bishop of that see, and afterwards hither by archbishop Rainold. In the Jesuits college are the portraits of the first 13 generals of that order, with Ignatius Loyola at their head; and in the church, which is the finest in Cologne, are many rich statues, with an amazing quantity of fine silver plate; and the utensils for mass are all of gold enriched with precious stones. In the Cordeliers church, is the tomb of the famous Dons Scotus, surnamed *Doflor Subtilis*, with this epitaph, "Scotia me genuit, Anglia me suscepit, Gallia me docuit, Colonia me tenet." Cologne is a free imperial, and as such has a seat and voice at the diets of the empire, and circle of the Lower Rhine. In those of the empire, it has the first place on the Rhenish bench. Towards the defence of the empire, its assessment is 825 florins; and towards the maintenance of the chamber-count, 405 rix-dollars, 72 kruitzers each term. Its militia consists of four companies of foot, who keep guard at the gates. It is governed by its own senate, in respect to civil matters and causes; but the criminal jurisdiction belongs to the elector and his chapter; and so jealous are the inhabitants of him, that they will not permit him to stay in the city above three days at a time, nor to come

into it with a large retinue. For this reason the elector resides commonly at Bonn.

COLOGNE-EARTH, a kind of very light bastard ochre, of a deep brown colour.

COLOMBO, a handsome, pleasant, and strong town of Asia, seated on the eastern side of the island of Ceylon in the East Indies. It was built by the Portuguese in 1638; and in 1658, they were driven from it by the natives, assisted by the Dutch, who are now in possession of it. It is about three quarters of a mile long, and as much in breadth. The natives live in the old town, without the walls of the new: the streets of this last are wide and spacious; and the buildings are in the modern taste, particularly the governor's house which is a handsome structure. E. Long. 80. 25. N. Lat. 7. 0.

COLOMEY, or **COLOMIA**, a town of Poland in Red Russia, seated on the river Pruth, in E. Long. 25. 9. N. Lat. 48. 45.

COLOMNA (Fabio), a very learned botanist, born at Naples about the year 1567. He became skilled in the languages, in music, designing, painting, and the mathematics; and died about the middle of the 17th century. He wrote, 1. *Περὶ βοτανῶν*, seu Plantarum aliquot (ac pilicum) historia. 2. *Minus cognitarum rariorumque stirpium ἱεράσιαι*; itemque de aquatilibus, aliisque nonnullis animalibus, libellus; and other works.

COLON, in anatomy, the first and most considerable of the large intestines. See **ANATOMY**, under n^o 354.

COLON, in grammar, a point, or character formed thus [:], serving to mark a pause, and to divide the members of a period. See **POINTING**; see also **PERIOD**, **COMMA**, and **SEMICOLON**. Grammarians generally assign the use of a colon to be, to mark the middle of a period; or to conclude a sense less perfect than the dot, or period:—but, a sense less perfect than the period, is an expression extremely vague and indeterminate. See **PERIOD**.

Others say, a colon is to be used when the sense is perfect, but the sentence not concluded:—but neither is this over clear and express.

A late author, in an ingenious discourse, *De ratione interpungendi*, marks the office of the colon, and wherein it differs from the semicolon, &c. more precisely. A colon, on his principles, serves to distinguish those conjunct members of a sentence, which are capable of being divided into other members; whereof one, at least, is conjunct. Thus, in the sentence, *As we cannot discern the shadow moving along the dial-plate, so the advances we make in knowledge are only perceived by the distance gone over*; the two members being both simple, are only separated by a comma. In this, *As we perceive the shadow to have moved, but did not perceive it moving; so our advances in understanding, in that they consist of such minute steps, are only perceivable by the distance*;—the sentence being divided into two equal parts, and those conjunct ones, since they include others; we separate the former by a semicolon, and the latter by commas. But in this, *As we perceive the shadow to have moved along the dial, but did not perceive it moving; and it appears the grass has grown, though no body ever saw it grow: so the ad-*

Cologne

Colonel
|
Colony.

vances we make in knowledge, as they consist of such minute steps, are only perceivable by the distance—the advancement in knowledge is compared to the motion of a shadow, and the growth of grass; which comparison divides the sentence into two principal parts: but since what is said of the movement of the shadow, and likewise of the growth of grass, contains two simple members, they are to be separated by a femicolon; consequently, a higher pointing is required to separate them from the other part of the sentence, which they are opposed to: and this is a colon. See PUNCTUATION.

COLONEL, in military matters, the commander in chief of a regiment, whether horse, foot, or dragons.

A colonel may lay any officer of his regiment in arrest, but must acquaint the general with it; he is not allowed a guard, only a centry from the quarter-guard.

COLONEL-Lieutenant, he who commands a regiment of guards, whereof the king, prince, or other person of the first eminence, is colonel. These colonel-lieutenants have always a colonel's commission, and are usually general officers.

Lieutenant-COLONEL, the second officer in a regiment, who is at the head of the captains, and commands in the absence of the colonel.

COLONNA, a town of Italy, in the campagna of Rome, 18 miles eastward of that city. E. Long. 15. 15. N. Lat. 42. 0.

COLONNA (Pompey), cardinal archbishop of Montreal in Sicily, and bishop of a very great number of places, made a conspicuous figure in the world. He was equally qualified to wear the cardinal's hat and the helmet, and experienced more than once the reverses of fortune. Julius II. removed him from all his dignities; but Leo I. restored him, created him cardinal, and sent him on several embassies. Clement VII. divested him of the purple, and again restored him to it. It was pretended he was obliged to him for his exaltation to the papal throne. The pope refusing him some request, he reproached him, saying, "That it was by his interest he had arrived at his dignity." The pope replied, "It is true, but let me be pope, and do not endeavour to be so yourself; for by acting as you do, you endeavour to dispossess me of that you have raised me to." He died viceroy of Naples in 1532. He wrote some poems in praise of Isabella Filamarini, in which he protests the chastity of his wishes. He wrote another work, *De laudibus mulierum*.

COLONNADE, in architecture, a peristyle of a circular figure; or a series of columns disposed in a circle, and insulated within side.

A *Polystyle COLONADE*, is that whose numbers of columns is too great to be taken in by the eye at a single view. Such is the colonade of the palace of St Peter's at Rome, consisting of 284 columns of the Doric order, each above four feet and an half diameter, all in Tiburtine marble.

COLONSAY, one of the Hebrides or Western Islands belonging to Scotland. It comprehends that of Oronsay, from which it is only separated in time of flood, and both belong to the same proprietor, viz. Mr McNeil. See ORONSAY.

Colonn
|
Colony.

COLONUS, an husbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year to plough some part of the lord's land; and from hence comes the word *clown*, who is called by the Dutch *boor*.

COLONY, a company of people transplanted into a remote province in order to cultivate and inhabit it.

We may distinguish three kinds of colonies. First, those serving to ease or discharge the inhabitants of a country, where the people are become too numerous, so that they cannot any longer conveniently subsist.

The second are those established by victorious princes and people in the middle of vanquished nations, to keep them in awe and obedience.

The third may be called *colonies of commerce*; because, in effect, it is trade that is the sole occasion and object thereof.

It was by means of the first kind of colonies, that, some ages after the deluge, the east first, and successively all the other parts of the earth, became inhabited: and without mentioning any thing of the Phœnician and Grecian colonies, so famous in ancient history, it is notorious that it was for the establishment of such colonies, that, during the declension of the empire, those torrents of barbarous nations, issuing, for the generality, out of the north, over-run the Gauls, Italy, and the other southern parts of Europe; and, after several bloody battles, divided it with the ancient inhabitants.

For the second kind of colonies, the Romans used them more than any other people; and that to secure the conquests they had made from the west to the east. Every one knows how many cities in Gaul, Germany, Spain, and even England, value themselves on their having been of the number of Roman colonies.

There were two kinds of colonies among the Romans: those sent by the senate; and the military ones, consisting of old soldiers, broken and disabled with the fatigues of war, who were thus provided with lands as the reward of their services. See **BENEFICE**. The colonies sent by the senate were either Roman or Latin, i. e. composed either of Roman citizens or Latins. The colonies of Roman citizens had the right of suffrages; but had no part in the offices or honours of the republic. The inhabitants of Latin colonies, had no right of suffrages without an express permission. According to Ulpian, (*l. 1. D. de Cens.*) there were other colonies, which had little more than the name; only enjoying what they called *jus italicum*, i. e. they were free from the tributes and taxes paid by the provinces. Such were the colonies of Tyre, Berytus, Heliopolis, Palmyra, &c. M. Vailant has filled a volume in folio with medals struck by the several colonies, in honour of the emperors who founded them. The ordinary symbol they engraved on their medals, was either an eagle; as when the veteran legions were distributed in the colonies: or a labourer, holding a plough drawn by a pair of oxen; as when the colony consisted of ordinary inhabitants. On all the medals are seen the names of the decemviri, who held the same rank and had the same authority there as the consuls had at Rome.

Lastly, the *colonies of commerce*, are those established

Colony.

blished by the English, French, Spaniards, Portuguese, and other nations within these two last centuries, and which they continue still to establish, in several parts of Asia, Africa, and America; either to keep up a regular commerce with the natives, or to cultivate the ground, by planting sugar-canes, indigo, tobacco, and other commodities. The principal of this kind of colonies, are in the one and the other America, northern and southern; particularly Peru, Mexico, Canada, Virginia, New-England, Carolina, la Louisiana, l'Acadia, Hudson's Bay, the Antilles Islands, Jamaica, Domingo, and the other islands.—In Africa, Madagascar, Cape of Good Hope, Cape Verd, and its islands, and all those vast coasts extended thence as far as to the Red Sea.—Lastly, in Asia, the famous Batavia of the Dutch; Goa, Diu, of the Portuguese; and some other less considerable places of the English, French, and Danes.

The practice of settling commercial colonies in distant countries hath been adopted by the wisest nations of antiquity, who acted systematically upon maxims of sound policy. This appears to have been the case with the ancient Egyptians, the Chinese, the Phenicians, the commercial states of Greece, the Carthaginians, and even the Romans; for though the colonies of the latter were chiefly military, it could easily be shewn that they were likewise made use of for the purposes of trade. The savage nations who ruined the Roman empire, fought nothing but to extirpate or hold in vassalage those whom they overcame; and therefore, whenever princes enlarged their dominions at the expence of their neighbours, they had recourse to strong forts and garrisons to keep the conquered in awe. For this they have been blamed by the famous Machiavel; who labours to shew, that the settling of colonies would have been a cheaper and better method of bridling conquered countries, than building fortresses in them. John de Witt, who was one of the ablest and best statesmen that ever appeared, strongly recommended colonies; as affording a refuge to such as had been unfortunate in trade; as opening a field for such men to exert their abilities, as through want of interest could not raise themselves in their own country; and as a supplement to hospitals and other charitable foundations, which he thought in time might come to be overcharged. Some, however, have ridiculed the supposed advantages of colonies, and asserted that they must always do mischief by depopulating the mother-country. But it must be considered, that such as are inclined to leave their native country to go to a colony, would in all probability do so to go to a foreign nation. Before any colonies were lent from Britain, multitudes left this island and went to the continent, from a variety of causes. In the time of queen Elizabeth, many thousands of Brownists retired to Holland and Zealand; but no sooner did these people hear of the act of religious toleration being passed, than most of them left the dominions of the States, and went to New England.

From this example, and many others which might be adduced, it clearly appears, that colonies, so far from being the means of depopulating a state, are the very reverse, and contribute to the preservation of a

number of subjects that would otherwise be totally lost by their removal into other countries.

It would besides be no very difficult matter to shew from reason alone, that plantations are highly beneficial, as contributing more to the riches and welfare of any country, or at least of any trading country, than fixing settlements in foreign parts; and more especially in such a country as America, where vast regions may be obtained merely by establishing colonies in them. Let us consider what rendered the Portuguese heretofore rich and powerful, and what in some measure keeps them so still; is it not their plantations? If we ask the same question with regard to Spain, we must receive the same answer; and yet there is nothing more certain, than that both these nations are under vast inconveniencies with respect to their plantations: for they draw nothing from them but in fact-faction for commodities and manufactures, and yet the far greatest part, indeed almost all these commodities and manufactures, they purchase themselves from other nations; notwithstanding which prodigious obstacle, it is apparent that their plantations are not only the great and constant, but almost the sole source of their riches. This alone, to a man of sense and reflection, will afford a full conviction of the truth of what has been advanced, as to the benefit of plantations in general.

There is no shorter method with respect to our own in particular, than to consider one that has some staple commodity, which may serve as a model for the rest; and none can answer this purpose better than Virginia, one of the oldest, best cultivated, and most populous of our colonies upon the continent. It is computed that the number of souls indiscriminately may amount in Virginia to about half a million, and of these about 120,000 men, women, and children, may be white, which shews this colony is in itself a thing of prodigious importance. The next thing is to find out what advantages this country derives from such a number of its subjects dwelling there. In the first place it must be observed, that as the value of labour differs in several parts of this kingdom, so the labour of a man in most of the plantations is not only as advantageous to his native country as if he worked at home, but much more so: upon a moderate computation, we may reckon, that such a person contributes to the public stock four times as much. So that we may with reason reckon, that the white people in Virginia, one with another, produce 12l. to this nation; the reason of which will appear, when we consider the nature of their commerce more particularly. But besides this, the negroes are of great advantage to this kingdom, though of infinitely less than the white people would be, if they were employed in the same work; for every one of these poor creatures consumes yearly two hilling-hoes, two weeding-hoes, two grubbing-hoes, besides axes, saws, winbles, nails, and other iron tools and materials. On the whole, there can be no sort of question, because it appears a plain matter of fact, that these people necessarily take off the sum of 150,000l. in the commodities of this country.

This computation must seem prodigious to such as have not applied themselves to calculation; but we must

Colony.

Colony.

must consider, that the people in this colony of Virginia live exactly as we do, or rather more freely, in that generous, open, hospitable, and consequently expensive method that prevailed here in the last age. But as they are supplied both with necessaries and conveniences, with the instruments of labour, as well as the means of luxury, from England, it follows of course, that they must employ an infinite number of hands to provide these. For it is generally known, that these demands must be supplied from those handicrafts and mechanics that have most hands in their service, such as weavers, shoe-makers, hatters, iron-mongers, turners, joiners, taylor, cutlers, smiths, bakers, brewers, rope-makers, hosiery, and indeed all the mechanics in Britain, their manufactures being good merchandize in Virginia. The commodities sent thither, besides linen, silks, India goods, wine, and other foreign manufactures, are cloth, coarse and fine ferges, stuffs, bays, hats, and all sorts of haberdashers ware; hoes, bills, axes, nails, adzes, and other iron ware; cloaths ready made, knives, biscuit, flour, stockings, shoes, caps for servants, &c.

But if they employ these people, they must feed them likewise, and pay them their wages; and not only them, but those who take the pains to go between the planters and these workmen; by which we mean the agents, merchants, or factors, who, tho' fewer in number, yet have their servants and dependents, who, from the nature of their employments, expect to be paid at a better rate. Neither is this all: for when things are made and brought to the factor, they must be put into the hands of a new set of people, who are to be paid for the carriage of them. So that the most common capacity may understand how the labour of every hand in any plantation must be worth four times as much to the community of his mother-country as if he wrought at home; for if he spends so much, and pays for what he has, both of which are undeniable, his labour must produce so much. This shews the benefit of plantations to their mother-country, and how much regard and respect is due from those who manage the affairs of the mother-country, to those who live and labour for her in the plantations. But because it is not impossible we may err a little in the measure of these computations, we shall lay it down as a thing certainly to be depended upon, that every white person in Virginia, one with another, is worth to this nation 101. which will make the value of the whole plantation equal to an annuity of 1,200,000l. to Great Britain.

In order to shew how this sum, or at least the greatest part of it, is received, we must consider that the trade of Virginia, as well as that of Maryland, consists almost entirely of tobacco: for though the country would produce several excellent commodities fit for trade, yet the planters are so wholly bent on planting tobacco, that they seem to have laid aside all thoughts of other improvements. This trade is brought to such perfection, that the Virginia tobacco, especially the sweet-scented, which grows on York river, is reckoned the best in the world, and what is generally vended in Britain for the home-consumption: the other sorts, called Oronoco, and that of Maryland, are hotter in the mouth; but they turn to as good account,

being in demand in Holland, Denmark, Sweden, and Germany: it is therefore from this commodity that we are to look for the best part of that vast sum which we have mentioned.

In time of peace, there is very little less than 100,000 hogheads of tobacco exported every year from this colony; that between three and four hundred ships are employed in this trade, and upwards of 4000 seamen. If we take things upon this foot, then the 100,000 hogheads of tobacco will produce about the sum at which we have fixed the produce of this colony to the nation: but it may be said, that if we take tobacco for the commodities and manufactures that we send to Virginia, it differs very widely from an annuity, and that, instead of receiving 1,200,000l. from the persons inhabiting this plantation, we return them the most valuable things we have, for 60,000,000 pounds of tobacco, which in itself is no necessary of life, and which we might very well do without. But, to solve this difficulty, let us consider that tobacco was in use amongst us long before it was cultivated, or at least brought to perfection, as appears by king James I. writing a book against it; what we used came hither from Brazil, or from the Spanish plantations, and was actually sold here from four to 17s. a pound. In case the consumption of tobacco had become equal to what it is now, and we had been furnished with it by foreigners, it would have carried off all our commodities and manufactures into the bargain; but suppose it had fallen to 5s. a pound only, this alone would have cost us seven millions either in goods or in money. At 5s. a pound indeed, tobacco could not have grown into general use, but into frequent and common use it would have grown; and therefore it must have cost us a great deal; whence it may be justly inferred, that our home consumption is a saving of as much as the value amounts to. Besides this, we export annually 40,000 hogheads, which produces us generally 300,000 pounds, the net annual income of one commodity brought over from one of our colonies.

All the other colonies, settlements, and establishments, which we have in different parts of the world, contribute in like manner, but in different proportions, to take off the commodities and manufactures, to employ the people, to increase the shipping, and to extend the trade of this nation; and with this singular and valuable advantage, that so long as we behave towards them with the duty and tenderness of a parent, it is simply impossible that this trade should fail us, or that we should lose any part of our plantation commerce. We have already shown, how the commodities we have from thence, become, when wrought, to all intents and purposes, our own manufactures; so that the people in the colonies, and their slaves, where they have slaves, undergo all the drudgery and labour, while we subsist our own people by the manufacture of their commodities, and draw from thence annually immense profits, in which the people of the plantations have no share whatsoever. Such are the prerogatives of a mother-country, and such and so great the benefits she reaps by being so!

After having thus examined into the reason of the thing, let us next ask, *What was the condition of this country before we had any plantations?* The answer drawn

Colony.

Cajony.

drawn from history and observation must be to this effect : At the time queen Elizabeth entered upon the government, the customs produced 36,000 l. a-year ; at the restoration, they were lett to farm for 400,000 l. and produced considerably above double that sum before the revolution. The people of London, before we had any plantations, and but very little trade, were computed at about 100,000 : at the death of queen Elizabeth, they were increased to 150,000 ; and are now about six times that number. In those days we had not only our naval stores, but our ships, from our neighbours. Germany furnished us with all things made of metal, even to nails : wine, paper, linen, and a thousand other things, came from France. Portugal furnished us with furs ; all the produce of America was poured upon us from Spain ; and the Venetians and Genoese retailed to us the commodities of the East Indies at their own price. In short, the legal interest of money was 12 per cent. and the common price of our land 10 or 12 years purchase. We may add, that our manufactures were few, and those but indifferent ; the number of English merchants very small ; and our shipping much inferior to what now belong to the northern colonies. These are plain and certain facts. But, as soon as we began to extend our trade, and to make settlements abroad, the face of our affairs changed : the inhabitants of the metropolis were doubled by the end of the last period, and are again doubled before the end of this ; our shipping increased in a still greater proportion ; we coined, within 20 years after that queen's death, about five millions at the Tower ; in 20 years after that, seven ; and in the next 20 years, eight ; which are indubitable proofs that we had gained a prodigious balance of trade in our favour.

The next point to be considered is, *What our condition has been since ?* And with respect to this it may be boldly affirmed, that it has altered for the better, almost to a degree beyond credibility or computation. Our manufactures are prodigiously increased, chiefly by the demand for them in the plantations, where they at least take off one half, and furnish us with many valuable commodities for exportation. Instead of taking the quantities we were wont to do of goods from other nations, we actually export those very goods, and sometimes to the very same nations. Sugar, rum, and tobacco, are the sources of private wealth and public revenue, which would have been to many drains that would have beggared us, had they not been raised in our plantations. It is no longer in the power of the Russians to make us pay what they please for flax and hemp. The Swedes cannot compel us to pay their own price, and that too in ready money, for pitch and tar ; nor would it be in their power to distress us, should they attempt it, by raising the price of copper and iron. Logwood is sunk 75 per cent. ; indigo, and other dyeing materials, are in our power, and at moderate prices. In short, the advantages are infinite that redound to us from our American empire ; where we have at least a million of British subjects, and between 1500 and 2000 sail of ships constantly employed.

Such have been the fruits, such is the condition, of our plantations ; — or rather, such, till of late,

was their condition. The sad reverse that has taken place is well known to all our readers. For us to depict it, would be a task equally superfluous and painful. And as to what may be the issue of the unhappy contest, or what consequences may finally ensue ; these can only be the subject of our anxiety, of our hopes or fears : for clouds and darkness as yet rest upon the prospect.

The history of the British colonies, however, shows, that when colonists become numerous and opulent, it is very difficult to retain them in proper subjection to the parent state. It becomes then a question not very easily answered, how far they are entitled to the rights they had as inhabitants of the mother-country, or how far they are bound by its laws ? On this subject Mr Blackstone hath the following observations.

“ Plantations, or colonies in distant countries, are either such where the lands are claimed by right of occupancy only, by finding them desert and uncultivated, and peopling them from the mother-country ; or where, when already cultivated, they have either been gained by conquest, or ceded to us by treaties. And both these rights are founded upon the law of nature, or at least on that of nations. But there is a difference between these two species of colonies with respect to the laws by which they are bound. For it hath been held, that if an uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birthrights of every subject, are immediately there in force. But this must be understood with many and very great restrictions. Such colonists carry with them only so much of the English law as is applicable to their own situation, and the condition of an infant colony ; such, for instance, as the general rules of inheritance, and of protection from personal injuries. The artificial refinements and distinctions incident to the property of a great and commercial people, the laws of policy and revenue (such especially as are enforced by penalties) the mode of maintenance for the established clergy, the jurisdiction of spiritual courts, and a multitude of other provisions, are neither necessary nor convenient for them, and therefore are not in force. What shall be admitted, and what rejected, at what times, and under what restrictions, must, in cases of dispute, be decided in the first instance by their own provincial judicature, subject to the revision and controul of the king in council ; the whole of their constitution being also liable to be new-modelled and reformed by the general superintending power of the legislature in the mother-country. But in conquered or ceded countries, that have already laws of their own, the king may indeed alter and change those laws ; but, till he does actually change them, the ancient laws of the country remain, unless such as are against the law of God, as in an infidel country. Our American plantations are principally of this latter sort, being obtained in the last century, either by right of conquest and driving out the natives (with what natural justice I shall not at present inquire), or by treaties. And therefore, the common law of England, as such, has no allowance or authority there ; they being no part of the mother country, but distinct (though dependent) dominions. They are subject, however, to the controul of the parliament ;

Colony. parliament; though, (like Ireland, Mann, and the rest,) not bound by any acts of parliament, unless particularly named."

Colophony.

With respect to their interior polity, our colonies are properly of three sorts. 1. Provincial establishments, the constitutions of which depend on the respective commissions issued by the crown to the governors, and the instructions which usually accompany those commissions; under the authority of which, provincial assemblies are constituted, with the power of making local ordinances not repugnant to the laws of Britain. 2. Proprietary governments, granted out by the crown to individuals, in the nature of feudalitary principalities, with all the inferior regalities, and subordinate powers of legislation which formerly belonged to the owners of counties palatine: yet still, with these express conditions, that the ends for which the grant was made be substantially pursued, and that nothing be attempted which may derogate from the sovereignty of the mother-country. 3. Charter governments, in the nature of civil corporations; with the power of making bye-laws for their own interior regulation, not contrary to the laws of Britain; and with such rights and authorities as are specially given them in their several charters of incorporation. The form of government, in most of them, is borrowed from that of England. They have a governor named by the king (or, in some proprietary colonies, by the proprietor), who is representative or deputy. They have courts of justice of their own, from whose decisions an appeal lies to the king in council here in England. Their general assemblies, which are their house of commons, together with their council of state, being their upper house, with the concurrence of the king, or his representative the governor, make laws suited to their own emergencies. But it is particularly declared, by stat. 7 and 8 W. III. c. 22. that all laws, bye-laws, usages and customs, which shall be in practice in any of the plantations, repugnant to any law made or to be made in this kingdom relative to the said plantations shall be utterly void, and of none effect. And, because several of the colonies had claimed the sole and exclusive right of imposing taxes upon themselves, the statute 6 Geo. III. c. 12. expressly declares, that all his Majesty's colonies in America, have been, are, and of right ought to be, subordinate to and dependent upon the imperial crown and parliament of Great Britain; who have full power and authority to make laws and statutes of sufficient validity to bind the colonies and people of America, subjects to the crown of Great Britain in all cases whatsoever. And the attempting to enforce this by other acts of Parliament, penalties, and at last by military power, gave rise, as is well known, to the present revolt of our colonies.

COLOPHONY, in pharmacy, black resin, or turpentine, boiled in water, and afterwards dried; or, which is still better, the caput mortuum remaining after the distillation of the etherial oil, being further urged by a more intense and long continued fire.—It receives its name of *colophonia*, from Colophon, a city of Ionia; because the best was formerly brought from thence. Two sorts are mentioned in ancient writings; the one dry, the other in a liquid form. The latter

seems to have been liquid pitch, which is the crude resin of the pine brought from Colophon; the other was called *resina fricta*, and consisted only of the former deprived of its humid parts.

COLOQUINTIDA, in botany. See CUCUMIS.

COLORATURA, in music, denotes all manner of variations, trillos, diminutions, &c. serving to make a song agreeable.

COLORNO, a town of Italy, in the Parmazan, near the river Po, 8 miles from Parma. The duke of Parma has a pleasure-house here, one of the most delightful seats in all Italy, and the gardens are very fine. E. Long. 9. 15. N. Lat. 44. 54.

COLOSSUS, a statue of enormous or gigantic size. The most eminent of this kind was the *Colossus* of Rhodes; a statue of Apollo, so high, that ships passed with full sails betwixt its legs. It was the workmanship of Chares, a disciple of Lysippus; who spent 12 years in making it: it was at length overthrown by an earthquake, after having stood 1360 years. Its height was sixscore and six feet: there were few people could fathom its thumb, &c. Some critics observe, that the *Colossus* of Rhodes gave its own name to the people among whom it stood; and that many, at least among the ancient poets, call the Rhodians, *Colossians*; hence they advance an opinion, that the Colossians in scripture, to whom St Paul directs his epistle, are, in reality, the inhabitants of Rhodes. Of this sentiment are Suidas, Calepine, Munster, &c. When the Saracens became possessed of the island, the statue was found prostrate on the ground: they sold it to a Jew, who loaded 900 camels with the brass.

The basis that supported it was a triangular figure, its extremities were sustained with 60 pillars of marble. There was a winding-stair-case to go up to the top of it; from whence one might discover Syria, and the ships that went into Egypt, in a great looking-glass, that was hung about the neck of the statue. Among the antiquities of Rome, there are seven famous *Colossuses*: two of Jupiter, as many of Apollo, one of Nero, one of Domitian, and one of the Sun.

COLOSTRUM, the first milk of any animal after bringing forth young, called *breastmilk*. It is remarkable that this milk is generally cathartic, and purges the meconium; thus serving both as an aliment and medicine.

An emulsion prepared with turpentine dissolved with the yolk of an egg, is sometimes called by this name.

COLOSWAR, a large and celebrated town of Transylvania, where the senates have their meetings. It is seated on the river Samos in E. Long. 22. 45. N. Lat. 46. 53.

COLOUR, in physics, a property inherent in light, by which, according to the various sizes of its parts, or from some other cause, it excites different vibrations in the optic nerve; which propagated to the sensorium, affect the mind with different sensations. See CHROMATICS and OPTICS.

COLOUR, in painting, is applied both to the drugs, and to the tints produced by those drugs variously mixed and applied.

The principal colours used by painters are red and white lead, or ceruus; yellow and red ochres; several kinds

Coloquin-
tida
Colour.

Colour.

kinds of earth, umbre, orpiment, lamp-black, burnt ivory, black lead, cinnabar or vermilion, gamboge, lacca, blue and green ashes, verdigraese, bistre, bice, smalt, carmine, ultramarine: each of which, with their uses, &c. are to be found under their proper articles.

Of these colours some are used tempered with gum-water; some ground with oil; others only in freisco; and others for miniature.

Painters reduce all the colours they use under these two classes, of dark and light colours: dark colours are black, and all others that are obscure and earthy, as umbre, bistre, &c.

Under light colours are comprehended white, and all that approach nearest to it.

Painters also distinguish colours into simple and mineral.

Under simple colours they rank all those which are extracted from vegetables, and which will not bear the fire; as the yellow made of saffron, French berries, lacca, and other tinctures extracted from flowers, used by limners, illuminers, &c.

The mineral colours are those which being drawn from metals, &c. are able to bear the fire, and therefore used by enamellers. Changeable and permanent colours is another division, which, by some, is made of colours.

Changeable colours are such as depend on the situation of the objects with respect to the eye, as that of a pigeon's neck, taffeties, &c. the first however being attentively viewed by the microscope, each fibre of the feathers appears composed of several little squares, alternately red and green, so that they are fixed colours.

Water COLOURS, are such as are used in painting with gum-water, or size, without being mixed with oil.

Incapacity of distinguishing COLOURS. Of this extraordinary defect in vision, we have the following instances in the philosophical Transactions for 1777. One of the persons lived at Maryport in Cumberland. The account was communicated by Mr Huddart to Dr Priestley, and is as follows. "His name was Harris, by trade a shoe-maker. I had often heard from others, that he could discern the form and magnitude of all objects very distinctly, but could not distinguish colours. This report having excited my curiosity, I conversed with him frequently on the subject. The account he gave was this: That he had reason to believe other persons saw something in objects which he could not see; that their language seemed to mark qualities with precision and confidence, which he could only guess at with hesitation, and frequently with error. His first suspicion of this arose when he was about four years old. Having by accident found in the street a child's stocking, he carried it to a neighbouring house to inquire for the owner: he observed the people called it a *red* stocking, though he did not understand why they gave it that denomination, as he himself thought it completely described by being called a *stocking*. This circumstance, however, remained in his memory, and, together with subsequent observations, led him to the knowledge of his defect.

"He also observed, that when young, other chil-

dren could discern cherries on a tree, by some pretended difference of colour, though he could only distinguish them from the leaves by the difference of their size and shape. He observed also, that by means of this difference of colour they could see the cherries at a greater distance than he could, though he could see other objects at as great a distance as they, that is, where the sight was not assisted by the colour. Large objects he could see as well as other persons; and even the smaller ones if they were not enveloped in other things, as in the case of cherries among the leaves.

"I believe he could never do more than guess the name of any colour; yet he could distinguish white from black, or black from any light or bright colour. Dove or straw colour he called *white*, and different colours he frequently called by the same name, yet he could discern a difference between them when placed together. In general, colours of an equal degree of brightness, however they might otherwise differ, he confounded together. Yet a striped ribbon he could distinguish from a plain one; but he could not tell what the colours were with any tolerable exactness. Dark colours, in general, he often mistook for black; but never imagined white to be a dark colour, nor dark to be a white colour.

"He was an intelligent man, and very desirous of understanding the nature of light and colours; for which end he had attended a course of lectures in natural philosophy.

"He had two brothers in the same circumstances as to sight; and two other brothers and sisters, who, as well as their parents, had nothing of this defect.

"One of the first mentioned brothers, who is now living, I met with at Dublin, and wished to try his capacity to distinguish the colours in a prism; but not having one by me, I asked him, whether he had ever seen a rain-bow? he replied, He had often, and could distinguish the different colours; meaning only, that it was composed of different colours, for he could not tell what they were.

"I then procured, and shewed him a piece of ribbon: he immediately, and without any difficulty, pronounced it a striped, and not a plain, ribbon. He then attempted to name the different stripes: the several stripes of white he uniformly and without hesitation called white: the four black stripes he was deceived in; for three of them he thought brown, though they were exactly of the same shade with the other, which he properly called black. He spoke, however, with diffidence, as to all those stripes; and it must be owned, that the black was not very distinct: the light green he called yellow; but he was not very positive: he said, "I think this is what you call yellow." The middle stripe, which had a slight tinge of red, he called a sort of blue. But he was most of all deceived by the orange colour; of this he spoke very confidently, saying, "this is the colour of grass; this is green." I also shewed him a great variety of ribbons, the colour of which he sometimes named rightly, and sometimes as differently as possible from the true colours.

"I asked him, whether he imagined it possible for all the various colours he saw to be mere difference of

Colour.

Colour. light and shade; and that all colours could be composed of these two mixtures only? With some hesitation he replied, No, he did imagine there was some other difference.

"It is proper to add, that the experiment of the striped ribbon was made in the day-time, and in a good light."

COLOURS for staining different kinds of Stones. See CHEMISTRY, n^o 197.

COLOUR, in dyeing. See DYEING.

COLOUR of *Plants*, is an attribute found to be very variable. Different colours are observed, not only in different individuals of the same species, but likewise in different parts of the same individual. Thus, marvel of Peru, and sweet-William, have frequently petals of different colours on the same plant. Three or four different colours are frequently found upon the same leaf or flower; as on the leaves of the amaranthus, tricolor, and the flowers of the tulip, auricula, three-coloured violet, and others. To produce the most beautiful and striking variety of colours in such flowers, is the principal delight and business of the florist.

The primitive colours, and their intermediate shades or gradations enumerated by botanists, are as follow.

Water-colour, *hyalinus*.

WHITE.

Lead-colour, *cinerescens*.

BLACK, *niger*.

Brown, *fuscus*.

Pitch-black, *ater*.

YELLOW, *luteus*.

Straw-colour, *flavus*.

Flame-colour, *fulvus*.

Iron-colour, *gilvus*.

RED.

Flesh-colour, *incarnatus*.

Scarlet, *coccineus*.

PURPLE.

Violet-colour, *cœruleo-purpureus*.

BLUE, *cœruleus*.

GREEN.

These colours seem to be appropriated to particular parts of the plant. Thus, white is most common in roots, sweet berries, and the petals of spring flowers. Water-colour, in the filaments and styles. Black, in the roots and seeds; rarely in the seed-vessel, and scarce ever to be found in the petals. Yellow is frequent in the antheræ or tops of the stamina; as likewise in the petals of autumnal flowers, and the compound ligulated flowers of Linnæus. Red is common in the petals of summer flowers, and in the acid fruits. Blue and violet-colour, in the petals. Green, in the leaves and calix, but rarely in the petals. In the interchanging of colours, which in plants is found to depend upon differences in heat, climate, soil and culture, a sort of elective attraction is observed to take place. Thus, red is more easily changed into white and blue; blue into white and yellow; yellow into white; and white into purple. A red colour is often changed into a white, in the flowers of heath, mother of thyme, betony, pink, viscous campion, *cucubalus*, trefoil, orchis, fox-glove, thistle, cudweed, saw-wort,

rose, poppy, fumitory, and geranium. Red passes into blue in pimpernel. Blue is changed into white in bell-flower, greek-valerian, bindweed, columbine, violet, vetch, milk-wort, goat's rue, viper's bugloss, comfrey, borragé, hyssop, dragon's-head, scabious, blue-bottle, and fuccory. Blue is changed into yellow in crocus. Yellow passes easily into white in melilot, agrimony, mullein, tulip, *biataria*, or moth-mullein, and corn marigold. White is changed into purple in wood-forrel, thorn-apple, pease, and daisy.

Although plants are sometimes observed to change their colour upon being moistened with coloured juices, yet that quality in vegetables seems not so much owing to the nature of their nourishment, as to the action of the internal and external air, heat, light, and the primitive organisation of the parts. In support of this opinion, we may observe with Dr Grew, that there is a far less variety in the colours of roots than of the other parts of the plant, the pulp, within the skin, being usually white, sometimes yellow, rarely red. That this effect is produced by their small intercourse with the external air appears from this circumstance, that the upper parts of roots, when they happen to stand naked above the ground, are often dyed with several colours: thus the tops of forrel roots turn red; those of turnips, mullein, and radishes, purple; and many others green: whilst those parts of the same roots which lie more under ground are commonly white. The green colour is so proper to leaves, that many, as those of sage, the young sprouts of St John's wort, and others which are reddish when in the bud, acquire a perfect green upon being fully expanded. In like manner, the leaves of the sea-side grape, *polygonum*, which when young are entirely red, become, as they advance in growth, perfectly green, except the middle and transverse ribs, which retain their former colour.

As flowers gradually open and are exposed to the air, they throw off their old colour, and acquire a new one. In fact, no flower has its proper colour till it is fully expanded. Thus the purple stock-julyflowers are white, or pale in the bud. In like manner bachelor's buttons, blue-bottle, poppy, red daisies, and many other flowers, though of divers colours when blown, are all white in the bud. Nay, many flowers change their colours thrice successively; thus, the very young buds of lady's looking-glass, bugloss, and the like, are all white; the larger buds purple, or murrey; and the open flowers blue.

With respect to the colours of the juices of plants, we may observe, that most resinous gums are tinged; some, however, are limpid; that which drops from the domestic pine is clear as rock-water. The milk of some plants is pale, as in birdock; of others white, as in dandelion, euphorbium, and scorzonera; and of others yellow, as in lovage, and greatercelandine. Most mucilages have little colour, taste or smell. Of all the colours above enumerated, green is the most common to plants, black the most rare.

Colour being a quality in plants so apt to change, ought never to be employed in distinguishing their species. These ought to be characterised from circumstances not liable to alteration by culture or other accidents. The same inconstancy of colour observed

Colour.

Colour.

in the flowers, is likewise to be found in the other parts of plants. Berries frequently change from green to red, and from red to white. Even in ripe fruits, the colour, whether white, red, or blue, is apt to vary; particularly in apple, pear, plum, and cherry trees. Seeds are more constant in point of colour than the vessel which contains them. In the feeds, however, of the poppy, oats, pea, bean, and kidney-bean, variations are frequently observed. The root too, although not remarkably subject to change, is found to vary in some species of carrot and radish. Leaves frequently become spotted, as in a species of orchis, hawk-weed, ranunculus, knot-grass, and lettuce; but seldom relinquish their green colour altogether. Those of some species of amaranthus, or flower-gentle, are beautifully coloured. The spots that appear on the surface of the leaves are of different colours, liable to vary, and not seldom disappear altogether. The leaves of officinal lung-wort, and some species of fowbread, sorrel, trefail, and ranunculus, are covered with white spots. Those of dog's-tooth violet, with purple and white. Those of several species of ranunculus, and orchis, and a kind of knot-grass called by Tournefort *pescaria ferrugine quinum referens*, with black and purple. Those of amaranthus, tricolor, with green, red and yellow. Those of ranunculus acris, and a species of bog-bean, with red or purple. The under surface of the leaves of some species of pimpernel and the sea-plantain is marked with a number of dots or points; a white line runs through the leaves of Indian reed, black-berried heath, and a species of canary grass; and the margin or brim of the leaf, in some species of box, honey-suckle, ground-ivy, and the ever-green oak, is of a silver-white colour. The whole plant is often found to assume a colour that is unnatural or foreign to it. The varieties in some species of eryngo, mugwort, orrach, amaranthus, purslane, and lettuce, furnish examples.

Such being the inconstancy of colour in all the parts of the plant, specific names derived from that quality are, very properly, by Linnaeus, deemed erroneous; whether they respect the colour of the flower, fruit, seeds, root, leaves, or express in general the beauty or deformity of the entire plant, with a particular view to that circumstance. Of this impropriety committed by former botanists, Linnaeus himself is not always guiltless. Thus the two species of *sarracena*, or the side-saddle flower, are distinguished by the colour of their petals into the yellow and purple *sarracena*; although the shape and figure of the leaves afforded much more constant as well as striking characters. The fame may be said of his *lupinus albus*, and *luteus*; *reseda alba*, *glauca*, and *lutea*; *angelica atro-purpurea*; *dictamnus albus*; *laminum album*; *selago coccinea*; *sida alba*; *passiflora rubra*, *lutea*, *incarnata*, and *cœrulea*; and of many others, in which the specific name is derived from a character or quality that is so liable to vary in the same species.

We shall conclude this article with observing, that of all sensible qualities, colour is the least useful in indicating the virtues and powers of vegetables. The following general positions on this subject are laid down by Linnaeus, and seem sufficiently confirmed by ex-

periment. A yellow colour generally indicates a bitter taste; as in gentian, aloë, calandine, turmeric, and other yellow flowers. Red indicates an acid or four taste; as in cranberries, barberries, currants, rasp-berries, mulberries, cherries; the fruit of the rose, sea-buckthorn, and service-tree. Herbs that turn red towards autumn, have likewise a four taste; as sorrel, wood-sorrel, and bloody-dock. Green indicates a crude alkaline taste, as in leaves and unripe fruits. A pale colour denotes an insipid taste, as in endive, asparagus, and lettuce. White promises a sweet, luscious taste; as in white currants, and plums, sweet apples, &c. Lastly, black indicates a harsh, nauseous, disagreeable taste; as in the berries of deadly night-shade, myrtle-leaved fumach, herb-christopher and others; many of which are not only unpleasant to the taste, but pernicious, and deadly in their effects.

To be ascertained of the acid or alkaline property of any plant, express some of the juice, and rub it upon a piece of blue paper; which, if the plant in question is of an acid nature, will turn red; if of an alkaline, green. For the methods of extracting colours from the different parts of plants, see the article *COLOUR-Making*.

COLOUR of the Human Species, Difference of. Few questions in philosophy have engaged the attention of naturalists more than the diversities among the human species, among which that of colour is the most remarkable. The great differences in this respect have given occasion to several authors to assert, that the whole human race have not sprung from one original; but that as many different species of men were at first created, as there are now different colours to be found among them. Under the article *AMERICA*, n° 42—53, we have shewn that all the arguments which can be brought for specific differences among mankind, whether drawn from a difference of colour, stature, or disposition, must necessarily be inconclusive. It remains, however, a matter of no small difficulty to account for the remarkable variations of colour that are to be found among different nations. On this subject Dr Hunter hath published a thesis, in which he considers the matter more accurately than hath commonly been done, and determines absolutely against any specific difference among mankind. He introduces his subject by observing, that when the question has been agitated, whether all the human race constitute only one species or not, much confusion has arisen from the sense in which the term *species* has been adopted. He therefore thinks it necessary to set out with a definition of the term. He includes under the same species all those animals which produce issue capable of propagating others resembling the original stock from whence they sprung. This definition he illustrates by having recourse to the human species as an example. And in this sense of the term he concludes, that all of them are to be considered as belonging to the same species. And as, in the case of plants, one species comprehends several varieties depending upon climate, soil, culture, and similar accidents; so he considers the diversities of the human race to be merely varieties of the same species, produced by natural causes. Of the different colours observable among mankind, he gives the following view:

Colour.

Colour.

- BLACK.** Africans under the line.
Inhabitants of New Guinea.
Inhabitants of New Holland.
- SWARTHY.** The Moors in the northern parts of Africa.
The Hottentots in the southern parts of it.
- COPPER-COLOURED.** The East Indians.
- RED-COLOURED.** The Americans.
- BROWN-COLOURED.** Tartars.
Persians.
Arabs.
Africans on the coast of the Mediterranean.
Chinese.
- BROWNISH.** The inhabitants of the southern parts of Europe; as
Sicilians,
Abyssinians,
Spaniards,
Turks, and likewise the Samoiedes and Laplanders.
- WHITE.** Most of the European nations; as
Swedes,
Danes,
English,
Germans,
Poles, &c.
Kubardinski,
Georgians,
Inhabitants of the islands in the Pacific Ocean.

In attempting to investigate the causes of these differences, our author observes, that there can be no dispute of the seat of colour being placed in the skin; that it is not even extended over the whole of this, but confined to that part named the cuticle, consisting of the epidermis and reticulum; and that it chiefly occupies the latter of these. The cuticle is much thicker and harder in black people than in white ones; the reticulum in the latter being a thin mucus, in the former a thick membrane. He concludes that this seat of colour in whites is transparent, and either totally deprived of vessels, or only furnished with very few; as the yellow colour appearing in jaundice vanishes on the cause of the disease being removed; which is not the case with stains in the cuticle from gunpowder, or similar causes. He next points out three causes destroying the pellucidity of the cuticle, giving it a brown colour, and rendering it thicker. These are, accretions of air, nastiness, and the heat of the sun. The influence of each of these he proves by many examples; and from these he is inclined to consider the last as by much the most powerful. If, however, it be admitted that these causes have this effect, he thinks that all the diversity of colour which is to be observed among mankind, may be thus accounted for. He remarks, that all the inhabitants of the torrid zone incline more or less to a black colour. When we observe the differences which occur amongst them, we must at the same time remember, that a black colour is not referred to heat alone, but to the other causes also: and when we attend to the diversity of

Colour.

temperature that occurs even in the torrid zone, the existence of a white nation there would by no means destroy the argument. He is farther of opinion, that the existence of a brown colour, and of considerable varieties from white, in the northern and coldest parts of Europe, may very easily be explained. This he accounts for from the manner of life of the inhabitants, by which they are either exposed to the inclemency of the air, or to constant nastiness from smoky houses.

Having thus attempted to account, from natural causes, for the varieties which occur among mankind with respect to colour, our author observes, that, to all this reasoning, an objection will naturally be made, from considering that infants bring these marks into the world along with them, before they can be exposed to any such causes. Dr Hunter imagines, however, that this may readily be explained upon the supposition that many peculiarities acquired by parents are transmitted to their posterity; and of this, he thinks, no one can entertain the least doubt who attends to hereditary diseases. Thus, gout, scrophula, mania, and many other affections, although at first induced by particular accidents, will continue to affect families for many generations. In the same manner, a parent exposed to causes destroying the natural whiteness of his complexion, will beget swarthy children; and the same causes continuing to operate upon the son, the blackness will be increased. Thus all the different shades may have been at first induced, and afterwards continued.

COLOUR, in heraldry. The colours generally used in heraldry are red, blue, black, green and purple, which the heralds call gules, azure, sable, vert or sinople, and purpure; tenné or tawny, and sanguine, are not so common: as to yellow and white, called *or*, and *argent*, they are metals, not colours.

The metals and colours are sometimes expressed in blazon by the names of precious stones, and sometimes by those of planets or stars. See **BLAZONING**.

Oenomaus is said to have first invented the distinction of colours, to distinguish the gundillæ of combatants of the Circensian games; the green for those who represented the earth, and blue for those who represented the sea.

COLOURS, in the military art, include the banners, flags, ensigns, &c. of all kinds, borne in the army or fleet. See **FLAG**, and **STANDARD**.

COLOURS, in the Latin and Greek churches, are used to distinguish several mysteries and feasts, celebrated therein.

Five colours only are regularly admitted into the Latin church; these are white, green, red, violet, and black: the white is for the mysteries of our Saviour, the feasts of the virgin, those of the angels, saints, and confessors; the red is for the mysteries and solemnities of the holy sacrament, the feasts of the apostles and martyrs; the green for the time between pentecost and advent, and from epiphany to septuagesima; the violet in advent and Christmas, in vigils, rogations, &c. and in votive masses in time of war; lastly, the black is for the dead, and the ceremonies thereto belonging.

In the Greek church, the use of colours is almost abolished, as well as among us; red was, in the Greek church,

Colour-making.

church, the colour for Christmas, and the dead, as black among us.

To COLOUR *strangers goods*, is when a freeman allows a foreigner to enter goods at the custom-house in his name.

COLOUR-Making, the art of preparing the different kinds of colours used in painting.

This art properly belongs to chemistry; and is one of the most curious, though least understood, parts of it. The principles on which colour-making depends are entirely different from those on which the theory of other parts of chemistry is founded; and the practical part being in the hands of those who find it their interest to conceal their methods as much as possible, it thence happens; that there is not only no distinct theory of this art, but scarce a single good receipt for making any one colour hath ever appeared.

Division of colours into opaque and transparent.

The first general division of colours is into opaque and transparent. By the first are meant such colours as, when laid over paper, wood, &c. cover them fully so as to efface any other painting or stain that might have been there before; the others are of such a nature as to leave the ground on which they are laid, visible through them. Of the first kind are white-lead, red-lead, vermilion, &c. of the latter kind are the colours used for illuminating maps, &c.

Oil and water colours.

Another division is into oil-colours, and water-colours; by which is meant such as are appropriated to painting in oil, and in water. Most of those which are proper for painting in water, are also proper for being used in oil. There is, however, this remarkable difference betwixt colours when mixed with water and with oil, that such as are quite opaque in water, will become perfectly transparent in oil. Thus, blue verditer, though exceedingly opaque in water, if ground with oil, seems totally to dissolve, and will become very transparent. The same thing happens to such colours as have for their basis the calx of tin, alabaster, or calcareous earth. The most perfectly opaque colours in oil are such as have lead, mercury, or iron, for their basis: to the latter, however, Prussian blue is an exception; for though the basis of that colour is iron, it proves quite transparent when ground with oil. In water-colours, those prepared from metals, Prussian blue alone excepted, are always opaque; from vegetables or animals, transparent. Coals, however, whether vegetable or animal, are opaque both in water and oil.

Simple and compound tints.

Colours again may be considered as either simple or compound. The simple ones are such as require nothing to be superadded to them, in order to make a full strong colour, without regarding whether they are formed of many or few ingredients; and in this view, white-lead, red-lead, vermilion, calces of iron, &c. are simple colours. The compound ones are formed by the union of two or more colouring substances; as blue and yellow united together to form a green, red and yellow to form an orange, a white earth or calx with the red colour of cochineal or brazil, to form a lake, &c. and thus, carmine, lake, rose-pink, Dutch-pink, English-pink, &c. are compound colours.

True and false colours.

The last and most important division of colours is into true and false. By the former are meant those which retain their colour under every possible variety

of circumstances, without fading in the least: the others are such as do not; but either lose their colour altogether, or change to some other. What is chiefly apt to affect colours, is their being exposed to the sun in summer, and to the cold air in winter; but to this there is one exception, *viz.* white-lead, which, when ground with oil, retains its whiteness if exposed to the weather, but degenerates into a brownish or yellowish colour if close kept. In water this substance is very apt to lose its colour, whether exposed to the air or not. The great desideratum in colour-making is to produce the first kind of colours, *viz.* such as will not fade by exposure to the weather; and indeed it is to be regretted, that the most beautiful are in general the least permanent. It may, for the most part, however, be expected, that the more simple any colour is, the less liable will it be to change upon exposure to the air.

The great difficulty of knowing *a priori* whether a colour will fade or not, is owing to our ignorance concerning the nature of colouring substances. With all our disadvantages, however, we may observe, that whatever change of colour is produced in any substance by exposure to the sun and air, that colour to which it changes will bid fair for being permanent; and therefore ought to be employed where it can be done.

Of these changes, the instances are but very rare. One is in the purple of the ancients, which assumed its colour by exposure to the sun, and consequently was exceedingly permanent. Another is in the solution of silver, which, being mixed with chalk, the precipitate turns to purplish black where it is exposed to the sun. A third is in solutions of indigo by alkaline substances, which constantly appear green till exposed to the air by spreading them very thin, upon which they become almost instantaneously blue, and continue so ever after. Sometimes, though still more rarely, a very remarkable change of colour happens, upon mixing two vegetable juices together. Almost the only instance of this we have on the authority of Mr George Forster, who informs us that the inhabitants of Otaheite dye their cloth of a crimson-colour, by mixing together the yellow juice of a small species of fig, with the greenish juice of a kind of fern. But the most remarkable alterations of colour are effected by different metallic and saline solutions mixed with certain animal or vegetable substances; and with these the colour-maker will be principally conversant.

It is a common observation in chemistry, that acids mixed with blue vegetable juices turn them red, and alkalis, green. It is equally certain, though not so generally known, that acids of all kinds generally tend to heighten red colours, so as to make them approach to the scarlet or true crimson; and alkalis to darken, or make them approach to blue or purple. Mixed with yellow colours, acids also universally tend to brighten the yellow; and alkalis to turn it to an orange, and make it become more dull. But though this is very generally the case, we are not to expect that all acids are equally powerful in this respect. The nitrous acid is found to heighten the most of any, and the marine acid the least of the mineral ones. The vegetable, as might be expected, are less powerful than the mineral acids. Thus, if with a tincture of

cochineal.

Colour-making.

cochineal, either in water or spirit of wine, is mixed the pure nitrous acid, it will change the colour to an exceeding high orange or flame-colour, which it will impart to cloth. If the vitriolic acid is used, a full scarlet, inclining to crimson rather than orange, is produced. With marine acid a true crimson-colour, bordering on purple, is the consequence. Alkalies, both fixed and volatile, change the colour to a purple, which is brighter with the volatile than the fixed alkalies.

8

Permanency of colours, by what determined.

Here it is obvious, that whatever colours are produced by the mixtures of different substances together, the permanency of these colours can only be in proportion to the ability of such mixtures to resist the weather. Thus, suppose a full scarlet or orange colour is produced by means of spirit of nitre, it is plain that, was such a colour exposed to the air, it could remain no longer than the spirit of nitre which produced it remained. In proportion, therefore, as the spirit of nitre was exhaled into the air, or otherwise destroyed, it behaved the colour to fade, and at last to be totally destroyed; and thus, in proportion to the destructibility of the substances by which colours are produced, will be the disposition of such colours to fade, or the contrary. In this respect alkalies are much more destructible than acids, and consequently less proper for the preparation of colours. With regard to acids, the nitrous seems most destructible, the vitriolic less so, and the marine the least of all. From the extreme fixity of the phosphoric acid and sedative salt, perhaps they might be of service in preserving colours.

As all colours, whether derived from the animal or vegetable kingdom, must be extracted either by pure water or some other liquid menstruum, they cannot be used for the purposes of painting till the colouring substance is united with some earthy or solid matter, capable of giving it a *body*, as the workmen call it; and according to the nature of this substance, the colour will be transparent or otherwise. This basis ought to be of the most fixed and durable nature; unalterable by the weather, by acids, or by alkalies. It ought also to be of a pure white colour, and easily reducible into an impalpable powder. For this reason all earthy substances should be avoided as being acted upon by acids; and therefore, if any of these were added to heighten the colour, they would not fail to be destroyed, and their effect totally lost. Precipitates of lead, bismuth, &c. though exceedingly fine and white, ought also to be avoided, as being apt to turn black by exposure. The only substance to be chosen in preference to all others, is calx of tin, prepared either by fire or the nitrous acid. This is so exceedingly refractory as not only to be unalterable by alkalies, acids, or the sun and weather, but even by the focus of a very large burning mirror. It is besides white as snow, and capable of being reduced to an extreme degree of fineness, inasmuch that it is made use of for polishing metalline speculums. For these reasons it is the most proper basis for all fine colours. For coarse ones, the white precipitate of lead, mentioned under the article CHEMISTRY, n° 152, will answer very well. It hath a very strong body, i. e. is very opaque, and will cover well; may be easily ground fine, and is much less apt to turn black than

white-lead; it is besides very cheap, and may be prepared at the small expence of 3 d. per pound.

If what we have just now observed is attended to, the general method of extracting colours from any vegetable or animal substance, and fixing them on a proper basis, must be very easily understood. For this purpose, a quantity of calx of tin is to be procured in proportion to the quantity of colour desired. This must be well rubbed in a glass mortar, with a little of the substance designed for brightening the colour, as alum, cream of tartar, spirit of nitre, &c. after which it must be dried, and left for some time, that the union between the two substances may be as perfect as possible. If the colour is to be a very fine one, suppose from cochineal, the colouring matter must be extracted with spirit of wine without heat. When the spirit is sufficiently impregnated, it is to be poured by little and little upon the calx, rubbing it constantly, in order to distribute the colour equally through all parts of the calx. The spirit soon evaporates, and leaves the calx coloured with the cochineal. More of the tincture is then to be poured on, rubbing the mixture constantly as before; and thus, with proper management, may very beautiful colours, not inferior to the best carmine, be prepared at a moderate expence. If, instead of cochineal, we substitute brazil-wood, turmeric, logwood, &c. different kinds of red, yellow, and purple, will be produced. For the coarser colours, aqueous decoctions are to be used in a similar manner; only as these are much longer of evaporating than the spirit of wine, very little must be poured on at a time, and the colours ought to be made in large quantity, on account of the tediousness of the process.

Hitherto we have considered only the effects of the pure and simple salts, viz. acids and alkalies, on different colours; but by combining the acids with alkalies, earths, or metals, these effects may be varied almost *in infinitum*; neither is there any rule yet laid down by which we can judge *a priori* of the changes of colour that will happen on the admixture of this or that particular salt with any colouring substance. In general, the perfect neutrals act weakly; the imperfect ones, especially those formed from metals, much more powerfully. Alum and sal ammoniac considerably heighten the colour of cochineal, brazil, turmeric, fustic, madder, logwood, &c. The same thing is done, though in a less degree, by common salt, Glauber's salt, salt-petre, and many other neutrals. Solutions of iron in all the acids strike a black with every one of the above mentioned substances; and likewise with sumach, galls, and other astringents. Solutions of lead, or saccharum saturni, universally debase red colours to a dull purple. Solution of copper changes the purple colour of logwood to a pretty good blue; and, in general, solutions of this metal are friendly to blue colours. The effects of solutions of gold, silver, and mercury, are not so well known; they seem to produce dark colours of no great beauty. The most powerful solution, however, with regard to a great number of colours, is that of tin, made in aqua regia. Hence we may see the fallacy of Mr Delaval's hypothesis concerning colours*, that the least refrangible ones are produced

making.

by the most dense metals : for tin, which hath the least density of any metal, hath yet, in a state of solution, the most extraordinary effects upon the least refrangible colours as well as those that are most so. The colour of cochineal is changed by it into the most beautiful scarlet; a similar change is made upon the colouring matter of gum-lac. Brazil-wood is made to yield a fine purplish crimson; logwood, a beautiful dark purple; turmeric, fustic, weld, and all yellow-colouring woods and flowers, are made to communicate colours far more beautiful than can be got from them by any other method. The blue colour of the flowers of violets, eye-bright, iris, &c. are heightened so as to equal, if not excel, the blue produced by a solution of copper in volatile alkali. In short, this solution seems to be of much more extensive use in colour-making, when properly applied, than any thing hitherto thought of. It is not, however, universally serviceable. The colour of madder it totally destroys, and likewise that of safflower, changing them both to a dull orange. It likewise spoils the colour of archil; and what is very remarkable, the fine red colour of tincture of roses made with oil of vitriol, is by solution of tin changed to a dirty green.

The most important consideration in colour-making is to make choice of such materials as produce the most durable colours; and if these can be procured, an ordinary colour from them is to be preferred to a bright one from those which fade sooner. In what the difference consists between the colours that fade, and those which do not, is not known with any degree of certainty. From some appearances it would seem that those substances which are most remarkable for keeping their colour, contain a viscous, glutinous matter so combined with a refinous one as to be soluble both in water and spirit of wine. The most durable red colour is prepared from gum-lac. This is very strongly refinous, though at the same time so far glutinous, that the colouring-matter can be extracted from it by water. Next to gum-lac, are madder roots and cochineal. The madder is an exceedingly penetrating substance, inasmuch, that when given to animals along with their food, it tinges their bones of a deep red colour. Its colouring-matter is soluble both in water and spirit of wine. Along with the pure red, however, there is in madder a kind of viscous, asstringent substance, of a dark brown colour, which seems to give the durability to the whole. The colouring-matter of cochineal, though soluble both in water and spirit of wine, is v. y. tenacious and mucilaginous, in which it bears some resemblance to the *purpura* of the ancients, which kept its colour exceedingly well. Where the colours are fugitive, the tinging substance seems to be too refinous, or too mucilaginous. Thus the colours of brazil, turmeric, &c. are very refinous, especially the latter; inasmuch that the colouring-matter of turmeric can scarcely be extracted by water. Both these are perishable, though beautiful colours; and much more are the red, purple and blue flowers, commonly to be met with. These seem to be entirely mucilaginous without the least quantity of refinous matter. The yellow flowers are different, and in general keep their colour pretty well. Whether it would be possible, by adding occa-

sionally a proper quantity of gum or resin, to make the fugitive colours more durable, hath not yet been tried, but seems to have some probability. What tends a little to confirm this, is a process given by Mr. Hellot for imparting durability to the colour of brazil. It consists only in letting decoctions of the wood stand for some time in wooden casks till they grow stale and rropy. Pieces of woollen cloth now dyed in the liquor acquired a colour so durable, that they were not in the least altered by exposure to the air during four months in the winter season. Whether this change in the durability of the colour was effected by the ropiness following the fermentation, or by some other cause, or whether the experiment can be at all depended upon, must be referred to future observation.

Having thus collected all that can as yet be depended upon for establishing a general theory of colour-making, we shall now proceed to give an account of the different pigments generally to be met with in the colour-shops.

1. *Black*. These are lamp-black, ivory-black, blue-black, and Indian-ink. The first is the finest of what are called the foot-blacks, and is more used than any other. Its preparation is described in the Swedish Transactions for the year 1754, as a process dependent on the making of common resin: the impure refinous juice collected from incisions made in pine and fir trees, is boiled down with a little water, and strained whilst hot through a bag: the dregs and pieces of bark left in the strainer are burnt in a low oven, from which the smoke is conveyed through a long passage into a square chamber, having an opening on the top on which is a large sack made of thin woollen stuff: the foot, or lamp-black, concretes partly in the chamber, from whence it is swept out once in two or three days, and partly in the sack, which is now and then gently struck upon, both for shaking down the foot, and for clearing the interstices betwixt the threads, so as to procure a sufficient draught of air through it. In this manner lamp-black is prepared at the turpentine houses in England, from the dregs and refuse of the refinous matters which are there manufactured.

On this subject, Dr Lewis hath some curious observations. "The foot, (says he,) arising in common chimneys, from the more oily or refinous woods, as the fir and pine, is observed to contain more dissoluble matter than that from the other woods: and this dissoluble matter appears, in the former, to be more of an oily or refinous nature than in the latter; spirit of wine extracting it most powerfully from the one, and water from the other. The oiliness and solubility of the foot seeming, therefore, to depend on those of the subject it is made from, it has been thought that lamp-black must possess these qualities in a greater degree than any kind of common foot. Nevertheless, on examining several parcels of lamp-black, procured from different shops, I could not find that it gave any tincture at all, either to spirit or to water.

"Suspecting some mistake or sophistication, or that the lamp-black had been burnt or charred, as it is to fit it for some particular uses, I prepared myself some foot from linseed oil, by hanging a large copper pan over

making.

over the flame of a lamp to receive its smoke. In this manner the more curious artists prepare lamp-black for the nicer purposes; and from this collection of it from the flame of a lamp, the pigment probably received its name. The foot so prepared gave no tincture either to water or to spirits, any more than the common lamp-black of the shops. I tried different kinds of oily and resinous bodies with the same event; even the soots obtained from fish-oils and tallow did not appear to differ from those of the vegetable-oils and resins. They were all of a finer colour than the lamp-black commonly sold.

"Some foot was collected in like manner from fir and other woods, by burning small pieces of them slowly under a copper-pan. All the soots were of a deeper black colour than those obtained from the same kinds of woods in a common chimney, and very little, if at all, inferior to those of the oils: they gave only a just discernible tincture to water and spirit, while the soots of the chimney imparted a strong deep one to both. The foot of mineral bitumens, in this close way of burning, appears to be of the same qualities with those of woods, oils, and resins: in some parts of Germany, great quantities of good lamp-black are prepared from a kind of pit-coal.

"It appears, therefore, that the differences of soots do not depend altogether on the qualities of the subjects, but in a great measure on the manner in which the subject is burnt, or the foot caught. The soots produced in common chimneys, from different kinds of wood, resinous and not resinous, dry and green, do not differ near so much from one another, as those which are produced from one kind of wood in a common chimney, and in the confined way of burning above-mentioned."

19
Ivory-
black.

Ivory-black is prepared from ivory or bones burnt in a close vessel. This, when finely ground, forms a more beautiful and deeper colour than lamp-black; but in the common methods of manufacturing, it is so much adulterated with charcoal-dust, and so grossly levigated, as to be unfit for use. An opaque deep black for water-colours, is made by grinding ivory-black with gum-water, or with the liquor which settles from the whites of eggs after they have been suffered to stand a little. Some use gum-water and the whites of eggs together, and report, that a small addition of the latter makes the mixture flow more freely from the pencil, and improves its glossiness. It may be observed, however, that though ivory-black makes the deepest colour in water as well as in oil-painting, yet it is not on this account always to be preferred to other black pigments. A deep jet-black colour is seldom wanted in painting; and in the lighter shades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great measure lost.

20
Blue-black.

Blue-black is said to be prepared from the burnt stalks and tendrils of the vine. These, however, the colour-makers seldom give themselves the trouble of procuring, but substitute in its place a mixture of ivory-black and the common blue used for cloaths.

21
Indian-ink.

Indian-ink is an excellent black for water-colours. It hath been discovered by Dr Lewis to consist of a

Colour-
making

mixture of lamp-black and common ghee. Ivory-black, or charcoal, he found to answer equally well, provided they were levigated to a sufficient degree of fineness, which indeed requires no small trouble.

22

White
colours.

2. *White.* The white colours commonly to be met with are, white-flake, white-lead, calcined hartshorn, pearl-white, Spanish-white, egg-shell white, and magistery of bismuth. The flake-white and white-lead are properly the same. The preparation of the former is kept a secret; the method of preparing the latter is described under CHEMISTRY, n° 281. These are the only whites that can be used in oil, all the rest being transparent unless they are laid on with water. Calcined hartshorn is the most useful of the earthy whites, as being the least alkaline. Spanish-white is only finely prepared chalk. Pearl-white is made from oyster-shells; and egg-shell white from the shells of eggs. All these, by their attraction for acids, must necessarily destroy such colours as have any acid or metallic salt in their composition. The magistery of bismuth is apt to turn black, as are also flake-white and white-lead, when used in water. The white precipitate of lead recommended under CHEMISTRY, n° 152, is greatly superior as a water-colour to all these; being perfectly free of any alkaline quality, and not at all apt to lose its own colour, or to injure that of other substances.

23

Red co-
lours.

3. *Red.* The red colours used in painting are of two sorts; viz. those which incline to the purple, and such as are of a full scarlet and tend rather to the orange. The first are carmine, lake, rose-pink, red-ochre, and Venetian-red. The second are vermilion, red-lead, scarlet-ochre, common Indian-red, Spanish-brown, and terra di Sienna, burnt.

We have already laid down some general rules for the preparation of carmine and lake. Particular receipts have been delivered with the greatest confidence for making these fine colours; but all of them must necessarily prove ineffectual, because an earthy basis is recommended for striking the colour upon: from the principles of chemistry, however, we are certain, that if aqua fortis, or solution of tin, is made use of for brightening a colour made with any earthy basis, it must infallibly be destroyed by that basis, by reason of its alkaline quality. Carmine is the brightest and most beautiful red colour known at present; the best comes from France. Lake differs from it in being capable of mixture with oil, which carmine is not, unless with great difficulty. The former is also much more inclined to purple than carmine. This last quality, however, is reckoned a defect; and accordingly, the more that lake approaches to the scarlet or true crimson, the more it is valued. On dropping solution of tin into an aqueous tincture of brazil-wood, a beautiful precipitate falls, of a purplish crimson colour. This may be very well substituted in place of the dearer lakes, on many occasions.

Rose-pink is a very beautiful colour, inclining more to the purple than scarlet. It seems to be made of chalk coloured with a decoction of brazil-wood, heightened by an alkaline salt; for which reason it is exceedingly perishable, and but little esteemed. The colour might be made much more durable as well as better, by employing for a basis the white precipitate of lead above-mentioned,

Colour-
making.

mentioned, and brightening it with solution of tin. Red-ochre and Venetian-red differ in nothing from the colcothar of vitriol well calcined. The calces of iron may be made to appear either purplish, or inclining to the scarlet, according to the manner in which the calcination is performed. If the matter is perfectly deprived of its phlogiston, and subjected to an intense fire, it always turns out red; but the mixture of a small quantity of inflammable matter gives it a purplish cast. Hence various paints are kept in the shops under different names, which yet differ from each other only in the slight circumstance above-mentioned: and such are the scarlet-ochre, Spanish-brown, and terra di Sienna burnt. It is remarkable, that the calces of iron never show their colour till they become cold. Colcothar of vitriol, while hot, always appears of a very dark, dusky purple.

Of the preparation of vermilion and red-lead, an account is given under the article CHEMISTRY, n° 402, 474. These are very durable colours; the first is the best red used in oil-painting, but does not answer well in water: the other is rather an orange; and, like other preparations of lead, is in some cases apt to turn black.

4. *Orange.* The only true orange-colored paints are red-orminet and orange-lake. The first is a sublimate formed of arsenic and sulphur; the other may be prepared from turmeric infused in spirit of wine, having its colour struck upon calx of tin, and brightened by a solution of that metal. All the shades of orange, however, may be extemporaneously prepared by mixing red and yellow colours together in due proportions.

5. *Yellow.* The yellow paints most commonly in use are, king's-yellow, Naples-yellow, Dutch-pink, English-pink, masticot, common orpiment, yellow-ochre, terra di Sienna unburnt, and Turbith-mineral.

King's-yellow is evidently an arsenical preparation. Its colour is exceedingly beautiful, but apt to fade; on which account, and its great price, it is seldom used.

Naples-yellow was for a long time thought to be a preparation of arsenic, but is now discovered to have lead for its basis*. It is therefore apt to turn black and lose its colour, which makes it the less valuable. It is nevertheless used in preference to king's-yellow, on account of its inferiority in price. This colour is particularly liable to be spoiled by iron when moist, and therefore should never be touched by that metal unless previously ground in oil.

Dutch-pink is said to be prepared by striking the colour of yellow berries upon finely levigated chalk. But of this there is great reason to doubt: the basis of Dutch-pink seems much more hard and gritty than chalk, and its colour more durable than those struck upon that earth usually are. Very good yellows may be prepared with the white precipitate of lead formerly mentioned, by using either yellow berries, masticot, or any other substance capable of yielding that colour. English-pink is paler than the Dutch, and keeps its colour greatly worse.

Masticot is prepared by calcining white-lead till it assumes a yellowish colour. It is not apt to change, but the colour is so dull that it is seldom used either in oil or water.

Vol. III.

Colour-
making.

Common orpiment is a pretty bright greenish-yellow, prepared by subliming arsenic with sulphur. Its nauseous smell, which is greatly increased by grinding in oil, makes it very disagreeable; nor does it keep its colour for any length of time. That kind of orpiment least inclined to green is to be preferred for the purposes of painting.

Yellow-ochre and terra di Sienna, are ferruginous earths, capable of becoming red by calcination. Green vitriol precipitated by lime may be advantageously substituted to either of them. See CHEMISTRY, n° 148.

Turbith-mineral is but little used in painting, though its fine yellow colour seems greatly to recommend it. This preparation is also in all probability very durable; and should seem therefore worthy of a preference either to king's, or Naples, yellow. The method of preparing it is described under CHEMISTRY, n° 154.

Gamboge is a paint that can only be used in water, and is the most common yellow made use of for colouring maps, &c. but for this it is not very proper, being neither quite transparent, nor very durable.

6. *Green.* The only simple green colour that hath a tolerable degree of brightness is verdigraese, or preparations of it. This, however, though a very beautiful colour, is far from being durable. It is improved in colour, though not in durability, by dissolution and crystallization in distilled vinegar; in which state it is called *distilled verdigraese*. A more durable water-colour is made by dissolving the verdigraese in cream of tartar, or rather the pure tartarous acid; but in oil this is found to be equally fugitive with the verdigraese itself. For an account of these preparations, see CHEMISTRY, n° 298.

Compound greens are either made of Prussian, or some other blue, mixed with yellow; but in whatever way these colours can be compounded, the beauty of the green produced is greatly inferior to distilled, or even common, verdigraese. The tartarous solution of verdigraese, mixed with a little gamboge, is the best transparent green water-colour we have had an opportunity of trying; and a mixture of Prussian-blue and turbith-mineral is probably the best opaque one.

Sap-green is a simple colour, but exceedingly inferior to distilled verdigraese, or even to the tartarous solution of verdigraese with gamboge. It is prepared from the juice of unripe buckthorn-berries evaporated to the consistence of a gum. Its green-colour is greatly inclined to yellow. A kind of compound green has been sometimes used, called *Prussian-green*, which consists only of Prussian-blue and yellow-ochre. It has no beauty, nor is it durable. It is prepared as Prussian-blue, only not pouring on any spirit of salt to dissolve the ochreous sediment which falls at the same time.

Another green sometimes used is called *terra verte*. This is a native earth, probably impregnated with copper. It is of a bluish green colour, much of that taint called *sea-green*. It is gritty, and therefore must be well levigated before it is used. Its colour is durable, but not very bright.

7. *Blue.* The blue colours are ultramarine, Prussian-blue, verditer, smalt, bice, and indigo. Of these the ultramarine is the finest, but its great price hinders its being much used. It is a preparation from

26
Green colours.

27
Blue colours.

12 I

lapis

Colour-
making

lapis lazuli; is an exceeding bright colour, and never fades with whatever substance it is mixed. It is now, however, in a great measure superseded by Prussian-blue, to the disadvantage of painting in general; as Prussian-blue, though very beautiful, is far from being durable. For an account of its preparation see the article ULTRAMARINE.

The process for making Prussian-blue is described, and its nature fully considered, under CHEMISTRY, n° 287: so that it is sufficient here to observe, that Prussian-blue is to be accounted of the best quality when it is deep, bright, and not inclined to purple. It ought to be tried by mixture with white-lead, as the brightness of the colour will appear much more when diluted than when concentrated in the lumps of the blue itself.

Blue verditer is an exceeding bright blue colour, inclining to green. The method of preparing it is kept a secret *. It is durable in water, but dissolves in oil, and has then all the inconveniences of verdigrise above-mentioned.

Smalt is glass-coloured with zaffre, a preparation from cobalt †. It is commonly so grossly powdered that it cannot be used in painting, and its texture is so hard that it cannot easily be levigated. Its colour is exceedingly bright and durable; so that when finely levigated it is used instead of ultramarine. The most proper materials for levigating this substance seem to be the plates of M. Reamur's porcelain recommended by Dr Lewis. See CHEMISTRY, n° 92, 97. For the preparation and qualities of bice, see the articles LAPIS ARMENUS and BICE.

Indigo is but little used in painting either in oil or water, on account of the dulness of the colour. It requires no other preparation than being washed over. Its goodness is known by the darkness and brightness of the colour. See INDIGO.

8. *Purple*. The only simple colour of this kind used at present is colcothar of vitriol. A beautiful purple lake may be prepared from logwood by means of solution of tin; but this method of preparing colours is very little known as yet.

9. *Brown*. The brown colours are, bistre, brown ochre, Cologne-earth, umbre, and brown pink. Under the article BISTRE is given a process for making that colour, by infusing foot in water, pouring off the tincture, and then evaporating it to an extract; but Dr Lewis is of opinion, with Mr Landois in the French *Encyclopédie*, that the foot is either boiled in water, or ground with a little liquid of some kind into a smooth paste: it is then diluted with more water, and after standing for about half an hour till the grosser substance of the foot has settled, the liquor is poured off into another vessel, and set by for two or three days that the finer parts may fall to the bottom, and this fine matter is the bistre. This is a very useful colour in water, being exceedingly fine, durable, and not apt to spoil any other colours with which it is mixed. The brown pink is said to consist of chalk tinged with the colouring matter of fustic, heightened by fixed alkaline salts. It is therefore very perishable, and is seldom used. The other browns are a kind of ochreous earths; for a description of which see their proper articles.

Having now considered most of the colouring substances usually to be met with in the shops, we shall next take notice of some attempts that have been made to produce all the different colours from vegetables, after the manner of lakes; which, though the methods hitherto tried have for the most part failed of success, may perhaps some time or other be found applicable to valuable purposes.

From infusions of alstringent vegetables mixed with green vitriol, is produced a deep black liquor of very extensive use in dyeing *. The substances which produce the deepest blacks are galls and logwood. When a decoction or infusion of the galls is dropped into a solution of the vitriol largely diluted with water, the first drops produce bluish or purplish red clouds, which soon mingling with the liquor, turn it uniformly of their own colour. It seems to be on the quality of the water that this difference in the colour depends. With distilled water, or the common spring-waters, the mixture is always blue. If we previously dissolve in the water the most minute quantity of any alkaline salt, too small to be discovered by any of the common means by which waters are usually tried, or if the water is in the least putrid, the colour of the mixture proves purple or reddish. Rain-water caught as it falls from the clouds in an open field in clean glass-vessels, gives a blue; but such as is collected from the tops of the houses, grows purple with the mixture of vitriol and galls: from whence it may be presumed, that this last has contracted a putrid tendency, or received an alkaline impregnation, though so slight as not to be sensible on other ways of trial.

Both the purple and blue liquors, on adding more of the alstringent infusion, deepen to a black, more or less intense according to the nature of dilution: if the mixture proves of a deep opaque blackness, it again becomes bluish or purplish when further diluted. If suffered to stand in this diluted state for two or three days, the colouring matter settles to the bottom in form of a fine black mud, which by slightly shaking the vessel, is diffused again through the liquor, and tinges it of its former colour. When the mixture is of a full blackness, this separation does not happen, or in a far less degree; for though a part of the black matter precipitates in standing, yet so much remains dissolved, that the liquor continues black. This suspension of the colouring substance, in the black liquid, may be attributed in part to the gummy matter of the alstringent infusion increasing the consistence of the watery fluid; for the separation is retarded in the diluted mixture, by a small addition of gum Arabic. If the mixture either in its black or diluted state is poured into a filter, the liquor passes through coloured; only a part of the black matter remaining on the filter. The filtered liquor on standing for some time becomes turbid and full of fine black flakes: being freed from these by a second filtration, it again puts on the same appearance; and this repeatedly, till all the colouring parts are separated, and the liquor has become colourless.

Dr Lewis, from whose Philosophical Commerce of Arts this account is taken, further informs us, that this colouring matter, when separated from the liquor and dried, appeared of a deep black, which did not seem

to have suffered any change from the air by exposure for upwards of four months. Made red-hot, it glowed and burnt, but did not flame, and became a rusty brown powder, which was readily attracted by a magnetic bar; though in its black state the magnet had no action upon it. The vitriolic acid, diluted with water and digested on the black powder, dissolved greatest part of it, leaving only a very small quantity of whitish matter. Solution of pure fixed alkaline salt dissolved very little of it: the liquor received a reddish brown colour, and the powder became blackish brown. This residuum was attracted by the magnet after being red-hot, though not before: the alkaline tincture, passed through a filter, and mixed with a solution of green vitriol, struck a deep brownish black colour, nearly the same with that which results from mixing with the vitriolic solution, an alkaline tincture of galls.

33
Black from a combination of other colours.

It hath also been attempted to produce black from a combination of other colours; as green may be produced from a mixture of blue and yellow. Mr le Blon, in his *Harmony of Colours*, gives a method of forming black, by mixing together the three colours called primitive, viz. blue, red, and yellow; and Mr Castet, in his *Optique des Couleurs*, published in 1740, says that this compound black has an advantage, in painting, above the simple ones, of answering better for the darkening of other colours. Thus, if blue, by the addition of black, is to be darkened into the colour called *blue-black*, the simple blacks, according to him, if used in sufficient quantity to produce the requisite deepness, conceal the blue, while the compound blacks leave it distinguishable. Le Blon does not mention the proportions of the three colours necessary for producing black. Castet directs 15 parts of blue; five of red, and three of yellow; but takes notice, that these proportions are rather speculatively than practically just, and that the eye only can be the true judge; our colours being all very imperfect, and our pigments or other bodies of one denomination of colour being very unequal in their degree of intensity. He observes, that the pigments should all be of the deepest and darkest kind; and that, instead of taking one pigment for each colour, it is better to take as many as can be got; for the greater discord there is of heterogeneous and discordant drugs, the more true and beautiful, he says, will the black be, and the more capable of uniting with all other colours, without suppressing them, and even without making them tawney.

Dr Lewis acquaints us, that by mixing different blue, red, and yellow colours, he has not been able to produce a perfect black; but has often obtained from them very dark colours, such as may be called *brown-blacks*, or *grey-blacks*; such as we commonly see in the dark parts of paintings, and such as the charcoal and foot blacks appear when diluted a little. The ingredients being each of a dark deep colour is a very necessary condition; for bright blues, bright reds, and bright yellows, mixed in such proportions that neither colour prevailed, produced only a grey. In effect, all compositions of this kind, physically considered, can be no other than greys, or some of the intermediate tints between whiteness and darkness; and

these greys will be so much the lighter or darker, as the component colours of themselves are bright or dark.

Colour-making.

With regard to the extraction of the colouring matter from the different kinds of vegetables commonly to be met with of all colours, this would certainly be a very valuable acquisition, could the colours so procured be made durable. On this subject nothing hath yet appeared more satisfactory than what is delivered by Dr Lewis in his notes on Neuman's chemistry. His observations are curious, but promise very little success to any who shall attempt to fix these vegetable colours.

"Among the infinite variety of colours, (says he,) which glow in the flowers of plants, there are very few which have any durability, or whose fugitive beauty can be arrested by art, so as to be applied to any valuable purposes. The only permanent ones are the yellow: the red, the blue, and all the intermediate shades of purples, crimsons, violets, &c. are extremely perishable. Many of these flowers lose their colours on being barely dried; especially if they are dried slowly as has been usually directed, in a shady, and not warm place. The colours of all of them perish on keeping even in the closest vessels. The more hastily they are dried, and the more perfectly they are secured from the air, the longer they retain their beauty. The colouring matter extracted and applied on other bodies is still more perishable: oftentimes it is changed or destroyed in the hands of the operator.

"The colour of many blue flowers is extracted by infusion in water; but there are some from which water gains only reddish, or purplish blue. Of those that have been tried there is not one which gives any blue tincture to spirituous liquors: some give no colour at all, and some a reddish one. The juice pressed out from the fresh flowers is for the most part blue. The blue juices and infusions are changed red by all acids. The marine acid seems to strike the most florid red. The flowers themselves macerated in acid liquors, impart also a deep red tincture. Alkalies, both fixed and volatile, and lime-water, change them to a green. Those infusions of the juices, which have nothing of the native colour of the flowers, suffer the same changes from the addition of acid and alkaline liquors: even when the flowers have been kept till their colour is lost, infusions made from them acquire still a red colour from the one, and a green from the other, though in a less degree than when the flowers were fresh. The red colour produced by acids is scarcely more durable than the original blue: applied upon other bodies and exposed to the air, it gradually degenerates into a faint purplish, and at length disappears, leaving hardly any stain behind. The green produced by alkalies changes to a yellow, which does not fade so soon. The green, by lime-water, is more permanent and more beautiful: green lakes, prepared from these flowers by lime-water, have been used as pigments by the painter. The flowers of cyanus have been greatly recommended, as affording elegant and durable blue pigments; but I have never been able to extract from them any blue colour at all. They retain their colour indeed, when hastily dried, longer than some other blue flowers: but they com-

34
Dr Lewis's experiments on vegetable colours.

Colour-
making.

communicate nothing of it to any kind of menstruum. Infusions of them in watery, spirituous, and oily liquors, are all of them more or less of a reddish cast, without any tendency to blue. Alum, which is said to heighten and preserve their blue colour, changes it, like that of other blue flowers, to a purplish red; acids to a deep red: alkalies and lime-water to a green: solution of tin added to the watery infusion, turns it of a fine crimson: on standing, a beautiful red *fecula* subsides, but it loses all its colour by the time it is dry. The watery infusion, inspissated to the consistence of an extract, appears of a dark reddish brown: an extract made with rectified spirit is of a purplish colour. The colour of both extracts spread thin and exposed to the air quickly fades. The flowers employed in these experiments were those of the common blue-bottle of the corn-fields.

“Red flowers readily communicate their own red colour to watery menstrua: among those that have been tried, there is not one exception. Those of a full red colour give to rectified spirit also a deep red tincture, brighter, though somewhat paler than the watery infusion: but the lighter red flowers, and those which have a tendency to purplish, impart very little colour to spirit, and seem to partake more of the nature of the blue flowers than of the pure red. Infusions of red flowers are supposed to be heightened by acids, and turned green by alkalies, like those of the blue; but this is far from being universal. Among those I have examined, the rose-colours and purplish reds were changed nearly in the same manner as the blues; but the full deep reds were not. The deep infusion of red poppies is changed by alkalies, not to a green, but to a dusky purple.

“The colours of yellow flowers, whether pale or deep, are in general durable. Many of them are as much so, perhaps, as any of the native colours of vegetables. The colour is extracted both by water and by spirit. The watery infusions are the deepest. Neither alkalies nor acids alter the species of the colour, though both of them vary its shade; acids rendering it paler, and alkalies deeper: alum likewise considerably heightens it, though not so much as alkalies. An infusion of the flowers, made in alkaline ley, precipitated by alum, gives a durable yellow lake. In some of the deep reddish yellow, or orange-coloured flowers, the yellow matter seems to be of the same kind with that of the pure yellow flowers, but the red to be of a different kind from the pure red ones; watery menstrua take up only the yellow, and leave the red, which may afterwards be extracted by rectified spirit of wine, or by water acuated by fixed alkaline salt. Such particularly are the saffron-coloured flowers of *carthamus*. These, after the yellow matter has been extracted by water, are said to give a red tincture to ley; from which on standing at rest for some time, a deep bright red *fecula* subsides; called for one of the names of the plant which produces it, *safflower*; and from the countries whence it is commonly brought to us, *Spanish-red*, and *China-lake*. This pigment impregnates spirit of wine with a beautiful red tincture, but communicates no colour to water. I have endeavoured to separate by the same treatment, the red matter of some of the other reddish yellow flowers,

as those of garden marigold, but without success. Plain water extracted a yellow colour, and alkaline ley extracted afterwards only a paler yellow: though the digestions were continued till the flowers had lost their colour, the tinctures were no other than yellow, and not so deep as those obtained from the pure yellow flowers. The little yellow *stoculi*, which in some kinds of flowers, are collected into a compact round disc, as in the daisy and corn-marigold, agree so far as they have been examined, with the expanded yellow petals. Their colour is affected in the same manner by acids, by alkalies, and by alum; and equally extracted by water and by spirit. But the yellow farina, or fine dust, lodged on the tips of the stamina of flowers, appears to be of a different kind. It gives a fine bright yellow to spirit, and a duller yellow to water; the undissolved part proving in both cases of a pale yellowish white. Both the watery and spirituous tinctures were heightened by alkaline liquors, turned red by acids, and again to a deep yellow on adding more of the alkali: I know no other vegetable yellow that is turned red by acids.

“White flowers are by no means destitute of colouring matter. Alkaline lixivia extract from some of them a green tincture, and change their colourless expressed juices to the same colour; but I have not observed, that they are turned red by acids. The flowers of the common wild convolvulus or bind-weed, which in all their parts are white, give a deep yellow or orange tincture to plain water; which, like the tinctures of flowers that are naturally of that colour, is rendered paler by acids, heightened a little by alum, and more considerably by alkaline salts. The vapours of the volatile vitriolic acid, or of burning sulphur, which whiten or destroy the colour of the coloured flowers, make no change in the white.

“The red juices of fruits, as currants, mulberries, elder-berries, morello and black cherries, &c. gently inspissated to dryness, dissolve again almost totally in water, and appear nearly of the same red colour as at first. Rectified spirit extracts the tingling particles, leaving a considerable portion of mucilaginous matter undissolved; and hence the spirituous tincture proves of a brighter colour than the watery. The red solutions, and the juices themselves, are sometimes made dull and sometimes more florid, by acids, and generally turned purplish by alkalies. The colours of these juices are for the most part perishable. They resist, indeed, the power of fermentation, and continue almost unchanged, after the liquor has been converted into wine, but when the juice is spread thin upon other bodies, exsiccated, and exposed to the air, the colour quickly alters and decays: the bright lively red change the soonest: the dark dull red stain from the juice of the black cherry, is of considerable durability. The fruit of the American *opuntia* or prickly pear, the plant upon which the cochineal insect is produced, is perhaps an exception: This bright red fruit, according to Labat, gives a beautiful red dye. Some experiments, however, made upon the juice of that fruit, as brought into England, did not promise to be of any great advantage: but the particulars I cannot now recollect.

“The ripe berries of buckthorn stain paper of a green

Colour-
making.35

from fruits.

Colour-
making.

green colour. From these is prepared the substance called *sap-green*, a pigment sufficiently durable, readily soluble in water, but not miscible with oil. The berries dried while green, and macerated in alum-water, are said to yield a yellow pigment; and when they have grown over ripe so as to fall off spontaneously, a purple one. It is said that the berry of the *heliotropium tricoctum*, which grows wild about Montpellier, stains paper of a green colour, and that this green turns presently to a blue: that the common blue paper receives its colour from this juice: and that the red rags called *turnsol*, employed for colouring wines and other liquors, are tintured by the same juice turned red by acids. According to M. Nisolle of the French academy of sciences (as quoted by Savary in his *Dictionnaire de Commerce*), the colouring juice is obtained, not from the berries, but from tops of the plant gathered in August, ground in mills, and then committed to the press. The juice is exposed to the sun about an hour, the rags dip in it, dried in the sun, moistened by the vapour which arises during the flaking of quicklime with urine, then dried again in the sun, and dipped again in the juice. The Dutch and others are said to prepare *turnsol* rags, and *turnsol* in the mals, from different ingredients, among which archil is a principal one.

"In some plants, peony for instance, the seeds at a certain point of maturity are covered with a fine shining red membrane. The pellicles of the seeds of a certain American tree afford the red masses brought into Europe under the names of *annatto*, *orlean*, and *roucou* *. Mr Pott, in the Berlin Memoirs for the year 1752, mentions a very extraordinary property of this concrete. 'With the vitriolic acid it produces a blue colour, of extreme beauty; but with this capital defect, that all salts and liquors, and even common water, destroy it.' The specimen of *annatto*, which I examined, was not sensibly acted upon by spirit of vitriol; it received no change in its own colour, and communicated none to the liquor. Nor did any visible change ensue upon dropping the acid into tinctures of *annatto* made in water, or in spirit.

"The green colour of the leaves of plants is extracted by rectified spirit of wine and by oils. The spirituous tinctures are generally of a fine deep green, even when the leaves themselves are dull-coloured, or yellowish, or hoary. The colour, however, seldom abides long even in the liquor; much less when the tinging matter is separated in a solid form, and exposed with a large surface to the air. The editor of the Wirtemberg Pharmacopœia observes, that the leaves of *acanthus*, *brankurine*, or *bear's-breach*, give a more durable green tincture to spirit than those of any other herb. Alkalies heighten the colour both of the tinctures and green juices; acids weaken, destroy, or change it to a brownish: lime-water improves both the colour and durability: by means of lime, not inelegant green lakes are procurable from the leaves of *acanthus*, lily of the valley, and several other plants. There are very few herbs which communicate any share of their green colour to water; perhaps none that give a green of any considerable deepness. It is said, however, that the leaves of some plants give a green dye to woolen, without the

addition of any other colouring matter; particularly those of the wild chervil, or cow-weed, the common ragwort, and devil's-bit. The leaves of many kinds of herbs and trees give a yellow dye to wool or woolen cloth that has been previously boiled with a solution of alum and tartar. Weld, in particular, affords a fine yellow, and is commonly made use of for this purpose by the dyers, and cultivated in large quantity in some parts of England. There is no colour for which we have such plenty of materials as for yellow. Mr Hellot observes, that all leaves, barks and roots, which on being chewed, discover a slight astringency, as the leaves of the almond, peach, and pear-trees, ash-bark, (especially that taken off after the first rising of the sap in the spring), the roots of wild patience, &c. yield durable yellows, more or less beautiful according to the length of time that the boiling is continued, and the proportions of alum and tartar in the preparatory liquor; that a large quantity of alum makes these yellows approach to the elegant yellow of weld; that if the tartar is made to prevail, it inclines then to an orange: that if the roots, barks, or leaves, be too long boiled, the yellow proves tarnished, and acquires shades of brown." See the article DYEING.

The most capital preparations from the leaves of plants, are those of indigo and weld; which are both very much used in dyeing, though the first only in painting *. Both the indigo and woad plants give out their colour, by proper management, to water, in form of a blue fecula or lake. Mr Hellot suspects that a like blue fecula is procurable from many other vegetables. Blue and yellow blended together, compose a green. He supposes the natural greens in vegetables to be compounded in like manner of these two colours; and that the blue is oftentimes the most permanent, so as to remain entire after the putrefaction or destruction of the yellow. The theory is specious, and perhaps just: we know of no other that accounts in any degree for the production of the indigo and woad blue. Dr Lewis, however, informs us, that he never was able to produce the least appearance of either blue or yellow from any of the plants he tried by treating them in the manner used for the preparation of indigo.

There are sundry mosses, which in their natural state, like the indigo and woad plants, promise nothing of the elegant colours that can be extracted from them by art. The most remarkable of these is *archil*, for the preparation of which, and the colours that may be produced from it, see the article. Linnæus suspects that there are several other more common mosses from which valuable colours might be extracted: a quantity of sea-moss, having rotted in heaps on the shore, he observed the liquor in the heaps to be as red as blood; the sea-water, the sun, and the putrefaction, having brought out the colour. Mr Kalm, in an appendix to Linnæus's paper in 1745, mentions two sorts of mosses actually employed in Sweden for dyeing woolen red: one is the *Lichenoides coralliforme apicibus coccineis* of Ray's Synopsis; the other the *Lichenoides tartareum*, *farinaceum*, *scutellarium umbone fusco*, of Dillenius. This last is a white substance like meal clotted together, found on the sides

and tops of hills. It is shaved off from the rocks after rain, purified from the stony matters intermixed among it by washing with water, then dried in the sun, ground in mills, and again washed and dried: it is then put into a vessel with urine, and set by for a month: a little of this tincture added to boiling water makes the dyeing liquor. In the same transactions for the year 1754, there is an account of another moss, which, prepared with urine, gives a beautiful and durable red or violet dye to wool and silk. This is the lichen foliaceus umbilicatus fustus lacunensis, Linn. flor. Suec. It grows upon rocks, and is readily distinguishable from others of that class, by looking as if burnt, or parched, consisting of leaves as thin as paper, convex all over on the upper side, with corresponding cavities underneath, adhering firmly to the stones by a little root under the leaves, and coming asunder, when dry, as soon as touched. It is gathered after rain, as it then holds best together, and parts easiest from the stone. In France, a crustaceous moss, growing upon rocks in Auvergne, is prepared with lime and urine, and employed by the dyers as a fucedaneum for the Canary archil, to which it is said to be very little inferior. Mr Hellot relates, that he has met with several other mosses, which, on being prepared in the same manner, acquire the same colour. The most expeditious way, he says, of trying whether a moss will yield an archil or not, is to moisten a little of it with a mixture of equal parts of spirit of salt ammoniac and strong lime-water, and add a small proportion of crude sal ammoniac. The glass is then to be tied over with a piece of bladder, and set by for three or four days. If the moss is of the proper kind, the little liquor which runs from it upon inclining the vessel, will appear of a deep crimson colour; and this afterwards evaporating, the plant itself acquires the same colour. Dr Lewis informs us that he has tried a good number of the common mosses, many both of the crustaceous and foliaceous kind, and not a few of the fungi; as also the herbs chamomile and milfoil, which yield a blue essential oil; and thyme, whose oil becomes blue by digestion with volatile spirits; but never met with any that yielded a colour like archil. Most of them gave a yellow or reddish brown tincture. A few gave a deep red colour to the liquor: but, when diluted, it shewed a yellowish cast, and when applied on cloth it gave only a yellowish red.

38
Some blue
flowers may
probably
yield per-
manent co-
lours.

To these observations we shall only add, that though, in general, the blue colours of flowers are exceedingly perishable, there seem to be at least two exceptions to this rule; for the blue flowers of iris, or flower-de-luce, and those of columbine, when treated with solution of tin yielded a colour tolerably permanent. Indeed, when experiments are made with a view to extract the colour from any part of a vegetable, it will always be proper to try whether it can bear a mixture with this solution. If the colour is not destroyed by it, there is a very great probability that the solution will, by proper management, preserve, and give a durability to it, which could scarce be obtained by any other method. It must, however, be observed, that there are several substances used in colour-making, which solution of tin cannot bear to be mixed

with. These are principally fugar of lead and cream of tartar, as well as all the calcareous earths and alkaline salts. With alum it may be mixed very safely, and is in many cases the better for it. The roots of plants, however, seem to promise more durability of colour than the upper parts. We have seen a blue colour of considerable durability and brightness prepared from the roots of common radishes by expressing the juice, combining it with tobacco-pipe clay, and brightening it with a little alum. The root of the red beet is also said to yield a durable colour of a beautiful red, inclining to scarlet; but this we cannot affirm from our own experience.

40
Colours
for maps.

With regard to liquid colours for maps, &c. we apprehend there can be very little difficulty of preparing all the possible varieties of them, if what we have above laid down is attended to. The only colour with which there can be any difficulty is blue; but the common solutions of indigo in alkalies or acids may be made to answer this purpose, though, on account of their strongly saline quality, they are not very proper. A very curious method of procuring a beautiful transparent blue colour is by extracting the colouring matter from Prussian blue, by means of a caustic alkali. This when laid upon paper appears of a dirty brown colour; but if washed over with a weak solution of green vitriol, is instantly changed to a most beautiful blue. This seems to afford a method of procuring blue transparent colours of greater beauty than they are usually met with.—See specimens of transparent colours prepared according to the above rules, on the Chart (subjoined) to HISTORY.

COLOURING of Porcelain. See PORCELAIN.

COLT, in zoology, a general name for the young of the horse-kind: the male being likewise, for distinction's sake, called a *horse-colt*; the female, a *filly*.

After the colts have been foaled, you may suffer them to run with the mare till about Michaelmas, sooner or later, according as the cold weather comes in; then they must be weaned; though some persons are for having them weaned after Martinmas, or the middle of November. The author of the *Complete Horseman* is of opinion, that the reason why most foals advance so slowly, and are not capable of service till they are six or seven years old, is because they have not sucked long enough; whereas, if they had sucked the whole winter over, they would be as good at four or five years old, as they are now at eight.

They ought now to be kept in a convenient house, with a low rack and manger for their hay and oats, which must be sweet and good; with a little wheaten bran mixed with the oats to cause them to drink, and to keep their bodies open. But, since there are some who allege that oats make foals become blind, or their teeth crooked: the same author is of opinion, that oats will wear their teeth, and make them the sooner to change, and also to raze; therefore he judges it to be the best way to break them in a mill, because that by endeavouring with their jaws to bruise

and

Colt.

and chew them, they stretch and swell their eye and nether-jaw veins, which so attract the blood and humours that they fall down upon the eyes, and frequently occasion the loss of them: so that it is not the heating quality of the oats, but the difficulty in chewing, that is the cause of their blindness.

Further, colts thus fed with grain do not grow thickish upon their legs, but grow broader and better knit than if they had eaten nothing but hay and bran, and will endure fatigue the better. But above all they must be kept from wet and cold, which are hurtful to them, nothing being more tender than they are. For proof of this, take a Spanish Stallion, and let him cover two mares, which for age, beauty, and comeliness may admit of no difference between them; and if they produce both horse-colts, or both fillies, which is one and the same thing, let one run abroad, and the other be housed every winter, kept warm, and ordinarily attended; and that colt that has been kept abroad shall have large fleshy shoulders, flabby and gouty legs, weak pasterns, and ill hoofs; and shall be a dull heavy jade, in comparison to the other which is housed, and orderly kept; and which will have a fine forehead, be fine shaped, and have good legs and hoofs, and be of good strength and spirit: by which you may know, that to have the finest stallion, and the beautifullest mare, is nothing if they are spoiled in the breeding up. It is worth observation, that some foals, under six months old, though their dams yield plenty of milk, yet decay daily, and have a cough, proceeding from certain pellicles or skins that breed in their stomachs, which obstruct their breathing, and at last destroy them entirely. To remedy this malady, take the bag wherein the colt was foaled, dry it, and give him as much of it in milk as you can take up with three fingers: but if you have not preserved the bag, procure the lungs of a young fox, and use it instead of the aforesaid powder.

It will be proper to let the colts play an hour or two in some court-yard, &c. when it is fair weather, provided you put them up again carefully, and see that they take no harm. When the winter is spent, turn them into some dry ground, where the grass is short and sweet, and where there is good water, that they may drink at pleasure: for it is not necessary that a colt should fill his belly immediately, like a horse that labours hard. The next winter you may take them into the house, and use them just as you do your other horses; but let not your horse-colts and fillies be kept together after the first year. This method may be observed every summer and winter till you break them, which you may do after they have been three years old; and it will be a very easy thing if you observe the aforesaid method of housing them: for ordering them the second year as you do your other horses, they will be so tame and gentle, that you need not fear their leaping, plunging, kicking, or the like; for they will take the saddle quietly. As for all those ridiculous methods of beating and cowing them, they are in effect spoiling them, whatever they call it, in ploughed fields, deep ways, or the like; instead of which, let the rider strive to win them by gentle usage, never correcting them but when it is necessary, and then with judgment and moderation.

Colt.

You will not need a cavesson of cord, which is a head strain, nor a pad of straw; but only a common saddle, and a common cavesson on his nose, such as other horses are ridden with; but it ought to be well lined with double leather; and if you please you may put on his mouth a watering bit, but without reins, only the head-stall, and this but for a few days; and then put on such a bit as he should be always ridden with: and be sure not to use spurs for some time after backing. Take notice, that as yearlings must be kept a-broad together, so those of two years old together; the like for those of three yearlings, which ordering is most agreeable to them.

In order to make him endure the saddle the better, the way to make it familiar to him will be by clapping the saddle with your hand as it stands upon his back, by striking it, and swaying upon it, dangling the stirrups by his sides, rubbing them against his sides, and making much of him, and bringing him to be familiar with all things about him; as straining the crupper, fastening and loosening the girths, and taking up and letting out the stirrups. Then as to the motion of him, when he will trot with the saddle obediently, you may walk a trench of a full mouth, and put the same into his mouth, throwing the reins over the forepart of the saddle, so that he may have a full feeling of it; then put on a martingale, buckled at such a length that he may but just feel it when he jerks up his head; then take a broad piece of leather, and put it about his neck, and make the ends of it fast by plating of it, or some other way, at the withers, and the middle part before his weald, about two handbuls below the thropple, betwixt the leather and his neck; let the martingale pass so, that when at any time he offers to duck, or throw down his head, the cavesson being placed upon the tender gristle of his nose, may correct and punish him; which will make him bring his head to, and form him to an absolute rein: trot him abroad, and if you find the reins or martingale grow slack, straiten them, for when there is no feeling there is no virtue.

Colt-Evil, among farriers. See **FARRIERY**, § xxviii. 4.

Colt-Taming, is the breaking of a colt so as to endure a rider. Colts are most easily broke at three or four years of age; but he who will have patience to see his horse at full five, will have him much more free of diseases and infirmities than if he was broke sooner.

Preparatory to their breaking for the saddle, they should be used to familiar actions, as rubbing, clawing, haltering, leading to water, taking up their feet, knocking their hoofs, &c. In order to bridle and saddle a colt, when he is made a little gentle, take a sweet watering trench, washed and anointed with honey and salt, which put into his mouth, and so place it that it may hang about his ruff; then offer him the saddle, but take care not to fright him with it. Suffer him to smell at it, to be rubbed with it, and then to feel it; after that, fix it and gird it fast; and make that motion the most familiar to him to which he seems most averse. Being thus saddled and bridled, lead him out to water and bring him in again: when he has stood reined upon the trench an hour or more, take

take off the bridle and saddle, and let him go to his meat till the evening, and then lead him out as before : and when you carry him in again to set him up, take off his saddle gently, clothing him for all the night.

COLTIE, a term used by timber-merchants, for a defect or blemish in some of the annular circles of a tree, whereby its value is much diminished.

COLUBER, in zoology, a genus of serpents belonging to the order of amphibia. The characters are these : they have a number of scuta, or hard crusts on the belly ; and scutellæ, or scales on the tail. Linnæus enumerates no less than 97 species under this name, distinguished solely by the number of scuta and scutellæ. The most remarkable are the following.

1. The *Vipera*, or common viper of the shops, has 118 scuta, and only 22 scutellæ. The body is very short, and of a pale colour, with brownish spots ; and the head is gibbous, and covered with small scales. It is a native of Egypt, and other warm countries. It has always been remarkable for its poisonous nature ; inasmuch that vipers, when numerous, have often been thought the ministers of divine vengeance, like the plague, famine, and other national calamities. A notion also prevailed among the ancients, that few or none of the parts of a viper were free from poison ; for which reason they made no experiments or discoveries concerning the nature of these creatures. It is now, however, proved, by undoubted experiments, that the poison of vipers, as well as of all other serpents whose bite is hurtful, lies in a bag at the bottom of their two greater teeth or fangs. These teeth are perforated ; and when the creature bites, the compression of the bag forces out a little drop of the poison into the wound, where it produces its mischievous effects. Dr Mead has given a curious anatomical dissertation on those parts of a viper which have any connection with its poison, by which the truth of the above mentioned position is ascertained beyond a doubt. With regard to the poison itself, Dr Mead says its quantity is so inconsiderable, that one good drop does all the execution. When viewed through a microscope, the liquor had a saline appearance. At first he perceived only a quantity of minute salts nimbly floating here and there : but in a very short time the appearance was changed ; and these saline particles were now shot out into crystals of extreme tenuity and sharpness, with something like knots here and there, from whence they seemed to proceed : so that the whole texture did, in some measure, resemble a spider's web, though infinitely finer. He made various experiments in order to determine the quality and species of these crystals, but without effect. Half an ounce of human blood, newly drawn, was not visibly altered, either in colour or consistence, by a mixture with the poison. It then was, and remained, undistinguishable from the same blood taken into another glass in which there was no poison. These portions of blood were severally mixed with acids and alkalis : the envenomed blood was, after such mixtures, of the same colour and consistence with the other. Spirit of nitre, spirit of salt, and juice of lemons, severally poured upon the sanies itself, produced neither fermentation, nor any change of colour.

Oleum tartari per deliquium, and the simple spirit of hartshorn, dropped upon the poison, neither altered its colour, nor raised any ebullition. Syrup of violets mixed with the poison did not change its colour either to red or green. The tincture of heliotropium, that is blue paper, was not altered by the sanies ejected upon it : and this drying still retained its yellowish colour. These experiments were tried by Dr Mead, in presence of a number of gentlemen. They ended their inquiries by tasting the poisonous liquor. Having diluted it with a little warm water, several of them ventured to touch it with the tip of their tongues. They all agreed that it tasted very sharp and fiery, as if the tongue had been struck through with something scalding or burning. This sensation went not off in two or three hours ; and one gentleman who would not be satisfied without trying a large drop undiluted, found his tongue swelled with a little inflammation, and the soreness lasted two days ; but without any farther inconvenience. The purpose answered by this poisonous liquor to the creatures themselves, is probably the destruction of their prey ; for as serpents frequently feed upon animals of very considerable magnitude and strength, they would often undoubtedly make their escape, did not the poisonous juice instilled into the wounds made by the serpent's teeth almost instantly deprive them of life, or at least of all power to struggle with their enemy. For an account of the symptoms produced by the bites of vipers and other venomous serpents in the human body, together with the best methods of cure, see the *Index* subjoined to *MEDICINE*. After the viper is deprived of these bags which contain its poison, it is entirely harmless : nay the flesh of it is highly nutritive, and justly esteemed a great restorative. It hath been much recommended in scrophulous, leprosy, and other obstinate chronic disorders ; but, to answer any good purpose, it must undoubtedly be used for a considerable time as food. The dried flesh which comes to this country from abroad, is justly esteemed by Dr Lewis to be totally insignificant. A volatile salt was formerly drawn from vipers, and sold at a great price, as a sovereign remedy against the bites of vipers and other poisonous animals ; but it is now found not to be materially different from the volatile alkaline salts procured by distilling other animal substances.

2. The *berus*, or common British viper, is found in many countries of Europe. They swarm in the *Hebrides*, or western British isles, and abound in many parts of Britain ; particularly in the dry, stony, and chalky counties. According to Mr Pennant and other naturalists, they are viviparous, but proceed from an internal egg ; being of that class of animals of whose generation Aristotle says, " They conceive a perfect egg within, but bring forth their young alive." This species is far from being prolific ; 11 eggs being the utmost that were ever heard of in one viper. These eggs are, as it were, chained together ; and each about the size of the egg of a black-bird. This viper seldom grows longer than two feet ; though Mr Pennant tells us he once saw a female (which is nearly a third larger than the male) almost three feet long. The ground colour of this serpent is of a dirty yellow, that of the female deeper. Its back is marked the

whole

Coluber.

whole length with a series of rhomboidal black spots, touching each other at the points; the sides with triangular ones; the belly entirely black. It hath 146 scuta, and 39 scutellæ. There is a variety wholly black; but the rhomboid marks are very conspicuous even in this, being of a deeper and more glossy hue than the rest. The head of the viper, says Mr Pennant, is inflated, which distinguishes it from the common snake. Mr Catelby assures us, that the difference between the vipers and other serpents is, that "the former have long hollow fangs, or tusks, with an opening near the point; the neck is small, the head broad, the cheeks extending wide, scales rough, the body for the most part flat and thick; they are slow of motion; swell the head and neck when irritated, and have a terrible and ugly aspect." The tongue is forked, the teeth small; the four canine teeth are placed two on each side the upper jaw: these instruments of poison are long, crooked, and moveable; capable, like those of the former species, of being raised or depressed at the pleasure of the animal, and they infill their poison in the same manner. The vipers are said not to arrive at their full growth till they are six or seven years old; but they are capable of engendering at two or three. They copulate in May, and go about three months with their young. Mr Pennant tells us, that he has been assured of a fact mentioned by Sir Thomas Brown*, who was far from being a credulous writer, that the young of the viper, when terrified, will run down the throat of the parent, and seek for shelter in its belly, in the same manner as the young of the opossum retire into the ventral pouch of the old one. From this some have imagined that the viper is so unnatural as to devour its own young; but this assertion deserves no credit; it being well known that the food of these serpents is frogs, toads, lizards, mice, and, according to Dr Mead, even an animal so large as a mole. These they swallow entire; which, if we consider the narrowness of their neck, shews it capable of a distension hardly credible, had we not ocular proofs of the fact. It is also said, from good authority, that they will prey on young birds; but whether on such as nestle on the ground, or whether they climb up trees for them, as the Indian serpents do, is quite uncertain: the fact, however, is very far from being recent; for Horace tells us,

*Ut affdens impluvibus pullis avis
Serpentum allapsis timet.* EPOD. I.

Thus for its young the anxious bird

The gliding serpent fears.

The viper is capable of supporting very long abstinence; it being known, that some have been kept in a box six months without food, and yet did not abate of their vivacity. They feed only a small part of the year, but never during their confinement; for if mice, their favourite diet, should at that time be thrown into their box, though they will kill, yet they never will eat them. The violence of their poison decreases in proportion to the length of their confinement, as does also the virtue of their flesh whatever it is. The animals, when at liberty, remain torpid throughout the winter; but, when confined, have never been observed to take their annual repose. The method of catching them is by putting a cleft stick on

VOL. III.

or near their head; after which they are seized by the tail, and instantly put into a bag. The viper-catchers are very frequently bit by them in the pursuit of their business, yet we very rarely hear of their bite being fatal. Salad oil, if applied in time, is said to be a certain remedy*. The flesh of the British viper has been celebrated as a restorative, as well as that of the foreign kind. Mr Keyler relates, that Sir Kenelm Digby used to feed his wife, who was a most beautiful woman, with capons fattened with the flesh of vipers.

3. The punctatus of Linnæus, by Mr Catelby called the *water-viper*, is a native of Carolina. According to Linnæus it is ash-coloured, variegated with yellow spots. Mr Catelby informs us, that the head and back of this serpent are brown; the belly marked transversely with yellow, and also the sides of the neck. The neck is small, the head large, and the mouth armed with the destructive fangs of the viper or rattle-snake, next to which it is reckoned the largest serpent in this country. Contrary to what is observed in most other vipers, these are very nimble and active, and very dextrous in catching fish. In summer, great numbers are seen lying on the branches of trees hanging over rivers; from which, on the approach of a boat, they drop into the water, and often into the boat on the mens heads. They lie in wait in this manner to surprise either birds or fish: after the latter they plunge with surprising swiftness, and catch some of a large size, which they bring ashore and swallow whole. The tail of this animal is small towards the end, and terminates in a blunt horny point about half an inch long. This harmless little horn hath been the occasion of many terrible reports; as, that by a jerk of its tail, the animal is capable of instantly destroying both men and beasts; that a tree struck with this terrible horn, in a short time grows black, withers, and dies, &c. but all these Mr Catelby assures us have not the least foundation in fact.

4. The chersea is a native of Sweden, where it is called *asping*. It is a small reddish serpent, whose bite is said to be mortal. Concerning this species Mr Pennant asks, "Is it possible that this could be the species which has hitherto escaped the notice of our naturalists? I rather suspect it, as I have been informed that there is a small snake that lurks in the low grounds of Galloway, which bites and often proves fatal to the inhabitants."

5. The prester of Linnæus, or black viper of Mr Catelby, is a native of Carolina and Virginia. It is short and thick, slow of motion, spreads its head surprisingly when irritated, very flat and head, threatening with a horrid hiss. They are very poisonous; their bite being as deadly as that of the rattle-snake. They frequent the higher lands, and are of a rusty black colour.

6. The coluber luridus of Forster, called by Mr Catelby the *brown viper*; is a native of the same countries with the preceding. It is about two feet long, and large in proportion; very slow in its motion, even when threatened with danger: notwithstanding which, it defends itself very fiercely when attacked, and its bite is as venomous as any. They prey upon eels, lizards, and other animals of that kind.

Coluber.

* *Vulgar Errors*, p. 114.

Coluber.

Besides these species of which we have a particular description, the following are also reckoned among the poisonous serpents, viz. 7. The atropus, with 131 scuta and 22 scutellæ. It is a native of America, the body white, and the eyes brown, with a white iris. 8. The leberis, with 110 scuta and 50 scutellæ, is a native of Canada, and has many black linear rings. 9. The ammodites, with 142 scuta and 32 scutellæ, is a native of the East. It is about six inches long, and has a fleshy protuberance on its nose. 10. The aspis, with 146 scuta and 46 scutellæ, is a native of France; and is of a reddish colour, with dusky spots on the back. 11. The lebetinus, with 155 scuta and 46 scutellæ, is a native of Asia, and is of a cloudy colour, with red spots on the belly. 12. The feverus, with 170 scuta and 42 scutellæ, is likewise a native of Asia, and is ash-coloured with white belts. 13. The stolaus, with 143 scuta and 76 scutellæ, is a native of Asia; and is of a greyish colour, with two white filets. 14. The lacteus, with 203 scuta and 22 scutellæ, is a native of the Indies. Its colour is white, with black spots. 15. The naja, with 193 scuta and 60 scutellæ, is a native of the East Indies, and is reckoned the most poisonous of all serpents. It is killed by the ichneumon. 16. The atrox, with 196 scuta and 69 scutellæ, is a native of Asia. It is of a hoary colour, and the head is compressed and covered with small scales. 17. The nivens, with 209 scuta and 62 scutellæ, is a native of Africa. It is white, and without any spots. 18. The corallinus, with 193 scuta and 82 scutellæ, is a native of Asia. It is greyish, with three brown filets. 19. The diplas, with 152 scuta and 135 scutellæ, is a native of America. It is of a bluish colour, with the margins of the scales white. 20. The mycterizans, with 192 scuta and 167 scutellæ, is a native of America. It hath a stretched out triangular snout.

The above 20 species are all the serpents of the genus of coluber that are reckoned poisonous. Of the rest we shall only mention the following, which are the most remarkable.

21. The erythrogaster of Forster, called by Mr Catesby the *copper-bellied snake*, is a native of Carolina, and grows sometimes near to the size of a rattlesnake. It is of a brown colour in all parts of its body, except the belly which is of a red copper colour. They frequent water, and probably prey on fish; but they will also devour birds and such other animals as they are able to overcome. They are bold and active, frequently entering poultry-houses, devouring the fowls and sucking their eggs.

22. The constrictor, or black snake, is a native of several parts of America. They are very long, sometimes measuring six feet, and are all over of a shining black. They are the most numerous of all; and are very bold and furious, leaping at and biting those that attack them. It is commonly said, that they will attack and devour rattlesnakes. This Mr Catesby says he cannot affirm as truth from his own experience; but assures us, that large serpents of any species will very often swallow the smaller ones indiscriminately. The black snakes are preserved on account of their dexterity in destroying rats; which animals they pursue to their hiding places in the roofs of houses, &c. with wonderful agility.

Coluber
Columba.

23. The annulatus, or little brown bead-snake, is always small, and is seldom found above ground, but commonly dug up, and found twisting about the roots of shrubs and plants. All the back and other parts of the body have transverse spots of brown and white so disposed as to have some resemblance to a string of English beads; whence probably it takes its name. It is quite harmless, and is a native of Virginia and Carolina.

24. The flagellum, or coach-whip snake, is of a brown colour, very long, slender, and active. It runs swiftly, and is quite inoffensive; but the Indians imagine it is able to cut a man in two with a jerk of its tail.

25. The fulvius, or corn-snake, is beautifully marked with red and white, resembling a species of Indian corn, whence its name. It is harmless as to its bite, but frequently robs hen-roosts.

26. The æstivus, or green snake, is all over of a green colour; it is of a small size, and easily becomes tame and familiar, inasmuch that some people will carry them in their bosom.

27. The fasciatus, or wampum snake, derives its name from its resemblance to the Indian wampum. It sometimes grows to the length of five feet; and, like other large snakes, is very voracious, but its bite is not venomous. The back is of a dark blue, the belly finely clouded with spots of a brighter blue; the head is small in proportion to the rest of the body.

COLUMBA, the PIGEON, in ornithology, a genus belonging to the order of passeræ. The characters of this genus are as follow: The bill is straight, and descends towards the point; the nostrils are oblong, and half covered with a soft tumid membrane; and the tongue is entire, i. e. not cloven. There are 40 species, all natives of different countries. The following are the most remarkable.

1. The ænas, or domestic pigeon, and all its beautiful varieties, derive their origin from one species, the *stock-dove*; the English name implying its being the stock or stem from whence the other domestic birds spring. These birds, as Varro observes, take their Latin name, *columba*, from their voice or cooing; and, had he known it, he might have added the British also; for *k'lommen*, *kylubman*, *kulm*, and *kolm*, signify the same bird. They were, and still are, to be found in most parts of our island in a state of nature; but probably the Romans first taught the Britons how to construct pigeon-houses, and make the birds domestic. The characters of the domestic pigeon are the following. It is of a deep bluish ash-colour; the breast dashed with a fine changeable green and purple; the sides of the neck with shining copper-colour; its wings marked with two black bars, one on the coverts of the wings, the other on the quill feathers; the back white, and the tail barred near the end with black. They weigh 14 ounces. In the wild state it breeds in holes of rocks and hollows of trees; for which reason some people stile it *columba cavernalis*, in opposition to the ring-dove, which makes its nest on the boughs of trees. Nature always preserves some agreement in the manners, characters, and colours of birds reclaimed from their wild state. This species of pigeon soon takes to build in artificial cavities, and from the temptation of a ready provision becomes easily domesticated. Multitudes of these wild birds

are

Columba.

are observed to migrate into the south of England : and, while the beech-woods were suffered to cover large tracts of ground, they used to haunt them in myriads, reaching in strings a mile in length, as they went out in the morning to feed. They visit Britain the latest of any bird of passage, not appearing till November, and retiring in the spring. Mr Pennant imagines, that the summer haunts of these creatures are in Sweden, as Mr Eckmark makes their retreat thence coincide with their arrival in Britain. Numbers of them, however, breed on cliffs of the coast of Wales, and of the Hebrides. The varieties produced from the domestic are very numerous, and extremely elegant ; they are distinguished by names expressive of their several properties, as *tumblers, carriers, jacobines, croppers, pouters, runts, turbits, owls, nuns*, &c. The most celebrated of these is the carrier, of which an account is already given under the article *CARRIER-Pigeon*. The nature of pigeons is to be gregarious ; to lay only two eggs, and to breed many times in the year. So quick is their increase, that the author of the "Oeconomy of Nature" observes, that in the space of four years, 14,760 pigeons may come from a single pair. They bill during their courtship : the male and female sit, and also feed their young, by turns : they cast provision out of their craw into the young ones mouth ; and drink, not by sipping, like other birds, but by continued draughts like quadrupeds ; and have mournful or plaintive notes.

2. The palumbus, or ring-dove is a native of Europe and Asia. It is the largest pigeon we have, and might be distinguished from all others by its size alone. Its weight is about 20 ounces ; its length 18, the breadth 30 inches. The head, back, and covers of the wings are of a bluish ash-colour : the lower side of the neck and breast are of a purplish red, dashed with ash-colour : on the hind part of the neck is a semi-circular line of white ; above and beneath that, the feathers are glossy, and of changeable colours as opposed to the light. This species forms its nest of a few dry sticks in the boughs of trees. Attempts have been made to domesticate them by hatching their eggs under the common pigeon in dove-houses ; but as soon as they could fly, they always take to their proper haunts. In the beginning of winter they assemble in great flocks, and leave off cooing, which they begin in March when they pair.

3. The turtur, or turtle-dove, is a native of India. The length is twelve inches and a half ; its breadth 21 ; the weight four ounces. The irides are of a fine yellow, and the eye-lids encompassed with a beautiful crimson circle. The chin and forehead are whitish ; the top of the head ash-coloured, mixed with olive. On each side of the neck is a spot of black feathers prettily tipped with white : the back ash-coloured, bordered with olive brown : the scapulars and covers of a reddish brown spotted with black : the breast of a light purplish red, having the verge of each feather yellow : the belly white. The tail is three inches and a half long ; the two middle feathers of a dusky brown ; the others black, with white tips ; the end and exterior side of the outmost feathers wholly white. In the breeding season these birds are found in Buckingham-shire, Gloucester-shire, Shrop-

shire, and the west of England. They are very shy and retired, breeding in thick woods, generally of oak : in autumn they migrate into other countries.

4. The passerina, or ground-dove of Carolina, is about the size of a lark. The bill is yellow, and black at the end ; the iris red ; the breast and whole front of a changeable purple, with dark purple spots ; the large quill-feathers are of a muddy purple ; the legs and feet of a dirty yellow ; but the whole bird has such a composition of colours in it, that a very particular description is impossible. They fly many of them together, and make short flights from place to place, generally lighting on the ground.

5. The migratoria, or pigeon of passage, is about the size of an English wood-pigeon ; the bill black ; iris red ; the head of a dusky blue ; the breast and belly of a faint red ; above the shoulder of the wing there is a patch of feathers shining like gold ; the wing is coloured like the head, having some few spots of black (except that the larger feathers of it are dark brown with some white on the exterior vanes ; the tail is very long, and covered with a black feather, under which the rest are white ; the legs and feet are red. They come in prodigious numbers from the north, to winter in Virginia and Carolina. In these countries they roost upon one another's backs in such quantities that they often break down the limbs of oaks which support them, and leave their dung some inches thick below the trees. In Virginia Mr Catesby has seen them fly in such continued trains for three days successively, that they were not lost sight of for the least interval of time, but somewhere in the air they were seen continuing their flight southward. They breed in rocks by the sides of rivers and lakes far north of St Laurence. They fly to the south only in hard winters, and are never known to return.

COLUMBA (St), in allusion to whose name the island of Jona (one of the Hebrides) received its name ; Jona being derived from a Hebrew word signifying a dove. This holy man, persecuted by his zeal, left his native country, Ireland, in the year 565, with the pious design of preaching the gospel to the Picts. It appears that he left his native soil with warm repentment, vowing never to make a settlement within sight of that hated island. He made his first trial at Oran-fay ; and finding that place too near to Ireland, succeeded to his wish at Hy, for that was the name of Jona at the time of his arrival. He repeated here the experiment on several hills, erecting on each a heap of stones ; and that which he last ascended is to this day called *Garnan-chul-reh-Eirinn*, or the eminence of the back turned to Ireland.

Columba was soon distinguished by the sanctity of his manners : a miracle that he wrought, so operated on the Pictish king Bradeus, that he immediately made a present of the little isle to the saint. It seems that his majesty had refused Columba an audience ; and even proceeded so far as to order the palace-gates to be shut against him : but the saint, by the power of his word, instantly caused them to fly open. As soon as he was in possession of Jona, he founded a cell of monks, borrowing his institutions from a certain oriental monastic order. It is said that the first religious were canons regular ; of whom the founder was

Columba.

Pennant's Tour.

Columbanus
↓
Columbo-root.

Columbo-root.

the first abbot: and that his monks, till the year 716, differed from those of the church of Rome, both in the observation of Easter, and in the clerical tonsure. Columba led here an exemplary life, and was highly respected for the sanctity of his manners for a considerable number of years. He is the first on record who had the faculty of *second sight*, for he told the victory of Aidan over the Picts and Saxons on the very instant it happened. He had the honour of burying in his island, Convallius and Kinnatli, two kings of Scotland, and of crowning a third. At length, worn out with age, he died, in Jona, in the arms of his disciples; was interred there, but (as the Irish pretend) in after times translated to Down; where, according to the epitaph, his remains were deposited with those of St Bridget and St Patrick.

Hi tres in *Duno* tumultu tumultantur in uno;
Brigida, Patricius, atque Columba pius.

But this is totally denied by the Scots; who affirm, that the contrary is shewn in a life of the saint, extracted out of the pope's library, and translated out of the Latin into Erse, by Father *Cail o boran*; which decides, in favour of Jona, the momentous dispute.

COLUMBANUS (St.), a Latin poet, was born in Ireland in 560. He retired from the world, and lived a solitary life in the mountains of Wales for some years. He next went over to France and built a monastery; but, being exiled from that country, he travelled to Italy, where he founded the abbey of Bobbio, and died in it in 615.

CULMBINE, in botany. See *AQUILEGIA*.

CULMBO-ROOT, an article newly introduced into the materia medica, of the natural history of which we know very little. Dr Percival is the only person who hath written particularly concerning it, and the substance of his account follows.

The Columbo-root grew originally on the continent of America; from whence it was transplanted to Columbo, a town in Ceylon, which gives name to it, and supplies all India with it. The inhabitants of these countries have for a long time used it in disorders of the stomach and bowels. They carry it about with them, and take it sliced or scraped in Madeira wine. This root comes to us in circular pieces, which are from half an inch or an inch to three inches in diameter; and divided into *frusta*, which measure from two inches to one quarter of an inch. The sides are covered with a thick corrugated bark, of a dark brown hue on its external surface, but internally of a light yellow colour. The surfaces of the transverse sections appear very unequal, highest at the edges, and forming a concavity towards the centre. On separating this surface, the root is observed to consist of three lamina, *viz.* the cortical, which, in the larger roots, is a quarter of an inch thick; the ligneous, about half an inch; and the medullary, which forms the centre, and is near an inch in diameter. This last is much softer than the other parts, and, when chewed, seems mucilaginous; a number of small fibres run longitudinally through it, and appear on the surface. The cortical and ligneous parts are divided by a black circular line. All the thicker pieces have small holes drilled through them, for the convenience of drying. Columbo-root has an aroma-

tic smell; but is disagreeably bitter, and slightly pungent to the taste, somewhat resembling mustard-seed, when it has lost, by long keeping, part of its essential oil. Yet, though ungrateful to the taste, when received into the stomach, it appears to be corroborant, antileptic, sedative, and powerfully antiemetic. In the cholera morbus it alleviates the violent *tormenta*, checks the purging and vomiting, corrects the putrid tendency of the bile, quiets the inordinate motions of the bowels, and speedily recruits the exhausted strength of the patient. It was administered to a great number of patients, sometimes upwards of 20 in a day, afflicted with the cholera morbus, by Mr Johnson of Chester, in 1756. He generally found that it soon stopped the vomiting, which was the most fatal symptom, and that the purging and remaining complaints quickly yielded to the same remedy. The dose he gave was from half a drachm to two drachms of the powder, every three or four hours, more or less, according to the urgency of the symptoms. Though this medicine possesses little or no astringency, it has been observed to be of great service in diarrheas, and even in the dysentery. In the first stage of these disorders, where astringents would be hurtful, Columbo-root may be prescribed with safety; as, by its antispasmodic powers, the irregular actions of the primæ viæ are corrected. But as a cordial, tonic, and antiseptic remedy, it answers better when given towards their decline. Its efficacy has also been observed in the vomitings which attend the bilious cholic; and in such cases, where an emetic is thought necessary, after administering a small dose of ipecacuan, the stomach may be washed with an infusion of Columbo-root. This will tend to prevent those violent and convulsive reachings which in irritable habits abounding with bile are sometimes excited by the mildest emetic. In bilious fevers, 15 or 20 grains of this root, with an equal or double quantity of vitriolated tartar, given every four, five, or six hours, produce very beneficial effects. From its efficacy in these bilious diseases of this country, it is probable that it may be useful in the yellow fever of the West Indies, which is always attended with great sickness, violent reachings, and a copious discharge of bile. The vomiting recurs at short intervals, often becomes almost incessant, and an incredible quantity of bile is sometimes evacuated in a few hours. Children during dentition are often subject to severe vomitings and diarrheas. In these cases the Columbo-root is an useful remedy, and hath often procured almost instant relief, when other efficacious remedies have been tried in vain. This root is also extremely beneficial in a languid state of the stomach, attended with want of appetite, indigestion, nausea and flatulence. It may be given either in substance, with some grateful aromatic, or infused in Madeira wine. Habitual vomiting, when it proceeds from a weakness or irritability of the stomach, from an irregular gout, acidities, acrimonious bile, or an increased and depraved secretion of the pancreatic juice, is greatly relieved by the use of Columbo-root, in conjunction with aromatics, chalybeates, or the testaceous powders. In the nausea and vomiting occasioned by pregnancy, an infusion of Columbo-root succeeds better than any other medicine that hath been tried.

From

Columbo
Columbus.

From Dr Percival's experiments on this root, it appears, that rectified spirit of wine extracts its virtues in the greatest perfection. The watery infusion is more perishable than that of other bitters. In 24 hours a copious precipitation takes place; and in two days it becomes ropy, and even multry. The addition of orange-peel renders the infusion of Columbo-root less ungrateful to the palate. An ounce of the powdered root, half an ounce of orange-peel, two ounces of French brandy, and 14 ounces of water, macerated 12 hours without heat, and then filtered through paper, afford a sufficiently strong and tolerably pleasant infusion. The extract made first by spirit and then with water, and reduced by evaporation to a pilular consistence, is found to be equal if not superior in efficacy to the powder. As an antiseptic, Columbo-root is inferior to the bark; but as a corrector of putrid gall, it is much superior to the bark; whence also it is probable that it would be of service in the West India yellow fever. It also restrains alimentary fermentation, without impairing digestion; in which property it resembles mustard. Hence its great service in preventing acidities. It hath also a remarkable power of neutralizing acids already formed. It doth not appear to have the least heating quality; and therefore may be used with propriety and advantage in the phthisis pulmonalis and in hectic cases, to correct acrimony and strengthen digestion. It occasions no disturbance, and agrees very well with a milk-diet, as it abates flatulence, and is indisposed to acidity.

COLUMBO, a maritime town of the island of Ceylon in the East Indies, seated on the fourth-west part of its coast, and subject to the Dutch. E. Long. 68. 10. N. Lat. 7. 5.

COLUMBUS, or *congregation of St COLUMBUS*, a society of regular canons, who formerly had 100 abbeys or monasteries in the British isles.

COLUMBUS (Christopher), a Genoese, the celebrated navigator, and first discoverer of the islands of America, was a subject of the republic of Genoa. Neither the time nor the place of his birth, however, are known with certainty; only he was descended of an honourable family, who, by various misfortunes, had been reduced to indigence. His parents were sea-faring people; and Columbus having discovered, in his early youth, a capacity and inclination for that way of life, was encouraged by them to follow the same profession. He went to sea at the age of 14: his first voyages were to those ports in the Mediterranean, frequented by the Genoese; after which he took a voyage to Iceland; and proceeding still further north, advanced several degrees within the polar circle. After this, Columbus entered into the service of a famous sea-captain of his own name and family. This man commanded a small squadron, fitted out at his own expence, and by cruising, sometimes against the Mahometans, and sometimes against the Venetians; the rivals of his country in trade, had acquired both wealth and reputation. With him Columbus continued for several years, no less distinguished for his courage than his experience as a sailor. At length, in an oblique engagement, off the coast of Portugal, with some Venetian caravels returning richly laden from the Low Countries, the vessel on board which he

Columbus.

served took fire, together with one of the enemies ships to which it was fast grappled. Columbus threw himself into the sea; laid hold of a floating oar; and by the support of it, and his dexterity in swimming, he reached the shore, though above two leagues distant.

After this disaster, Columbus repaired to Lisbon, where he married a daughter of Bartholomew Perestrelo, one of the captains employed by prince Henry in his early navigations, and who had discovered and planted the islands of Porto Santo and Madeira. Having got possession of the journals and charts of this experienced navigator, Columbus was seized with an irresistible desire of visiting unknown countries. In order to indulge it, he made a voyage to Madaira, and continued during several years to trade with that island, the Canaries, Azores, the settlements in Guinea, and all the other places which the Portuguese had discovered on the continent of Africa.

By the experience acquired in such a number of voyages, Columbus now became one of the most skillful navigators in Europe. At this time, the great object of discovery was a passage by sea to the East Indies. This was attempted, and at last accomplished by the Portuguese, by doubling the Cape of Good Hope. The danger and tediousness of the passage, however, supposing it to be really accomplished, which as yet it was not, set Columbus on considering whether a shorter and more direct passage to these regions might not be found out; and after long consideration, he became thoroughly convinced, that, by sailing across the Atlantic ocean, directly towards the west, new countries, which probably formed a part of the vast continent of India, must infallibly be discovered. His reasons for this were, in the first place, a knowledge he had acquired of the true figure of the earth. The continents of Europe, Asia, and Africa, as far as then known, form but a small part of the globe. It was suitable to our ideas, concerning the wisdom and beneficence of the Author of nature, to believe, that the vast space, still unexplored, was not entirely covered by a waste and barren ocean, but occupied by countries fit for the habitation of man. It appeared likewise extremely probable, that the continent on this side the globe was balanced by a proportional quantity of land in the other hemisphere. These conjectures were confirmed by the observations of modern navigators. A Portuguese pilot, having stretched farther to the west than was usual at that time, took up a piece of timber, artificially carved, floating upon the sea; and as it was driven towards him by a westerly wind, he concluded that it came from some unknown land situated in that quarter. Columbus's brother-in-law had found to the west of the Madeira isles, a piece of timber fashioned in the same manner, and brought by the same wind; and had seen also canes of an enormous size floating upon the waves, which resembled those described by Ptolemy, as productions peculiar to the East Indies. After a course of westerly winds, trees, torn up by the roots, were often driven upon the coasts of the Azores; and at one time the dead bodies of two men, with singular features, which resembled neither the inhabitants of Europe nor Africa, were cast ashore there. The most cogent reason, however, was a mistaken notion of the

the.

Columbus. the ancient geographers, concerning the immense extent of the continent of India. Though hardly any of them had penetrated beyond the river Ganges, some Greek writers had ventured to describe the provinces beyond that river, which they represented as regions of an immense extent. Ctesias affirmed that India was as large as all the rest of Asia. Onesicritus, whom Pliny the naturalist follows, contended that it was equal to a third part of the habitable earth. Nearchus asserted that it would take four months to march from one extremity of it to the other in a straight line. The journal of Marco Polo, who travelled into Asia in the 13th century, and who had proceeded towards the east far beyond the limits to which any European had ever advanced, seemed also so much to confirm these accounts, that Columbus was persuaded, that the distance from the most westerly part of Europe, to the most easterly part of Asia, was not very considerable; and that the shortest as well as most direct course to the remote regions of the east, was to be found by sailing due west.

In 1474, Columbus communicated his ideas on this subject to one Paul a physician in Florence, a man eminent for his knowledge in cosmography. He approved of the plan, suggested several facts in confirmation of it, and warmly encouraged Columbus to persevere in an undertaking so laudable, and which must redound so much to the honour of his country, and the benefit of Europe. Columbus, fully satisfied of the truth of his system, was impatient to set out on a voyage of discovery. The first step towards this was to secure the patronage of some of the considerable powers of Europe capable of undertaking such an enterprise. He applied first to the republic of Genoa; but his countrymen, strangers to his abilities, inconsistently rejected his proposal as the dream of a chimerical projector, and thus lost forever the opportunity of restoring their commonwealth to its ancient lustre. His next application was to the court of Portugal, where king John II. listened to him in the most gracious manner, and referred the consideration of his plan to Diego Ortiz, bishop of Ceuta, and two Jewish physicians, eminent cosmographers, whom he was accustomed to consult in matters of this kind. Unhappily these were the persons who had been the chief directors of the Portuguese navigations, and had advised to search for a passage to India by steering a course directly opposite to that which Columbus had recommended as shorter and more certain. They could not therefore approve of his proposal, without submitting to the double mortification of condemning their own theory, and of acknowledging his superiority. The result of their conferences was, that they advised the king to fit out a vessel privately, in order to attempt the proposed discovery, by following exactly the course which Columbus seemed to point out. John, forgetting on this occasion the sentiments of a monarch, meekly adopted this perfidious counsel. But the pilot, chosen to execute Columbus's plan, had neither the genius nor fortune of its author. Contrary winds arose; no sign of approaching land appeared; his courage failed; and he returned to Lisbon, execrating the project as equally extravagant and dangerous.

On discovering this dishonourable transaction, Co-

lumbus immediately quitted Portugal, and applied to the king of Spain; but lest he should be here again appointed, he sent his brother Bartholomew into England, to whom he had fully communicated his ideas, in order that he might negotiate at the same time with Henry VII. who was reckoned one of the most sagacious as well as opulent princes of Europe. Bartholomew was very unfortunate in his voyage: he fell into the hands of pirates, who stripped him of every thing, and detained him a prisoner for several years. At last he made his escape, and arrived in London, but in such extreme indigence, that he was obliged to employ himself, during a considerable time, in drawing and selling maps, in order to pick up as much money as would purchase a decent dress in which he might venture to appear at Court. The proposals were received by Henry with more approbation than by any monarch to whom they had hitherto been presented.

Columbus himself made his proposals to the king of Spain, not without many doubts of success, which soon appeared to be well founded. True science had as yet made so little progress in the kingdom of Spain, that most of those to whom the consideration of his plan was referred were utterly ignorant of the first principles on which he founded his hopes. Some, from mistaken notions concerning the dimensions of the globe, contended that a voyage to those remote regions of the East which Columbus expected to discover, could not be performed in less than three years. Others concluded, that either he would find the ocean of infinite extent, according to the opinion of some ancient philosophers; or that if he should persist in steering westwards beyond a certain point, the convex figure of the globe must infallibly prevent his return, and he must perish in the vain attempt to unite the two opposite hemispheres, which nature had for ever dijoined. Even without deigning to enter into any particular discussion, some rejected the scheme in general, upon the credit of a maxim made use of by the ignorant in all ages, "That it is presumptuous in any person to suppose that he alone possesses knowledge superior to all the rest of mankind united." By continual disappointments and delays, he was at last wearied out, and resolved to repair to the court of England in person, in hopes of meeting with a favourable reception there. He had already made preparations for this purpose, and taken measures for the disposal of his children during his absence, when Juan Perez, the prior of the monastery of Rabida near Palos, in which they had been educated, earnestly solicited him to defer his journey for a short time. Perez was a man of considerable learning, and some credit with queen Isabella. To her therefore he applied; and the consequence of his application was a gracious invitation of Columbus back to court, accompanied with the present of a small sum to equip him for the journey. Ferdinand, however, still regarded the project as chimerical; and had the address to employ, in this new negotiation with him, some of the persons who had formerly pronounced his scheme to be impracticable. To their astonishment, Columbus appeared before them with the same confident hopes of success as formerly, and insisted

Columbus. insisted on the same high recompence. He proposed that a small fleet should be fitted out, under his command, to attempt the discovery; and demanded to be appointed perpetual and hereditary admiral and viceroy of all the seas and lands which he should discover; and to have the tenth of the profits arising from them settled irrevocably upon him and his descendants forever. At the same time he offered to advance the eighth part of the sum necessary for accomplishing his design, on condition that he should be entitled to a proportional share in the adventure. If the enterprize should totally miscarry, he made no stipulation for any reward or emolument whatever. These demands were thought unreasonable; Isabella broke off the treaty she had begun, and Columbus was once more disappointed. He now resolved finally to leave Spain; and had actually proceeded some leagues on his journey, when he was overtaken by a messenger from Isabella, who had been prevailed upon by the arguments of Quintanilla and Santangel, two of Columbus's patrons, again to favour his undertakings. The negotiation now went forward with all manner of facility and dispatch; and a treaty with Columbus was signed on the 17th of April 1492. The chief articles of it were, that Columbus should be constituted high admiral in all the seas, islands and continents he should discover, with the same powers and prerogatives that belonged to the high admiral of Castile within the limits of his jurisdiction. He was also appointed viceroy in all those countries to be discovered; and a tenth of the profits accruing from their productions and commerce was granted to him forever. All controversies or law-suits with respect to mercantile transactions were to be determined by the sole authority of Columbus, or of judges to be appointed by him. He was also permitted to advance one-eighth part of the expence of the expedition, and of carrying on commerce with the new countries; and was entitled, in return, to an eighth part of the profit. But, though the name of Ferdinand was joined with Isabella in this transaction, his distrust of Columbus was still so violent that he refused to take any part in the enterprize as king of Arragon; and as the whole expence of the expedition was to be defrayed by the crown of Castile, Isabella reserved for her subjects of that kingdom an exclusive right to all the benefits which might accrue from its success.

At last our adventurer set sail with three small ships, the whole expence of which did not exceed L. 4000. During his voyage he met with many difficulties from the mutinous and timid disposition of his men. He was the first who observed the variation of the compass, which threw the sailors into the utmost terror. For this phenomenon, Columbus was obliged to invent a reason, which though it did not satisfy himself, yet served to dispel their fears, or silence their murmurs. At last, however, the sailors lost all patience; and the admiral was obliged to promise solemnly, that in case land was not discovered in three days he should return to Europe. That very night, however, the island of San Salvador was discovered, which quickly put an end to all their fears. The sailors were then as extravagant in the praise of Columbus, as they had before been insolent in reviling and threatening him.

They threw themselves at his feet, implored his pardon, and pronounced him to be a person inspired by heaven with more than human sagacity and fortune, in order to accomplish a design so far beyond the ideas and conception of all former ages. Having visited several of the West-India islands, and settled a colony in Hispaniola*, he again set sail for Spain; and after eluding great dangers from violent tempests, arrived at the port of Palos on the 15th of March 1493.

As soon as Columbus's ship was discovered approaching, all the inhabitants of Palos ran eagerly to the shore, where they received the admiral with royal honours. The court was then at Barcelona, and Columbus took care immediately to acquaint the king and queen of his arrival. They were no less delighted than astonished with this unexpected event. They gave orders for conducting him into the city with all imaginable pomp. They received him clad in their royal robes, and seated on a throne under a magnificent canopy. When he approached, they stood up, and, raising him as he kneeled to kiss their hands, commanded him to take his seat upon a chair prepared for him, and to give a circumstantial account of his voyage. When he had finished his oration, which he delivered with much modesty and simplicity, the king and queen, kneeling down, offered up solemn thanks to God for the discovery. Every possible mark of honour that could be suggested by gratitude or admiration was conferred on Columbus; the former capitulation was confirmed, his family was ennobled, and a fleet was ordered to be equipped, to enable him to go in quest of those more opulent countries which he still confidently expected to find.

Notwithstanding all this respect, however, Columbus was no longer regarded than he was successful. The colonists he carried over with him were to the last degree unreasonable and unmanageable; so that he was obliged to use some severities with them; and complaints were made to the court of Spain against him for cruelty. On this, Francis de Bovadilla, a knight of Calatrava, was appointed to inquire into the conduct of Columbus; with orders, in case he found the charge of maladministration proved, to supersede him, and assume the office of governor of Hispaniola. The consequence of this was, that Columbus was sent to Spain in chains. From there, however, he was freed immediately on his arrival, and had an opportunity granted him of vindicating his innocence. He was however deprived of all power; and notwithstanding his great services, and the solemnity of the agreement between him and Ferdinand, Columbus never could obtain the fulfilment of any part of that treaty. At last, disgusted with the ingratitude of a monarch whom he had served with such fidelity and success, and exhausted with fatigues, he ended his life on the 29th of May 1506.

COLUMBUS (Bartholomew), brother to Christopher, famous for his marine charts and spheres, which he presented to Henry VII. of England. He died in 1514.

COLUMBUS (Don Ferdinand), son of Christopher, and writer of his life. He entered into the ecclesiastical state; and founded a library, which he bequeathed to the church of Seville, to this day called the *Columbine library*. He died in 1560.

Columella
||
Colum.

COLUMELLA (Lucius Junius Moderatus), a Roman philosopher, was a native of Cadiz, and lived under the emperor Claudius, about the year 42. He wrote a book on agriculture, intitled *De Re rustica*, and another *De Arboribus*.

COLUMEY, a town of Red Ruffia in Poland, seated on the river Pruth, towards the confines of Moldavia, about 38 miles from Halez, and 63 south of Leopold. This town has been very ill treated by the Cossacks, inasmuch that it is now inconsiderable, though there are several mines of salt in its district. E. Long. 16. 25. N. Lat. 48. 45.

COLUMN, in architecture, a round pillar made to support and adorn a building, and composed of a base, a shaft, and a capital. See ARCHITECTURE, n^o 38.

COLUMNS, denominated from their use.—Astronomical **COLUMN**, is a kind of observatory, in form of a very high tower built hollow, and with a spiral ascent to an armillary sphere placed a-top for observing the motions of the heavenly bodies. Such is that of the Doric order erected at the Hotel de Soissons at Paris by Catharine de Medicis for the observations of Orontius Fincus, a celebrated astronomer of that time.

Chronological COLUMN, that which bears some historical inscription digested according to the order of time; as by lustres, olympiads, fasti, epochas, annals, &c. At Athens, there were columns of this kind, whereon were inscribed the whole history of Greece digested into olympiads.

Funerary COLUMN, that which bears an urn, whereon are supposed to be inclosed the ashes of some deceased hero; and whose shaft is sometimes overpiped with tears and flames, which are symbols of grief and of immortality.

Gnomonic COLUMN, a cylinder whereon the hour of the day is represented by the shadow of a stile. See DIAL.

Historical COLUMN, is that whose shaft is adorned with a basso-relievo, running in a spiral line its whole length, and containing the history of some great personage: such are the *Trajan* and *Antonine* columns at Rome.

Hollow COLUMN, that which has a spiral stair-case within, for the convenience of ascending to the top; as the *Trajan* column, the stair-case whereof consists of 185 steps, and is illuminated by 43 little windows, each of which is divided by tambours of white marble. The monument, or fire-column, at London, has also a stair-case; but it does not reach to the top. These kinds of columns are also called *columna coelices*, or *coeliceæ*.

Indicative COLUMN, that which serves to show the tides, &c. along the sea-coasts. Of this kind there is one at Grand Cairo of marble, whereon the overflowings of the Nile are expressed: by this they form a judgment of the succeeding season; when the water, for instance, ascends to 23 feet, it is a sign of great fertility in Egypt. See NILOMETER.

Instructive COLUMN, that raised, according to Josephus, lib. i. cap. 3. by the sons of Adam, whereon were engraven the principles of arts and sciences. Baudelot tells us, that the son of Pisisstratus raised another of this kind, of stone, containing the rules and precepts of agriculture.

Itinerary COLUMN, a column with several faces, placed in the cross-ways in large roads; serving to show the different routs by inscriptions thereon.

Lactary COLUMN, at Rome, according to Festus, was a column erected in the herb-market, now the place *Montanara*, which had a cavity in its pedestal, wherein young children abandoned by their parents, out of poverty or inhumanity, were exposed, to be brought up at the public expence.

Legal COLUMN. Among the Lacedemonians there were columns raised in public places, whereon were engraven the fundamental laws of the state.

Limitrophic or Boundary COLUMN, that which shows the limits of a kingdom or country conquered. Such was that which Pliny says Alexander the Great erected at the extremity of the Indies.

Manubary COLUMN, from the Latin *manubie*, "spoils of the enemy;" a column adorned with trophies built in imitation of trees, whereon the spoils of enemies were anciently hung. See TROPHY.

Memorial COLUMN, that raised on occasion of any remarkable event; as the monument of London, built to perpetuate the memory of the burning of that city in 1666. It is of the Doric order, fluted, hollow, with a winding stair-case; and terminated a-top with waving flames. There is also another of the kind, in form of an obelisk, on the banks of the Rhine in the Palatinate, in memory of the famous passage of that river by the great Gustavus Adolphus and his army.

Menian COLUMN, any column which supports a balcony or meniana. The origin of this kind of column, Suetonius and Alcanius refer to one Menias; who having sold his house to Cato and Flaccus, consuls, to be converted into a public edifice, reserved to himself the right of raising a column without side, to bear a balcony, whence he might see the shews.

Miliary COLUMN, was a column of marble raised by order of Augustus in the middle of the Roman forum; from whence, as a centre, the distances of the several cities, &c. of the empire were reckoned, by other miliary columns disposed at equal distances on all the grand roads. This column was of white marble, the same with that which is now seen on the balustrade of the perron of the capitol at Rome. Its proportion is massive, being a short cylinder, the symbol of the globe of the earth. It was called *miliareum aureum*, as having been gilt, at least the ball, by order of Augustus. It was restored by the emperors Vespasian and Adrian, as appears by the inscriptions.

Military COLUMN, among the Romans, a column whereon was engraven a list of the forces in the Roman army, ranged by legions, in their proper order; with design to preserve the memory of the number of soldiers, and of the order preserved in any military expedition. They had another kind of military column, which they called *columna bellica*, standing before the temple of Janus; at the foot whereof the consul declared war, by throwing a javelin towards the enemies countries.

Sepulchral COLUMN, anciently was a column erected on a tomb or sepulchre, with an inscription on its base. Those over the tombs of persons of distinction were very large; those for the common people small: these last are called *stelæ* and *cippi*.

Statuary

Statuary COLUMN, that which supports a statue. Such was that erected by pope Paul V. on a pedestal before the church of St Maria at Rome; to support a statue of the Virgin, which is of gilt brass. This column was dug up in the temple of peace; its shaft is a single block of white marble 49 feet high, and five feet eight inches diameter, of the Corinthian order.

The term *statuary column* may likewise be applied to caryatides, peristans, termini, and other human figures, which do the office of columns; and which Vitruvius calls *telamones*, and *atlantes*. See ARCHITECTURE, n° 59.

Triumphal COLUMN, a column erected among the ancients in honour of an hero; the joints of the stones, or courses whereof, were covered with as many crowns as he had made different military expeditions. Each crown had its particular name, as *vallis*, which was beset with spikes, in memory of having forced a palisade. *Muralis*, adorned with little turrets or battlements, for having mounted an assault. *Navalis*, of prows and beaks of vessels; for having overcome at sea. *Obsidionalis*, or *graninalis*, of grails; for having raised a siege. *Qvanti*, of myrtle; which expressed an ovation, or little triumph: and *triumphalis*, of laurel, for a grand triumph. See CROWN.

COLUMNÆA, in botany, a genus of the angiospermia order, belonging to the didynamia class of plants. There is but one species, a native of Martinnico, of which we have no particular description.

COLUMNIFERI, in botany, an order of plants in the *fragmenta methodi naturalis* of Linnæus, in which are the following genera, *viz.* bixa, corchorus, heliocarpus, kiggelaria, microcos, muntingia, thea, tilea, turnera, triumfetta, ayenia, grevia, helicteres, kleinhovia, adanfonia, alcea, althea, bombax, camellia, golyptium, hermannia, hibiscus, lavatera, malope, malva, melochia, napæa, pentapetes, sida, stewartia, theobroma, urena, waltharia.

COLURES, in astronomy and geography, two great circles supposed to intersect each other at right angles in the poles of the world, and to pass through the solstitial and equinoctial points of the ecliptic. See GEOGRAPHY.

COLURI, a little island in the gulph of Engia, in the Archipelago, formerly called *Salamis*. The principal town is of the same name, and seated on the south side, at the bottom of the harbour, which is one of the finest in the world. The famous Grecian hero, Ajax, who makes such a figure in Homer's Iliad, was king of this island. It is now, however, but a poor place; its commodities consist of wheat, barley, tar, rosin, pit-coal, sponges, and pot-alies, which they carry to Athens. It is seven miles south from Athens, and is separated from the continent by a strait about a mile over.

COLUTEA, **RASTARD-SENA**, in botany; a genus of the decandria order, belonging to the diadelphia class of plants. There are three species, all of them deciduous flowering shrubs, adorned with many lobed leaves, and butterfly-shaped flowers, of a deep yellow or red colour. They are propagated both by seeds and layers, and are hardly enough, though they sometimes require a little shelter, when the weather is very cold.

COLYMBUS, in ornithology, a genus belonging to the order of anseres. The bill has no teeth, is subu-

lated, straight, and sharp-pointed; the teeth are in the throat; the nostrils are linear, and at the base of the bill; and the legs are unfit for walking. This genus includes the grebes and divers. The species are eleven.

1. The grylle is in length 14 inches, in breadth 22; the bill is an inch and an half long, straight, slender, and black; the inside of the mouth red; on each wing is a large bed of white, which in young birds is spotted; the tips of the lesser quill-feathers, and the coverts of the wings, are white: except those, the whole plumage is black. In winter it is said to change to white; and a variety spotted with black and white is not uncommon in Scotland. The tail consists of 12 feathers; the legs are red. These birds are found on the Bass Isle in Scotland; in the island of St Kilda; and, as Mr Ray imagines, in the Fam Islands off the coast of Northumberland. It has also been seen on the rocks of Llandidno, in Caernarvonshire, in Wales. Except in breeding-time it keeps always at sea; and is very difficult to be shot, diving at the flash of the pan. The Welsh call this bird *cafgan longur*, or "the sailor's hatred," from a notion that its appearance forebodes a storm. It visits St Kilda's in March; makes its nest far under ground; and lays a grey egg, or, as Steller says, whitish and spotted with rust, and speckled with ash-colour.

2. The trille weighs 24 ounces; its length is 17 inches, the breadth 27½; the bill is three inches long, black, straight, and sharp-pointed; near the end of the lower mandible is a small process; the inside of the mouth yellow; the feathers on the upper part of the bill are short and soft like velvet; from the eye to the hind part of the head is a small division of the feathers. The head, neck, back, wings, and tail, are of a deep mouse-colour; the tips of the lesser quill-feathers white; the whole under part of the body is of a pure white; the sides under the wings marked with dusky lines. Immediately above the thighs are some long feathers that curl over them. The legs are dusky. They are found in amazing numbers on the high cliffs of several of the British coasts, and appear at the same time with the auk. They are very simple birds; for notwithstanding they are shot at, and see their companions killed by them, they will not quit the rock. Like the auk they lay only one egg, which is very large; some are of a fine pale blue; others white, spotted, or most elegantly streaked with lines crossing each other in all directions. They continue about the Orkneys the whole winter.

3. The septentrionalis is more elegantly shaped than the others. It weighs three pounds. The length to the end of the tail is two feet; to the toes, two feet four inches: the breadth, three feet five inches. The head is small and taper; the bill straight; the head and chin are of a fine uniform grey; the hind part of the neck marked with dusky and white lines pointing downwards; the throat is of a dull red; the whole upper part of the body, tail, and wings, of a deep grey, almost dusky; but the coverts of the wings and the back are marked with a few white spots; the under side of the body is white; the legs dusky. This species breeds in the northern parts of Europe, on the borders of lakes; but migrates southward during winter. They build their nests upon the shore without

4. The arcticus is somewhat larger than the last: the bill is black, and also the front; the hind part of the head and neck cinereous; the sides of the neck marked with black and white lines pointing downwards; the fore part of a glossy variable black, purple, and green. The back, scapulars, and coverts of the wings, are black, marked, the two first with square, the last with round spots of white; the quill-feathers dusky; the breast and belly white; the tail short and black; legs partly dusky, and partly reddish.

5. The glacialis is three feet five inches in length; the breadth four feet eight; the bill to the corners of the mouth four inches long, black and strongly made. The head and neck are of a deep black; the hind part of the latter is marked with a large feminar white band; immediately under the throat is another; both marked with black oblong strokes pointing down: the lower part of the neck is of a deep black, glossed with a rich purple; the whole under side of the body is white; the sides of the breast marked with black lines; the back, coverts of the wings, and scapulars, are black marked with white spots; those on the scapulars are very large, and of a square shape; two at the end of each feather. The tail is very short, and almost concealed by the coverts, which are dusky, spotted with white; the legs are black. These birds inhabit the northern parts of Britain, live chiefly at sea, and feed on fish; but it is not known whether they breed here as they do in Norway, which has many birds in common with Scotland. In the Highlands it is called *myr-buachail*, or "the herdsman of the sea," from its being so much in that element.

6. The immer, or ember-geofe, is superior in size to a common geofe. The head is dusky; the back, coverts of the wings, and tail, clouded with lighter and darker shades of the same. The primaries and tail are black; the under side of the neck spotted with dusky; the breast and belly silvery; the legs black. They inhabit the seas about the Orkney Islands; but in severe winters visit the southern parts of Great Britain. They live so much at sea, that it has been imagined they never quitted the water; and that the young were hatched in a hole formed by nature under the wing for that end. Their skins are uncommonly tough, and in the northern countries have been used as leather.

7. The crystalus, or cargoofe, weighs two pounds and an half. Its length is 21 inches, the breadth 30; the bill is two inches and a quarter long, red at the base, and black at the point; between the bill and the eyes is a stripe of black naked skin; the irides are of a fine pale red; the tongue is a third part shorter than the bill, slender, hard at the end, and a little divided; on the head is a large dusky crest, separated in the middle. The cheeks and throat are surrounded with a long pendent ruff, of a bright tawney colour, edged with black; the chin is white; from the bill to the eye is a black line, and above that a white one; the hind part of the neck and the back are of a footy hue; the rump, for it wants a tail, is covered with long soft down. The covert-feathers on the second and third joints of the wing, and the under coverts are white;

all the other wing-feathers, except the secondaries, are dusky, those being white; the breast and belly are of a most beautiful silvery white, glossy as satin: the outside of the legs, and the bottom of the feet, are dusky; the inside of the legs, and the toes, of a pale green. These birds frequent the meres of Shropshire and Cheshire, where they breed; and the great fen of Lincolnshire, where they are called *gaunts*. Their skins are made into tippets, and sold at as high a price as those which come from Geneva. This species lays four eggs of a white colour, and the same size with those of a pigeon. The nest is formed of the roots of hughane, stalks of water-lily, pond-weed, and water-violet, floating independent among the reeds and flags; the water penetrates it, and the bird sits and hatches the eggs in that wet condition; the nest is sometimes blown from among the flags into the middle of the water; in these circumstances the fable of the halcyon's nest may, in some measure, be vindicated. It is a careful nurse of its young; being observed to feed them most assiduously, commonly with small eels; and when the infant-brood are tired, the parent will carry them either on its back, or under its wings. It preys on fish, and is almost perpetually diving; it does not show much more than the head above water; and is very difficult to be shot, as it darts down on the least appearance of danger. It is never seen on land; and, though disturbed ever so often, will not fly farther than the end of the lake. Its skin is out of season about February, losing then its bright colour; and in the breeding time its breast is almost bare. The flesh is excessively rank.

8. The auritus, or eared dob-chick, is in length one foot to the rump; the extent is 22 inches: the bill black, slender, and slightly recurved; the irides crimson; the head and neck are black; the throat spotted with white; the whole upper side of a blackish brown, except the ridge of the wing about the first joint, and the secondary feathers, which are white; the breast, belly, and inner coverts of the wings are white; the subaxillary feathers, and some on the side of the rump ferruginous. Behind the eyes, on each side, is a tuft of long, loose, rust coloured feathers hanging backwards; the legs are of a dusky green. They inhabit the fens near *Spalding*, where they breed. No external difference is to be observed between the male and the female of this species. They make their nest not unlike that of the former; and lay four or five small eggs.

9. The urinator differs from the crystalus only in being rather less, and wanting the crest and ruff. The sides of the neck are striped downwards from the head with narrow lines of black and white: in other respects the colours and marks agree with that bird. This species has been shot on Rostern Mere in Cheshire. It is rather scarce in England, but is common in the winter time on the lake of Geneva. They appear there in flocks of 10 or twelve; and are killed for the sake of their beautiful skins. The under side of them being dressed with the feathers on, are made into muffs and tippets: each bird sells for about 14 shillings.

10. The dominicus, with lobated feet, a smooth head, and the belly very much spotted.

11. The padiceps, or pied-bill dob-chick, weighs half

half a pound; the eyes are large and encompassed with a white circle; the throat has a black spot; a black list crosses the middle of the bill; the lower mandible next the basis has a black spot. The head and neck are brown; the crown of the head and back part of the neck are darkest; the feathers of the breast are light brown mixed with green; the belly is dusky white; the back and wings brown; they frequent many of the fresh water ponds in the inhabited parts of Carolina.

COM, a town of Asia in the empire of Persia, and province of Iracagemi. It is a large populous place, but has suffered greatly by the civil wars. E. Long. 49. I. N. Lat. 34. O.

COMA, or COMA-VIGIL, a preternatural propensity to sleep, when, nevertheless, the patient does not sleep, or if he does, awakes immediately without any relief. See (the *Index* subjoined to) MEDICINE.

COMA *Berenices*, Berenice's hair, in astronomy, a constellation in the northern hemisphere, composed of stars near the lion's tail. This constellation consists of three stars, according to Ptolemy; of 13, according to Tycho; and of 40, in the Britannic Catalogue.

COMA *Somnolentum*, is when the patient continues in a profound sleep, and, when awaked, immediately relapses, without being able to keep open his eyes.

COMARUM, MARSH-CINQUEFOIL; a genus of the polygynia order, belonging to the icofandria class of plants. There is but one species, a native of Britain. It rises about two feet high, and bears fruit somewhat like that of the strawberry. It grows naturally in bogs, so is not easily preserved in gardens. The root dyes a dirty red. The Irish rub their milking pails with it, and it makes the milk appear thicker and richer. Goats eat the herb; cows and sheep are not fond of it; horses and swine refuse it.

COMB, an instrument to clean, untangle, and dress, flax, wool, hair, &c.

Combs for wool are prohibited to be imported into England.

COMB is also the crest, or red fleshy tuft, growing upon a cock's head.

COMBAT, in a general sense, denotes an engagement, or a difference decided by arms. See BATTLE.

COMBAT, in our ancient law, was a formal trial of some doubtful cause or quarrel, by the swords or bastons of two champions. This form of proceeding was very frequent, not only in criminal but in civil causes; being built on a supposition that God would never grant the victory but to him who had the best right. The last trial of this kind in England, was between Donald lord Ray appellant, and David Ramsay Esq; defendant; when after many formalities, the matter was referred to the King's pleasure. See the article BATTLE.

COMBINATION, properly denotes an assemblage of several things two by two.

COMBINATION, in mathematics, is the variation or alteration of any number of quantities, letters, or the like, in all the different manners possible. See CHANGES.

Aphorism. I. In all combinations, if from an arithmetic decreasing series, whose first term is the number out of which the combinations are to be formed, and

whose common difference is 1, there be taken as many terms as there are quantities to be combined; and these terms be multiplied into each other: and if from the series 1, 2, 3, 4, &c. there may be taken the same number of terms, and they be multiplied into each other, and the first product be divided by the second; the quotient will be the number of combinations required. Therefore, if you would know how many ways four quantities can be combined in seven, multiply the first four terms of the series, 7, 6, 5, 4, &c. together, and divide the product, which will be 840, by the product of the first four terms of the series, 1, 2, 3, 4, &c. which is 24, and the quotient 35 will be the combinations of 4 in 7. II. In all permutations, if the series 1, 2, 3, 4, &c. be continued to as many terms as there are quantities to be changed, and those terms be multiplied into each other; the product will be the number of permutations sought. Thus, if you would know how many permutations can be formed with five quantities, multiply the terms 1, 2, 3, 4, 5 together, and the product 120 will be the number of all the permutations.

Problems. I. To find the number of changes that may be rung on 12 bells. It appears by the second aphorism, that nothing is more necessary here than to multiply the numbers from 1 to 12 continually into each other, in the following manner, and the last product will be the number sought.

1

11
39916800
12
479,001,600

II. Suppose the letters of the alphabet to be wrote so final that no one of them shall take up more space than the hundredth part of a square inch: to find how many square yards it would require to write all the permutations of the 24 letters in that size. By following the same method as in the last problem, the number of permutations of the 24 letters will be found to be 62,044,840,173,323,943,936,000. Now the inches in a square yard being 1296, that number multiplied by 100 gives 129600, which is the number of letters

Combina-
tion.Combina-
tion.

letters each square yard will contain; therefore if we divide 62,044,840,173,323,943,936,000 by 129600 the quotient, which is 478,741,050,720,092,160, will be the number of yards required, to contain the above-mentioned number of permutations. But as all the 24 letters are contained in every permutation, it will require a space 24 times as large; that is, 11,489,785,217,282,211,840. Now the number of square yards contained on the surface of the whole earth is but 617,197,435,008,000, therefore it would require a surface 18620 times as large as that of the earth to write all the permutations of the 24 letters in the size above-mentioned.

III. To find how many different ways the eldest hand at piquet may take in his five cards. The eldest hand having 12 cards dealt him, there remain 20 cards, any five of which may be in those he takes in; consequently we are here to find how many ways five cards may be taken out of 20. Therefore, by aphorism I. if we multiply 20, 19, 18, 17, 16, into each other, which will make 1860480, and that number be divided by 1, 2, 3, 4, 5, multiplied into each other, which make 120, the quotient, which is 15504, will be the number of ways five cards may be taken out of 20. From hence it follows, that it is 15503 to 1, that the eldest hand does not take in any five certain cards.

IV. To find the number of deals a person may play at the game of whist, without ever holding the same cards twice. The number of cards played with at whist being 52, and the number dealt to each person being 13, it follows, that by taking the same method as in the last experiment, that is, by multiplying 52 by 51, 50, &c. so on to 41, which will make 3,954,242,643,911,239,680,000, and then dividing that sum by 1, 2, 3, &c. to 13, which will make 6,227,020,800, the quotient, which is 635,013,559,600 will be the number of different ways 13 cards may be taken out of 52, and consequently the number sought.

THE ARITHMETIC TRIANGLE; OR TABLE FOR COMBINATIONS.

Rank	A	B
1	1	1
2	2	1
3	3	3
4	4	6
5	5	10
6	6	15
7	7	21
8	8	28
9	9	36
10	10	45
11	11	55
12	12	66

The construction of this table is very simple. The line A *a* consists of the first 12 numbers. The line A *b* consists every where of units; and second term 3, of the line B *c*, is composed of the two terms 1 and 2 in the preceding rank: the third term 6, in that line, is formed of the two terms 3 and 3 in the preceding rank: and so of the rest; every term, after the first, being composed of the two next terms in the preceding rank: and by the same method it may be continued to any number of ranks. To find by this table how often any number of things can be combined in another number, under 13, as suppose 5 cards out of 8; in the eighth rank look for the fifth term, which is 56, and that is the number required.

Though we have shewn in the foregoing problems the manner of finding the combination of all numbers whatever, yet as this table answers the same purpose, for small numbers, by inspection only, it will be found useful on many occasions; as will appear by the following examples.

- V. To find how many different sounds may be produced by striking on a harpsichord two or more of the seven natural notes at the same time. 1. The combinations of two in seven, by the foregoing triangle are
2. The combinations of 3 in 7, are
3. The combinations of 4 in 7, are
4. The combinations of 5, are
5. The combinations of 6, are
6. The seven notes all together once

Therefore the number of all the sounds will be

VI. Take four square pieces of pasteboard, of the same dimension, and divide them diagonally, that is by drawing a line from two opposite angles, as in the figures, into 8 triangles; paint 7 of these triangles with the primitive colours, red, orange, yellow, green, blue, indigo, violet, and let the eighth be white. To find how many chequers or regular four-sided figures, different either in form or colour, may be made out of those eight triangles. First, by combining two of these triangles, there may be formed either the triangular square A, or the inclined square B called a *rhomb*. Secondly, by combining four of the triangles, the large square C, may be formed; or the long square D, called a *parallelogram*.

Now the first two squares, consisting of two parts out of 8, they may each of them, by the eighth rank of the triangle, be taken 28 different ways, which makes

Combina-
tion.

makes 56. And the last two squares, consisting of four parts, may each be taken by the same rank of the triangle 70 times, which makes 140
To which add the foregoing number 56

And the number of the different squares that may be formed of the 8 triangles, will be 196

VII. A man has 12 different sorts of flowers, and a large number of each sort. He is desirous of setting them in beds or flourishes, in his parterre. Six flowers in some, 7 in others, and 8 in others; so as to have the greatest variety possible; the flowers in no two beds to be the same. To find how many beds he must have. 1. The combinations of 6 in 12 by the last rank of the triangle, are 924

2. The combinations of 7 in 12, are 792

3. The combinations of 8 in 12, are 495

Therefore the number of beds must be 2211

VIII. To find the number of chances that may be thrown on two dice. As each die has 6 faces, and as every face of one die may be combined with all the faces of the other, it follows, that 6 multiplied by 6, that is 36, will be the number of all the chances; as is also evident from the following table :

Points.	Numb. of chances.	Numb. of points.
2 1.1	1	2
3 2.1 1.2	2	6
4 2.2 3.1 1.3	3	12
5 4.1 1.4 3.2 2.3	4	20
6 3.3 5.1 1.5 4.2 2.4	5	30
7 6.1 1.6 5.2 2.5 4.3 3.4	6	42
8 4.4 6.2 2.6 5.3 3.5	5	40
9 6.3 3.6 5.4 4.5	4	36
10 5.5 6.4 4.6	3	30
11 6.5 5.6	2	22
12 6.6	1	12
	26	252

It appears by this table, 1. That the number of chances for each point continually increases to the point of seven, and then continually decreases till 12: therefore if two points are proposed to be thrown, the equality, or the advantage of one over the other, is clearly visible *. 2. The whole number of chances on the dice being 252, if that number be divided by 36, the number of different throws on the dice, the quotient is 7: it follows therefore, that at every throw there is an equal chance of bringing seven points. 3. As there are 36 chances on the dice, and only 6 of them doublets, it is 5 to 1, at any one throw, against throwing a doublet.

By the same method the number of chances upon any number of dice may be found: for if 36 be multiplied by 6, that product, which is 216, will be the chances on 3 dice; and if that number be multiplied by 6, the product will be the chances on 4 dice, &c.

COMBINATIONS of the Cards. The following experiments, founded on the doctrine of combinations, may possibly amuse a number of our readers. The tables given are the basis of many experiments, as well on numbers, letters, and other subjects, as on the cards; but the effect produced by them with the

Combina-
tion.

last is the most surprising, as that which should seem to prevent any collusion, that is, the shuffling of the cards, is on the contrary the cause from whence it proceeds.

It is a matter of indifference what numbers are made use of in forming these tables. We shall here confine ourselves to such as are applicable to the subsequent experiments. Any one may construct them in such manner as is agreeable to the purposes he intends they shall answer.

To make them, for example, correspond to the nine digits and a cipher, there must be ten cards, and at the top of nine of them must be wrote one of the digits, and on the tenth a cipher. These cards must be placed upon each other in the regular order, the number 1 being on the first, and the cipher at bottom. You then take the cards in your left hand, as is commonly done in shuffling, and taking off the two top cards, 1 and 2, you place the two following, 3 and 4, upon them; and under those four cards the three following 5, 6, and 7: at the top you put the cards 8 and 9, and at the bottom the card marked 0. Constantly placing in succession 2 at top and 3 at bottom, and they will then be in the following order :

8.9..3.4..1.2..5.6.7..0

If you shuffle them a second time, in the same manner, they will then stand in this order :

6.7..3.4..8.9..1.2.5..0

Thus, at every new shuffle, they will have a different order, as is expressed in the following lines :

1 shuffle 8.9.3.4.1.2.5.6.7.0
2 6.7.3.4.8.9.1.2.5.0
3 2.5.3.4.6.7.8.9.1.0
4 9.1.3.4.2.5.6.7.8.0
5 7.8.3.4.9.1.2.5.6.0
6 5.6.3.4.7.8.9.1.2.0
7 1.2.3.4.5.6.7.8.9.0

It is a remarkable property of this number, that the cards return to the order in which they were first placed, after a number of shuffles, which added to the number of columns that never change the order, is equal to the number of cards. Thus the number of shuffles is 7, and the number of columns in which the cards marked 3, 4, &c. never change their places is 3, which are equal to 10, the number of the cards. This property is not common to all numbers; the cards sometimes returning to the first order in less number, and sometimes in a greater number of shuffles than that of the cards.

TABLES OF COMBINATIONS, Constructed on the foregoing principles.

I. For ten numbers.

Order before dealing. After 1st deal. After the 2d. After the 3d.

1	8	6	2
2	9	7	5
3	3	3	3
4	4	4	4
5	1	8	6
6	2	9	7
7	5	1	8
8	6	2	9
9	7	5	1
0	0	0	0

These

* It is easy from hence to determine whether a bet proposed at hazard, or any other game with the dice, be advantageous or not; if the dice be true; (which, by the way, is rarely the case for any long time together, as it is so easy for those that are possessed of a dexterity of hand to change the true dice for false).

Combina-
tion.

These tables, and the following examples at piquet except the 36th, appear to have been compiled by M. Guyot.

II. For twenty-four numbers.

Order before dealing. After 1st deal. After the 2d. After the 3d.

1	23	21	17
2	24	22	20
3	18	12	2
4	19	15	7
5	13	5	13
6	14	6	14
7	8	9	3
8	9	3	18
9	3	18	12
10	4	19	15
11	1	23	21
12	2	24	22
13	5	13	5
14	6	14	6
15	7	8	9
16	10	4	19
17	11	1	23
18	12	2	24
19	15	7	8
20	16	10	4
21	17	11	1
22	20	16	10
23	21	17	11
24	22	20	16

III. For twenty-seven numbers.

Order before dealing. After 1st deal. After the 2d. After the 3d.

1	23	21	17
2	24	22	20
3	18	12	2
4	19	15	7
5	13	5	13
6	14	6	14
7	8	9	3
8	9	3	18
9	3	18	12
10	4	19	16
11	1	23	21
12	2	24	22
13	5	13	5
14	6	14	6
15	7	8	9
16	10	4	19
17	11	1	23
18	12	2	24
19	15	7	8
20	16	10	4
21	17	11	1
22	20	16	10
23	21	17	11
24	22	20	16
25	25	25	25
26	26	26	26
27	27	27	27

* These letters should be wrote in capitals on one of the corners of each card, that the words may be easily legible when the cards are spread open.

† For the same reason if you would have the answer after one shuffle, the cards must be placed according to the first column of the table; or if after three shuffles, according to the third column.

Combina-
tion.

IV. For thirty-two numbers.

Order before dealing. After 1st deal. After the 2d. After the 3d.

1	28	26	22
2	29	27	25
3	23	17	7
4	24	20	12
5	18	10	9
6	19	11	3
7	13	1	28
8	14	2	29
9	8	14	2
10	9	8	14
11	3	23	17
12	4	24	20
13	1	28	26
14	2	29	27
15	5	18	10
16	6	19	11
17	7	13	1
18	10	9	8
19	11	3	23
20	12	4	24
21	15	5	18
22	16	6	19
23	17	7	13
24	20	12	4
25	21	15	5
26	22	16	6
27	25	21	15
28	26	22	16
29	27	25	21
30	30	30	30
31	31	31	31
32	32	32	32

I. "Several letters that contain no meaning, being wrote upon cards, to make them, after they have been twice shuffled, give an answer to a question that shall be propoed; as for example, *What is love?*" Let 24 letters be wrote on as many cards, which, after they have been twice shuffled, shall give the following answer.

A dream of joy that soon is o'er.

First, write one of the letters in that line on each of the cards*. Then write the answer on a paper, and assign one of the 24 first numbers to each card, in the following order:

A D R E A M O F J O Y T H A T S O O N

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19

I S O ' E R.

20 21 22 23 24

Next, write on another paper a line of numbers, from 1 to 24, and looking in the table for 24 combinations you will see that the first number after the second shuffle is 21, therefore the card that has the first letter of the answer, which is A, must be placed against that number, in the line of numbers you have just made†. In like manner the number 22 being the second of the same column, indicates that the card which answers to the second letter D of the answer, must

must be placed against that number : and so of the rest. The cards will then stand in the following order :

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19
O O F S A M N T O I S R H A E O ' E J O
20 21 22 23 24
R A D Y T

From whence it follows, that after these cards have been twice shuffled, they must infallibly stand in the order of the letters in the answer.

Observe 1. You should have several questions, with their answers, consisting of 24 letters, wrote on cards: these cards should be put in cases, and numbered, that you may know to which question each answer belongs. You then present the questions; and when any one of them is chose, you pull out the case that contains the answer, and shewing that the letters wrote on them make no sense, you then shuffle them, and the answer becomes obvious.

2. To make this experiment the more extraordinary, you may have three cards, on each of which an answer is wrote; one of which cards must be a little wider, and another a little longer, than the others. You give these three cards to any one, and when he has privately chose one of them he gives you the other two other, which you put in your pocket without looking at them, having discovered by feeling which he has chose. You then pull out the case that contains the cards that answer to his question, and perform as before.

3. You may also contrive to have a long card at the bottom, after the second shuffle. The cards may be then cut several times, till you perceive by the touch that the long card is at bottom, and then give the answer; for the repeated cuttings, however often, will make no alteration in the order of the cards.

The second of these observations is applicable to some of the subsequent experiments, and the third may be practised in almost all experiments with the cards. You should take care to put up the cards as soon as the answer has been shewn: so that if any one should desire the experiment to be repeated, you may offer another question, and pull out those cards than contain the answer.

Though this experiment cannot fail of exciting at all times pleasure and surprize, yet it must be owned that a great part of the applause it receives arises from the address with which it is performed.

II. "The 24 letters of the alphabet being wrote upon so many cards, to shuffle them, and pronounce the letters shall then be in their natural order; but that not succeeding, to shuffle them a second time, and then shew them in proper order." Write the 24 letters on the cards in the following order :

1 2 3 4 5 6 7 8 9 10 11 12
R S H Q E F T P G U X C
13 14 15 16 17 18 19 20 21 22 23 24
N O D Y Z I K & A B L M

The cards being disposed in this manner, shew them upon the table, that it may appear they are promiscuously marked. Then shuffle and lay them again on the table, pronouncing that they will be then in alphabetical order. Appear to be surprised that you have failed; take them up again and give them a second shuffle, and then counting them down on the table they

will all be in their natural order.

III. "Several letters being wrote promiscuously upon 32 cards, after they have been once shuffled, to find in a part of them a question; and then shuffling the remainder a second time, to shew the answer. Suppose the question to be, *What is each Briton's boast?* and the answer, *His liberty*; which taken together contain 32 letters."

After you have wrote those letters on 32 cards, write on a paper the words *his liberty*, and annex to the letters the first ten numbers thus :

H I S L I B E R T Y
1 2 3 4 5 6 7 8 9 10

Then have recourse to the table of combinations for ten numbers, and apply the respective numbers to them in the same manner as in experiment I. taking the first column, as these are to be shuffled only once, according to that order.

1 2 3 4 5 6 7 8 9 10
I B S L E R T H I Y

This is the order in which these cards must stand after the whole number 32 has been once shuffled, so that after a second shuffle they may stand in their proper order. Next dispose the whole number of letters according to the first column for 32 letters: the last ten are to be here placed in the order above; as follows,

W H A T I S E A C H B R I T O N ' S
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17
B O A S T ?

18 19 20 21 22
I B S L E R T H I Y

Therefore, by the first column of the table, they will next stand thus :

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
I T B R O N S C H B O A E A S T l o n g c a r d .
17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32
I I S B S L I B E R T W H I Y

You must observe that the card here placed the 16th in order, being the last of the question, is a long card; that you may cut them, or have them cut, after the first shuffle, at that part, and by that means separate them from the other ten cards that contain the answer.

Your cards being thus disposed, you show that they make no meaning; then shuffle them once, and cutting them at the long card, you give the first part to any one, who reads the question, but can find no answer in the others, which you open before him; you then shuffle them a second time, and show the answer as above.

IV. "To write 32 letters on so many cards, then shuffle and deal them by twos to two persons, in such manner, that the cards of one shall contain a question, and those of the other, an answer. Suppose the question to be, *Is nothing certain?* and the answer, *Yes, disappointment.*"

Over the letters of this question and answer, write the following numbers, which correspond to the order in which the cards are to be dealt by two and two.

I S N O T H I N G C E R T A I N ?
31 32 27 28 23 24 19 20 15 16 11 12 7 8 3 4
Y E S , D I S A P O I N T M E N T .
29 30 25 26 21 22 17 18 13 14 9 10 5 6 1 2

Combina-
tion.

Then have recourse to the first column of the table for 32 numbers, and dispose these 32 cards in the following order, by that column.

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
O I E R G C A N T P I N T A I S
17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32
T M E H S D I N N O Y N T E I S

The cards being thus disposed, shuffle them once, and deal them two and two; when one of the parties will necessarily have the question, and the other the answer.

Instead of letters you may write words upon the 32 cards, 16 of which may contain a question, and the remainder the answer; or what other matter you please. If there be found difficulty in accommodating the words to the number of cards, there may be two or more letters or syllables wrote upon one card.

V. "The five beatitudes." The five blessings we will suppose to be, 1. Science, 2. Courage, 3. Health, 4. Riches, and 5. Virtue. These are to be found upon cards that you deal, one by one, to five persons. First write the letters of these words successively, in the order they stand, and then add the numbers here annexed to them.

S C I E N C E C O U R A G E
31 26 21 16 11 6 1 32 27 22 17 12 7 2
H E A L T H R I C H E S
28 23 18 13 8 3 29 24 19 14 9 4
V I R T U E
30 25 20 15 10 5

Then range them in order agreeable to the first column of the table for 32 numbers, as in the last experiment. Thus,

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
L H N A T E R E U A C R G T I U
17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32
E C I I C H S O H R E V S C

Next, take a pack of cards, and write on the four first the word Science; on the four next the word Courage and so of the rest.

Matters being thus prepared, you show that the cards on which the letters are wrote convey no meaning. Then take the pack on which the words are wrote, and spreading open the first four cards, with their backs upward, you desire the first person to choose one. Then close those cards and spread the next four to the second person; and so to all the five; telling them to hold up their cards lest you should have a confederate in the room.

You then shuffle the cards, and deal them one by one, in the common order, beginning with the person who chose the first card, and each one will find in his hand the same word as is wrote on his card. You will observe, that after the sixth round of dealing, there will be two cards left, which you give to the first and second persons, as their words contain a letter more than the others.

VI. "The cards of the game of piquet being mixed together, after shuffling them, to bring, by cutting them, all the cards of each suit together." The order in which the cards must be placed to produce the effect desired being established on the same principle as that explained in the experiment II. except that the shuf-

fling is here to be repeated three times, we think it will be sufficient to give the order in which they are to be placed before the first shuffle.

Combina-
tion.

Order of the Cards.

1 Ace	} clubs	17 King clubs
2 Knave		18 Ten
3 Eight	} diamonds	19 Nine } hearts
4 Seven		20 Seven clubs
wide card		
5 Ten clubs		21 Ace diamonds
6 Eight	} spades	22 Knave spades
7 Seven		23 Queen hearts
wide card		
8 Ten		24 Knave hearts
9 Nine	} diamonds	25 Ace spades
10 Queen		26 King diamonds
11 Knave		27 Nine clubs
12 Queen clubs		28 Ace } hearts
13 Eight	} hearts	29 King
14 Seven		30 Eight clubs
wide card		
15 Ten	} spades	31 King
16 Nine		32 Queen

You then shuffle the cards, and cutting at the wide card, which will be the seven of hearts, you lay the eight cards that are cut, which will be the suit of hearts, down on the table. Then shuffling the remaining cards a second time, you cut at the second wide card, which will be the seven of spades, and lay, in like manner, the eight spades down on the table. You shuffle the cards a third time, and offering them to any one to cut, he will naturally cut them at the wide card*, which is the seven of diamonds, and consequently divide the remaining cards into two equal parts, one of which will be diamonds and the other clubs.

VII. "The cards at piquet being all mixed together, to divide the pack into two unequal parts, and name "the number of points contained in each part." You are first to agree that each king, queen, and knave shall count, as usual, 10, the ace 1, and the other cards according to the number of the points. Then dispose the cards, by the table for 32 numbers, in the following order, and observe that the last card of the first division must be a wide card.

Order of the cards before shuffling.

1 Seven hearts	17 Nine diamonds
2 Nine clubs	18 Ace spades
3 Eight hearts	19 Ten clubs
4 Eight	20 Knave
5 Knave	} spades
6 Ten	
7 Queen	} clubs
8 Ace	
9 Ace hearts	} diamonds
wide card	
10 Nine hearts	26 Knave hearts
11 Queen spades	27 King clubs
12 Knave clubs	28 Nine } spades
13 Ten diamonds	29 King
14 Ten	30 Ace diamonds
15 King	} hearts
16 Queen	
	31 Seven
	32 Eight } clubs

You

* You must take particular notice whether they be cut at the wide card, and if they are not, you must have them cut, or cut them again yourself.

Combina-
tion.

You then shuffle them carefully, according to the method before described, and they will stand in the following order.

Cards.	Numbers.	Cards.	Numbers.
		brought up	34
1 Nine	9	6 Ten clubs	10
2 King	10	7 Ten diamonds	10
3 Seven	7	8 Ten hearts	10
4 Seven diamonds	7	9 Ace clubs	1
5 Ace spades	1	10 Ace hearts (wide card)	1
carried up	34	total	66
		Brought up	101
11 Eight hearts	8	22 Queen hearts	10
12 Eight spades	8	23 Nine	9
13 Seven hearts	7	24 Knave	8
14 Nine clubs	9	25 Eight	8
15 Knave	10	26 King	10
16 Ten	10	27 Queen	10
17 Queen clubs	10	28 Knave hearts	10
18 Nine hearts	9	29 King clubs	10
19 Queen spades	10	30 Ace diamonds	1
20 Knave clubs	10	31 Seven	7
21 King hearts	10	32 Eight	8
carried up	101	total	194

When the cards are by shuffling disposed in this order, you cut them at the wide card, and pronounce that the cards you have cut off contain 66 points, and consequently the remaining part 194.

VIII. "The Inconceivable Repique *." When you would perform this experiment with the cards used in the last, you must observe not to disorder the first 10 cards, in laying them down on the table. Putting those cards together, in their proper order, therefore, you shuffle them a second time in the same manner, and offer them to any one to cut, observing carefully if he cut them at the wide card, which will be the ace of hearts, and will then be at top; if not, you must make him, under some pretence or other, cut them till it is; and the cards will then be ranged in such order that you will repique the person against whom you play, though you let him choose (even after he has cut) in what suit you shall make the repique.

Order of the cards after they have been shuffled and cut.

1 Eight hearts	17 Nine	diamonds
2 Eight	18 Knave	diamonds
3 Knave	19 Nine hearts	
4 Ten	20 Queen spades	
5 Queen	21 Seven hearts	
6 Knave	22 Nine clubs	
7 King	23 Ten hearts	
8 Queen	24 Ace clubs	
9 Eight	25 Seven spades	
10 King	26 Seven diamonds	
11 Queen	27 Nine spades	
12 Ace	28 King	spades
13 Seven	29 Ace	spades
14 Eight	30 Ten clubs	
15 Knave hearts	31 Ten diamonds	
16 King clubs	32 Ace hearts (wide card)	

VOL. III.

Combina-
tion

The cards being thus disposed, you ask your adversary in what suit you shall repique him. If he say in clubs or diamonds, you must deal the cards by threes, and the hands will be as follows,

Elder.	Younger.
Hearts, king	Clubs, ace
— queen	— king
— knave	— queen
— nine	— knave
— eight	— nine
— seven	Diamonds, ace
Spades, queen	— king
— knave	— queen
— eight	— knave
Diamonds, eight	— nine
Clubs, eight	Spades, ten
— seven	Hearts, ten
Rentrée, or take in of the elder.	Rentrée of the younger.
Seven spades	Ten clubs
Seven diamonds	Ten diamonds
Nine	Ace hearts
King	
spades	
Ace	

If he against whom you play, who is supposed to be elder hand, has named clubs for the repique, and has taken in five cards, you must then lay out the queen, knave, and nine of diamonds, and you will have, with the three cards you take in, a sixiem major in clubs, and quatorze tens. If he leave one or two cards, you must discard all the diamonds.

If he require to be repiqued in diamonds, then discard the queen, knave, and nine of clubs; or all the clubs, if he leave two cards; and you will then have a hand of the same strength as before.

Note, If the adversary should discard five of his hearts, you will not repique him, as he will then have a septiem in spades: or if he only take one card: but neither of these any one can do, who has the least knowledge of the game. If the person against whom you play would be repiqued in hearts or spades, you must deal the cards by twos, and the game will stand thus:

Elder hand.	Younger hand.
King	Ace
Knave	King
Nine	— clubs
Eight	Ace
Queen	— diamonds
Knave	Queen
Nine	— spades
Eight	Knave
Seven	Ten
Eight	King
Seven	Queen
Eight spades	— hearts
Rentrée.	Knave
Seven spades	Ten
Seven diamonds	—
Nine	—
King	—
spades	—
Ace	—

12 M

If

* This manœuvre of piquet was invented by the countess of L— (a French lady) and communicated by her to M. Guyot.

Combina-
tion.

If he require to be repiqued in hearts, you keep the quint to a king in hearts, and the ten of spades, and lay out which of the rest you please : then, even if he should leave two cards, you will have a fixiem major in hearts, and quatorze tens, which will make a repique.

But if he demand to be repiqued in spades : at the end of the deal you must dexterously pass the three cards that are at the bottom of the stock (that is, the ten of clubs, ten of diamonds, and ace of hearts) to the top*, and by that means you reserve the nine, king, and ace of spades for yourself : so that by keeping the quint in hearts, though you should be obliged to lay out four-cards, you will have a fixiem to a king in spades, with which and the quint in hearts, you must make a repique.

Observe here likewise, that if the adversary lay out only three cards, you will not make the repique : but that he will never do, unless he be quite ignorant of the game, or has some knowledge of your intention.

This last stroke of piquet has gained great applause, when those that have publicly performed it have known how to conduct it dexterously. Many persons who understand the nature of combining the cards, have gone as far as the passing the three cards from the bottom of the stock, and have then been forced to confess their ignorance of the manner in which it was performed.

IX. "The Metamorphosed Cards." Provide 32 cards that are differently coloured ; on which several different words are wrote, and different objects painted. These cards are to be dealt two and two, to four persons, and at three different times, shuffling them each time. After the first deal, every one's cards are to be of the same colour ; after the second deal, they are all to have objects that are similar ; and after the third, words that convey a sentiment.

Dispose of the cards in the following order.

Order of the cards.	Colours.	Objects.	Words.
1	Yellow	Bird	I find
2	Yellow	Bird	In you
3	Green	Flower	Charming
4	Green	Flower	Flowers
5	White	Bird	To hear
6	White	Orange	Beauty
7	Red	Butterfly	My
8	Red	Flower	Notes
9	Red	Flower	In
10	Red	Butterfly	Shepherdes
11	Green	Butterfly	Lover
12	Green	Butterfly	Your
13	White	Flower	Of
14	White	Flower	an inconstant
15	Yellow	Orange	Image
16	Yellow	Flower	Enchanting
17	White	Orange	Ardour
18	Yellow	Butterfly	My
19	Yellow	Butterfly	Phyllis.
20	White	Bird	Birds
21	Red	Orange	Sing
22	Red	Orange	Dear

23	Green	Orange	and sweetness	Combina- tion
24	Green	Orange	The	Comber.
25	Green	Bird	Of	
26	Green	Bird	Present	
27	Yellow	Flower	As	
28	Red	Bird	Changes	
29	Red	Bird	Bottom	
30	Yellow	Orange	Me	
31	White	Butterfly	Your	
32	White	Butterfly	I long	

The cards thus coloured, figured, and transcribed, are to be put in a case, in the order they here stand.

When you would perform this experiment you take the cards out of the case, and show, without changing the order in which they were put, that the colours, objects, and words are all placed promiscuously. You then shuffle them in the same manner as before, and deal them, two and two, to four persons, observing that they do not take up their cards till all are dealt, nor mix them together : and the eight cards dealt to each person will be found all of one colour. You then take each person's cards, and put those of the second person under those of the first, and those of the fourth person under those of the third. After which you shuffle them a second time, and having dealt them in the same manner, on the first person's cards will be painted all the birds ; on the second person's cards, all the butterflies ; on those of the third, the oranges ; and on those of the fourth, the flowers. You take the cards a second time, and observing the same precautions, shuffle and deal them as before, and then the first person, who had the last time the birds in his hand, will have the words that compose this sentence. *Sing, dear birds ; I long to hear your enchanting notes.*

The second person, who the last deal had the butterflies, will now have these words :

Of an inconstant lover your changes present me the image.

The third, who had the oranges, will have this sentence :

As in my Phyllis, I find in you beauty and sweetness.

The fourth, who had the flowers, will have these words :

Charming flowers, adorn the bosom of my shepherdess.

It seems quite unnecessary to give any further detail, as they who understand the foregoing experiments will easily perform this.

Among the different purposes to which the doctrine of combinations may be applied, those of writing in cipher, and deciphering, hold a principal place. See the article CIPHER.

COMBINATION, in chemistry, signifies the union of two bodies of different natures, from which a new compound body results. For example, when an acid is united with an alkali, we say that a combination betwixt these two saline substances takes place ; because from this union a neutral salt results, which is composed of an acid and an alkali.

COMBER, or CUMBER (Thomas), an eminent divine born at Westram in Kent, in 1645, was educated at Cambridge ;

* The manner of doing this is explained in the article LEGERDEMAIN.

Combustion
↓
Comedy.

Cambridge; created doctor of divinity; and, after several preferments in the church, was made dean of Durham. He was chaplain to Anne princess of Denmark, and to king William and queen Mary. He was author of several works, *viz.* 1. A scholastical history of the primitive and general use of Liturgies. 2. A Companion to the Altar. 3. A brief discourse upon the offices of baptism, catechism, and confirmation. He died in 1699, aged 55.

COMBUSTION, is the dissipation of the inflammable principle of any body by means of fire, whether this dissipation is attended with actual flame or not. See FLAME, and IGNITION.

COMEDY, a sort of dramatic poetry, which gives a view of common and private life, recommends virtue, and exposes the vices and follies of mankind in an humorous and merry way. Scaliger defines comedy a dramatic poem, representing the business of life, whose event is fortunate and still familiar. Vossius defines it a dramatic poem, copying the actions of the principal citizens and common people in a familiar stile, and not without mirth and raillery.

Critics are much divided about the nature of comedy. Aristotle calls it an imitation of the worst, or rather, of the lowest, class of persons, by way of ridicule. Mr Cornelle finds fault with this, and maintains, that the actions of kings themselves may enter comedy, provided they be such as are not very momentous, unattended with any considerable danger. Mr Congreve seems pretty much of the same sentiment: but Mr Dacier is of a contrary opinion: he maintains, that comedy allows of nothing grave or serious, unless it be turned to ridicule; and that raillery and ridicule are its only proper and genuine marks. Thus different are critics on the nature of comedy: nor are they better agreed concerning the characteristic which distinguishes it from tragedy. Some distinguish it by the lowliness of the subject; others by the ridiculous light it is set in. According to F. Bosfu, comedy differs from tragedy in this, that the comic writer invents both the names of his persons, and the action which he presents; whereas the tragic writers invent only the latter; the former they are to take from history.

Comedy has parts of quality and parts of quantity. Of the first kind there are four essential, the fable, the manners, the sentiments, and the diction; to which two are added, which only relate to the representation, *viz.* the music and decoration. See FABLE, MANNERS, &c.

The parts of quantity are also four. 1. The entrance. 2. The working up of the plot. 3. The full growth of the plot, or the counter-turn. 4. The discovery, or unravelling of the plot. These, in the language of the ancients, are called the *protasis*, *epitasis*, *catastasis*, and *catastrophe*. See the articles *PROTASIS*, *EPITASIS*, *ACT*, &c.

With regard to the various revolutions comedy has undergone, it is commonly distinguished into three kinds, *viz.* the ancient, the middle, and the new. The ancient comedy was sharp, satirical, and extremely abusive; even men of the first rank, if they were suspected of any criminal behaviour, whether the facts were true or false, were brought upon the

stage without any disguise, called by their own names, and used as severely as possible. Thus in the comedy of the Clouds, Aristophanes brings Socrates in by name. Indeed this liberty of abuse was allowed chiefly to the chorus, and was most used during the democracy of the Athenians, especially in the time of the Peloponnesian war. But when the thirty tyrants had seized the government, the middle comedy commenced; for it being no longer safe for the poets to rail at people in authority, and openly to charge magistrates with crimes, they still continued to ridicule the follies, and expose the vices of particular persons under fictitious names; by which the persons were so well pointed out, that it was no difficult matter to know them. At length, however, they were obliged, in the reign of Alexander the Great, to repress even this license; and this reformation gave occasion to the new comedy, which only brought upon the stage feigned adventures and imaginary names.

This last kind alone was received among the Romans, who nevertheless made a new subdivision of it into ancient, middle, and new, according to the various periods of the commonwealth. Among the ancient comedies were reckoned those of Livius Andronicus; among the middle those of Pacuvius; and among the new ones, those of Terence. They likewise distinguished comedy according to the quality of the persons represented, and the dress they wore, into *togata*, *prætextata*, *trabeata*, and *tabernaria*, which last agrees pretty nearly with our farces. Among us, comedy is distinguished from farce, as the former represents nature as she is; the other distorts and overcharges her. They both paint from the life, but with different views: the one to make nature known, the other to make her ridiculous.

COMENIUS (John Amos), a grammarian and Protestant divine, born in Moravia in 1592. He was eminent for his design to introduce in a new method of teaching languages; for which purpose he published some essays in 1616, and had prepared some others, when the Spaniards pillaged his library, after having taken the city of Fulneck, where he was minister and master of the school. Comenius fled to Lesna, a city of Poland, and taught Latin there. The book he published in 1631, under the title of *Janua Linguarum restructa*, gained him a prodigious reputation, inasmuch that he was offered a commission for regulating all the schools in Poland. The parliament of England desired his assistance to regulate the schools in that kingdom. He arrived at London in 1641; and would have been received by a committee to hear his plan, had not the parliament been taken up with other matters. He therefore went to Sweden, being invited by a generous patron, who settled a stipend upon him that delivered him from the fatigues of teaching; and now he employed himself wholly in discovering general methods for those who instructed youth. In 1657 he published the different parts of his new method of teaching. He was not only taken up with the reformation of schools, but he also filled his brain with prophecies, the fall of antichrist, Millennium, &c. At last Comenius took it into his head to address Lewis XIV. of France, and to send him a copy of the prophecies of Drabicius; insinuating that it was to the

Comitia.

monarch God promised the empire of the world. He became sensible at last of the vanity of his labours, and died in 1671.

COMET, an opaque, spherical, and solid body like a planet, performing revolutions about the sun in elliptical orbits, which have the sun in one of their foci.

There is a popular division of comets into *tailed*, *bearded*, and *hairy* comets: though this division rather relates to the different circumstances of the same comet, than to the phenomena of several. Thus when the light is westward of the sun, and sets after it, the comet is said to be *tailed*, because the train follows it in the manner of a tail: when the comet is eastward of the sun, and moves from it, the comet is said to be *bearded*, because the light marches before it in the manner of a beard. Lastly, when the comet and the sun are diametrically opposite, (the earth between them), the train is hid behind the body of the comet, except a little that appears round it in form of a border of *hair*: and from this last appearance the word comet is derived; as *κομήτης*, *comēta*, comes from *κομῆναι*, *coma*, hair. But there have been comets whose disk was as clear, as round, and as well defined, as that of Jupiter, without either tail, beard, or coma. See ASTRONOMY, n° 7. 46.—64. where the nature and phenomena of comets are fully explained.

COMETARIUM, a curious machine, exhibiting an idea of the revolution of a comet about the sun. See ASTRONOMY, n° 318. and Plate LII. fig. 2.

COMETEAN, a town of Bohemia in the circle of Saltz, with a handsome town house. It was taken by storm in 1421, and all the inhabitants, men, women, and children, put to the sword. It is seated in a fertile plain, in E. Long. 13. 25. N. Lat. 50. 30.

COMINES (Philip de), an excellent historian, born of a noble family in Flanders, in 1446. He lived in a kind of intimacy with Charles the Bold, duke of Burgundy, for about eight years; but being seduced to the court of France by Lewis XI. he was highly promoted by him, and executed several successful negotiations. After this king's death he experienced many troubles on account of being a foreigner, by the envy of other courtiers, and lay long in prison before he was discharged: he died in 1509. Comines was a man of more natural abilities than learning; he spoke several living, but knew nothing of the dead languages: he has left behind him some memoirs of his own times, that are admired by all true judges of history. Catherine de Medicis used to say, that Comines made as many heretics in politics, as Luther had in religion.

COMINES, a town of French Flanders on the lines which the French have made to defend their country against the Austrian Netherlands. It is situated on the river Lis, in E. Long. 3. 1. N. Lat. 50. 30.

COMITIA, in Roman antiquity, were general assemblies of the people, lawfully called by some magistrate for the enjoyment or prohibition of any thing by their votes.

The proper comitia were of three sorts; *curiata*, *centuriata*, and *tributa*; with reference to the three grand divisions of the city and people into *curiæ*, *centuriæ*, and *tribes*: For, by comitia *calata*, which we sometimes meet with in authors, in elder times were

meant all the comitia in general; the word *calata* from *καλέω*, or *calo*, being their common epithet; though it was at last restrained to two sorts of assemblies, those for the creation of priests, and those for the regulation of last-wills and testaments.

The *comitia curiata* owe their origin to the division which Romulus made of the people into 30 *curiæ*; ten being contained in every tribe. They answered in most respects to the parishes in our cities, being not only separated by proper bounds and limits, but distinguished too by their different places set apart for the celebration of divine service, which was performed by particular priests, (one to every *curia*), with the name of *curiones*.

Before the institution of the comitia centuriata, all the grand concerns of the state were transacted in the assembly of the *curiæ*; as the election of kings and other chief officers, the making and abrogating of laws, and the judging of capital causes. After the expulsion of the kings, when the commons had obtained the privilege to have tribunes and ædiles, they elected them for some time at these assemblies; but that ceremony being at length transferred to the comitia tributa, the *curiæ* were never convened to give their votes, except now and then upon account of making some particular law relating to adoptions, wills, and testaments, or the creation of officers for an expedition; or for the electing some of the priests, as the *flamines*, and the *curio maximus*, or superintendent of the *curiones*, who were themselves chosen by every particular *curia*.

The power of calling these assemblies belonged at first only to the kings; but upon the establishment of the democracy, the same privilege was allowed to most of the chief magistrates, and sometimes to the pontifices.

The persons who had the liberty of voting here were such Roman citizens as belonged to the *curiæ*; or such as actually lived in the city, and conformed to the customs and rites of their proper *curiæ*; all those being excluded who dwelt without the bounds of the city, retaining the ceremonies of their own country, though they had been honoured with the *jus civitatis*, or admitted free citizens of Rome. The place where the curia met was the *comitium*, a part of the forum: No set time was appointed for the holding these, or any other of the comitia, but only as business required.

The people being met together, and confirmed by the report of good omens from the augurs, (which was necessary in all the assemblies), the rogatio, or business to be proposed to them, was publicly read. After this, (if none of the magistrates interposed), upon the order of him that presided in the comitia, the people divided into their proper *curiæ*, and consulted of the matter; and then the *curiæ* being called out, as it happened by lot, gave their votes man by man, in ancient times *viva voce*, and afterwards by tablets; the most votes in every *curia* going for the voice of the whole *curia*, and the most *curiæ* for the general consent of the people.

In the time of Cicero, the comitia curiata were so much out of fashion, that they were formed only by 30 lictors representing the 30 *curiæ*; whence, in his second

Comitia. Second oration against Rullus, he calls them *comitia aduimbrata*.

Comitia.

The *comitia centuriata* were instituted by Servius Tullius: who, obliging every one to give a true account of what he was worth, according to those accounts, divided the people into six ranks or classes, which he subdivided into 193 centuries. The first class, containing the equites and richest citizens, consisted of 98 centuries. The second, taking in the tradesmen and mechanics, consisted of 22 centuries. The third, 20. The fourth, 22. The fifth, 30. The sixth, filled up with the poorer sort, but one century: and this, though it had the same name with the rest, yet was seldom regarded, or allowed any power in public matters. Hence it is a common thing with the Roman authors, when they speak of the classes, to reckon no more than five, the sixth not being worth their notice. This last class or order was divided into two parts, or orders; the *proletarii*, and the *capite censi*. The former, as their name implies, were designed purely to stock the republic with men, since they could supply it with so little money; and the latter, who paid the lowest tax of all, were rather counted and marshalled by their heads, than by their estates.

Persons of the first rank, by reason of their pre-eminence, had the name of *classici*; whence came the name of *classici auctores*, for the most approved writers. All others, of what classis soever, were said to be *infra classem*. The assembly of the people by centuries, was held for the electing of consuls, censors, and prætors; as also for the judging of persons accused of what they called *crimen perduellionis*, or actions by which the party had shewed himself an enemy to the state, and for the confirmation of all such laws as were proposed by the chief magistrates, who had the privilege of calling these assemblies.

The place appointed for their meeting was the *campus martius*; because in the primitive times of the commonwealth, when they were under continual apprehensions of enemies, the people, to prevent any sudden assault, went armed, in martial order, to hold these assemblies; and were for that reason forbid by the laws to meet in the city, because an army was upon no account to be marshalled within the walls: yet, in latter ages, it was thought sufficient to place a body of soldiers as a guard in the janiculum, where an imperial standard was erected, the taking down of which denoted the conclusion of the comitia.

Though the time of holding these comitia for other matters was undetermined; yet the magistrates, after the year of the city 601, when they began to enter on their place, on the kalends of January, were constantly *designati* about the end of July, and the beginning of August.

All the time between their election and confirmation they continued as private persons, that inquiry might be made into the election, and the other candidates might have time to enter objections, if they met with any suspicion of foul dealing. Yet, at the election of the censors, this custom did not hold; but as soon as they were elected, they were immediately invested with the honour.

By the institution of these comitia, Servius Tullius

secretly conveyed the whole of the power from the commons: for the centuries of the first and richest class being called out first, who were three more in number than all the rest put together, if they all agreed, as generally they did, the business was already decided, and the other classes were needless and insignificant. However, the three last scarce ever came to vote.

The commons, in the time of the free state, to remedy this disadvantage, obtained, that before they proceeded to voting any matter at these comitia, that century should give their suffrages first upon whom it fell by lot, with the name of *centuria prerogativa*; the rest being to follow according to the order of their classes. After the constitution of the 35 tribes into which the classes and their centuries were divided, in the first place, the tribes cast lots, which should be the *prerogative tribe*; and then the centuries of the tribes for the honour of being a prerogative century. All the other tribes and centuries had the appellation of *jure vocata*, because they were called out according to their proper places.

The prerogative century being chosen by lot, the chief magistrate, sitting in a tent in the middle of the *campus martius*, ordered that century to come out and give their voices; upon which they presently separated from the rest of the multitude, and came into an inclosed apartment, which they termed *septa*, or *ovilia*, passing over the *pontes* or narrow boards laid there for the occasion; on which account, *de ponte deici* signifies to be denied the privilege of voting, and persons thus dealt with are called *d. pontani*.

At the higher end of the *pontes* stood the *diribitores*, (a sort of under officers so called from their marshalling the people), and delivered to every man, in the election of magistrates, as many tablets as there appeared candidates, one of whose names was written upon every tablet. A proper number of great chests were set ready in the *septa*, and every body threw in which tablet he pleased.

By the chests were placed some of the public servants, who taking out the tablets of every century, for every tablet, made a prick or a point in another tablet which they kept by them. Thus, the business being decided by moist points, gave occasion to the phrase *omne tulit punctum*, and the like.

The same method was observed in the judiciary process at these comitia, and in the confirmation of laws; except that, in both these cases, only two tablets were offered to every person, on one of which was written U. R. and on the other A, in capital letters; the two first standing for *uti rogatus* "be it as you desire," relating to the magistrate who proposed the question; and the last for *utique*, or "I forbid it."

It is remarkable, that though in the election of magistrates, and in the ratification of laws, the votes of that century, whose tablets were equally divided, signified nothing; yet in trials of life and death, if the tablets *pro* and *con* were the same in number, the person was actually acquitted.

The division of people into tribes was an invention of Romulus, after he had admitted the Sabines into Rome; and though he constituted at that time only three, yet as the state encreased in power, and the city

Comitia
||
Comma.

city in number of inhabitants, they rose by degrees to 35. For a long time after this institution, a *tribe* signified no more than such a space of ground with its inhabitants. But at last the matter was quite altered, and a tribe was no longer *pars urbis*, but *civitatis*; not a quarter of the city, but a company of citizens living where they pleased. This change was chiefly occasioned by the original difference between the tribes in point of honour. For Romulus having committed all sordid and mechanic arts to the care of strangers, slaves, and libertines; and reserved the more honest labour of agriculture to the freemen and citizens, who by this active course of life might be prepared for martial service; the *tribus rusticae* were for this reason esteemed more honourable than the *tribus urbanae*. And now all persons being desirous of getting into the more creditable division; and there being several ways of accomplishing their wishes, as by adoption, by the power of censors, or the like; that rustic tribe which had the most worthy names in its roll, had the preference to all others, though of the same general denomination. Hence all of the same great family, bringing themselves by degrees into the same tribe, gave the name of their family to the tribe they honoured; whereas at first the generality of the tribes did not borrow their names from persons but from places.

The first assembly of the tribes we meet with is about the year of Rome 263, convened by Sp. Sicius, tribune of the commons, upon account of the trial of Coriolanus. Soon after, the tribes of the commons were ordered to be elected here; and at last, all the inferior magistrates, and the collegiate priests. The same comitia served for the enacting of laws relating to war and peace, and all others proposed by the tribunes and plebeian officers, though they had not properly the name of *leges* but *plebiscita*. They were generally convened by the tribunes of the commons; but the same privilege was allowed to all the chief magistrates. They were confined to no place; and therefore sometimes we find them held in the comitium, sometimes in the campus martius, and now and then in the capitol. The proceedings were in most respects answerable to those already described in the account of the other comitia, and therefore need not be insisted on. Only we may farther observe of the comitia in general, that when any candidate was found to have most tables for a magistracy, he was declared to be *designatus* or elected by the president of the assembly; and this they termed *renunciari consul, praetor*, or the like: and that the last sort of the comitia only could be held without the consent and approbation of the senate, which was necessary to the convening of the other two.

COMITIALIS MORBUS, an appellation given to the EPILEPSY, by reason the comitia of ancient Rome were dissolved if any person in the assembly happened to be taken with this distemper.

COMITIUM, in Roman antiquity, a large hall in the forum, where the COMITIA were ordinarily held.

COMMA, among grammarians, a point or character marked thus (,) serving to denote a short stop, and to divide the members of a period. Different authors define and use it differently. According to F.

Comma
||
Commandry.

Buffier, the comma serves to distinguish the members of a period, in each of which is a verb and the nominative case of the verb: thus, "That so many people are pleased with trifles, is owing to a weakness of mind, which makes them love things easy to be comprehended." Besides this, the comma is used to distinguish in the same member of a period, several nouns-substantive, or nouns-adjective, or verbs not united by a conjunction: thus, "Virtue, wit, knowledge, are the chief advantages of a man:" or, "A man never becomes learned without studying constantly, methodically, with a gust, application, &c." If those words are united in the same phrase with a conjunction, the comma is omitted; thus, "The imagination and the judgment do not always agree."

The ingenious author of the tract *De ratione interpungendi*, printed with Vossius's Element. Rhetor. Lond. 1724, lays down the use of a comma to be, to distinguish the simple members of a period or sentence; i. e. such as only consist of one subject, and one definite verb. But this rule does not go throughout; the same author instancing many particular cases not yet included herein, where yet the comma is advisable. See PUNCTUATION.

It is a general rule that a comma ought not to come between a nominative and a verb, or an adjective and substantive, when these are not otherwise disjoined: thus, in the sentence, *God ruleth with infinite wisdom*, a comma between *God* and *ruleth*, or between *infinite* and *wisdom*, would be absurd. But to this exceptions may occur; as when not a single word, but a sentence, happens to be the nominative: thus in the example first above given, where the sentence *that so many people are pleased with trifles*, forms the nominative to the verb *is*, a comma at trifles is proper, both for the sake of perspicuity, and as coinciding with a slight natural pause.

COMMA, in music. See INTERVAL.

COMMANDINUS (Frederic), born at Urbino in Italy, and descended from a very noble family, in the 16th century. To a vast skill in the mathematics, he had added a great knowledge in the Greek tongue, by which he was well qualified to translate the Greek mathematicians into Latin: accordingly he translated and published several, which no writer till then had attempted; as Archimedes, Apollonius, Euclid, &c.

COMMANDRY, a kind of benefice or fixed revenue belonging to a military order, and conferred on ancient knights who had done considerable services to the order.

There are strict or regular commandries, obtained in order, and by merit; there are others of grace and favour, conferred at the pleasure of the grand master. There are also commandries for the religious, in the orders of St Bernard and St Anthony. The kings of France have converted several of the hospitals for lepers into commandries of the order of St Lazarus.

The commandries of Malta are of different kinds; for as the order consists of knights, chaplains, and brothers-servitors, there are peculiar commandries or revenues attached to each. The knight to whom one of these benefices or commandries is given, is called *commander*: which agrees pretty nearly with the præpositus

Commelinæ præpositus set over the monks in places at a distance from the monastery, whose administration was called *obedientia*; because depending entirely upon the abbot who gave him his commission. Thus it is with the simple commanders of Malta, who are rather farmers of the order than beneficiaries; paying a certain tribute or rent, called *responsio*, to the common treasure of the order.

COMMELINA, in botany, a genus of the monogynia order, belonging to the triandria class of plants. There are 10 species, all of them natives of warm climates. They are herbaceous plants, rising from two to four feet high, and adorned with blue or yellow flowers. Their culture differs in nothing from that of the common exotics.

COMMEMORATION, in a general sense, the remembrance of any person or thing, or the doing any thing to the honour of a person's memory, or in remembrance of any past event. Thus, the eucharist is a commemoration of the sufferings of Jesus Christ.

COMMENDAM, in the ecclesiastical law, the trust or administration of the revenues of a benefice, given either to a layman, to hold by way of depositum for six months, in order to repairs, &c. or to an ecclesiastic or beneficed person, to perform the pastoral duties thereof, till once the benefice is provided with a regular incumbent.

Anciently, the administration of vacant bishoprics belonged to the nearest neighbouring bishop; which is still practised between the archbishopric of Lyons, and the bishopric of Autun: on this account they were called *commendatory bishops*.

This custom appears to be very ancient. S. Athanasius says of himself, according to Nicephorus, that there had been given him in *commendam*, i. e. in administration, another church besides that of Alexandria whereof he was stated bishop.

The care of churches, it seems, which had no pastor, was committed to a bishop, till they were provided of an ordinary: the register of pope Gregory I. is full of these commissions, or *commendams*, granted during the absence or sickness of a bishop, or the vacancy of the see.

Some say, that pope Leo IV. first set the modern *commendams* on foot, in favour of ecclesiastics who had been expelled their benefices by the Saracens; to whom the administration of the vacant churches was committed for a time, in expectation of their being restored: though S. Gregory is said to have used the same, while the Lombards desolated Italy.

In a little time the practice of *commendams* was exceedingly abused; and the revenues of monasteries

given to laymen for their subsistence. The bishops also procured several benefices, or even bishoprics, in *commendam*, which served as a pretext for holding them all without directly violating the canons. Part of the abuse has been retrenched; but the use of *commendams* is still retained, as an expedient to take off the incompatibility of the person by the nature of the benefice.

When a parson is made bishop, his parsonage becomes vacant; but if the king give him power, he may still hold it in *commendam*.

COMMENDATUS, one who lives under the protection of a great man. *Commendati homines*, were persons who, by voluntary homage, put themselves under the protection of any superior lord: for ancient homage was either *predial*, due for some tenure; or *personal*, which was by compulsion, as a sign of necessary subjection; or voluntary, with a desire of protection: and those who, by voluntary homage, put themselves under the protection of any men of power, were sometimes called *homines ejus commendati*, as often occurs in Domesday. *Commendati dimidii*, were those who depended on two several lords, and paid one-half of their homage to each; and *sub-commendati* were like under-tenants under the command of persons that were themselves under the command of some superior lord: also there were *dimidii sub-commendati*, who bore a double relation to such depending lords. This phrase seems to be still in use, in the usual compliment, "Commend me to such a friend," &c. which is to let him know, "I am his humble servant."

COMMENSURABLE, among geometricians, an appellation given to such quantities as are measured by one and the same common measure.

COMMENSURABLE Numbers, whether integers or fractions, are such as can be measured or divided by some other number without any remainder: such are 12 and 18, as being measured by 6 and 3.

COMMENSURABLE in Power, is said of right lines, when their squares are measured by one and the same space or superficies.

COMMENSURABLE Surds, those that being reduced to their least terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational one.

COMMENTARY, or **COMMENT**, in matters of literature, an illustration of the difficult or obscure passages of an author.

COMMENTARY, or **COMMENTARIES**, likewise denotes a kind of history, or memoirs of certain transactions, wherein the author had a considerable hand: such are the commentaries of Cæsar.

Commendatus
†
Commentary.

C O M M E R C E,

CHAP. I. HISTORY of COMMERCE.

§ i. General History.

IS an operation by which the wealth, or work, either of individuals or of societies, may be exchanged by a set of men called *merchants*, for an equivalent, proper for supplying every want, without any interruption to industry, or any check upon consumption.

It is a point as yet undecided by the learned, to what nation the invention and first use of commerce belonged;

belonged ; some attribute it to one people, some to another, for reasons that are too long to be discussed here. But it seems most probable that the inhabitants of Arabia were those that first made long voyages. It must be allowed, that no country was so happily seated for this purpose as that which they inhabited, being a peninsula washed on three sides by three famous seas, the Arabian, Indian, and Persian. It is also certain, that it was very early inhabited ; and the first notice we have of any considerable trade refers it to the Ishmaelites, who were settled in the lither part of Arabia. To them Joseph was sold by his brethren, when they were going down with their camels to Egypt with spicery, balm, and myrrh. It may seem strange to infer from hence, that commerce was already practised by this nation, since mention is here made of camels, or a caravan, which certainly implies an inland trade ; and it must be likewise allowed, that balm and myrrh were the commodities of their country. But whence had they the spicery ? Or how came Arabia to be so famous in ancient times for spices ? Or whence proceeded that mistake of many great authors of antiquity, that spices actually grew there ? Most certainly, because these people dealt in them ; and that they dealt in them the first of any nation that we know of, appears from this very instance. Strabo and many other good authors assure us, that in succeeding times they were very great traders ; they tell us particularly what ports they had ; what prodigious magazines they kept of the richest kinds of goods, what wonderful wealth they obtained ; in what prodigious magnificence they lived, and into what excesses they fell in respect to their expences for carving, building, and statues. All this shews that they were very great traders ; and it also shews, that they traded to the East Indies ; for from thence only they could have their spices, their rich gums, their sweet-scented woods, and their ivory, all which it is expressly said that they had in the greatest abundance. This therefore proves, that they had an extensive and flourishing commerce ; and that they had it earlier than any other nation, seems to me evident from their dealing at that time in spices. Besides, there is much less difficulty in supposing that they first discovered the route to the Indies, than if we ascribe that discovery to any other nation : for in the first place they lay nearest, and in the next they lay most conveniently ; to which we may add thirdly, that as the situation of their country naturally inclined them to navigation, so by the help of the monsoons they might make regular voyages to and from the Indies with great facility ; nor is it at all unlikely that this discovery might be at first owing to chance, and to some of their vessels being blown by a strong gale to the opposite coast, from whence they might take the courage to return, by observing the regularity of the winds at certain seasons. All these reasons taken together seem to favour this opinion, that commerce flourished first among them ; and as to its consequences in making them rich and happy, there is no dispute about them.

We find in the records of antiquity no nation celebrated more early for carrying all arts to perfection than the inhabitants of Egypt ; and it is certain also, that no art was there cultivated more early, with

more assiduity, or with greater success, than trade. It appears from the foregoing instance, that the richest commodities were carried thither by land ; and it is no less certain, that the most valuable manufactures were invented and brought to perfection there many ages before they were thought of in other countries ; for, as the learned Dr Warburton very justly observes, at the time that Joseph came into Egypt, the people were not only possessed of all the conveniences of life, but were remarkable also for their magnificence, their politeness, and even for their luxury ; which argues, that traffic had been of long standing amongst them. To say the truth, the great advantages derived from their country's lying along the Red Sea, and the many benefits that accrued to them from the Nile, which they very emphatically called *the river*, or *the river of Egypt*, and of which they knew how to make all the uses that can be imagined, gave them an opportunity of carrying their inland trade not only to a greater height than in any country at that time, but even higher than it has been carried any where, China only excepted ; and some people have thought it no trivial argument to prove the descent of the Chinese from the Egyptians, that they have exactly the same sort of genius, and with wonderful industry and care have drawn so many cuts and canals, that their country is almost in every part of it navigable. It was by such methods, by a wife and well-regulated government, and by promoting a spirit of industry amongst the people, that the ancient Egyptians became so numerous, so rich, so powerful ; and that their country, for large cities, magnificent structures, and perpetual abundance, became the glory and wonder of the old world.

The Phenicians, though they possessed only a narrow slip of the coast of Asia, and were surrounded by nations so powerful and so warlike that they were never able to extend themselves on that side, became famous, by erecting the first naval power that makes any figure in history, and for the raising of which they took the most prudent and effectual measures. In order to this, they not only availed themselves of all the creeks, harbours, and ports, which nature had bestowed very liberally on their narrow territory, but improved them in such a manner, that they were no less remarkable for their strength, than considerable for their conveniency ; and so attentive they were to whatever might contribute to the increase of their power, that they were not more admired for the vast advantages they derived from their commerce, than they were formidable by their fleets and armies. They were likewise celebrated by antiquity as the inventors of arithmetic and astronomy ; and in the last mentioned science they must have been very considerable proficient, since they had the courage to undertake long voyages at a time when no other nation (the Arabians and Egyptians excepted) durst venture farther than their own coasts. By these arts Tyre and Sidon became the most famous marts in the universe, and were resorted to by all their neighbours, and even by people at a considerable distance, as the great storehouses of the world. We learn from the Scriptures, how advantageous their friendship and alliance became to the two great kings of Israel, David and

and Solomon; and we see, by the application of the latter for architects and artists to Hiram king of Tyre, to what a prodigious height they had carried manufactures of every kind.

It is very certain that Solomon made use of their assistance in equipping his fleets at Elath and Eziongaber; and it is very probable that they put him upon acquiring those ports, and gave him the first hints of the amazing advantages that might be derived from the possession of them, and from the commerce he might from thence be able to carry on. These ports were most commodiously situated on the Arabian gulph; and from thence his vessels, manned chiefly by Phœnicians, sailed to Ophir and Tharhis, where-ever those places were. Some writers will needs have them to be Mexico and Peru, which is certainly a wild and extravagant supposition; others believe that we are to look for Ophir on the coast of Africa, and Tharhis in Spain; but the most probable opinion is, that they were both seated in the East Indies. By this adventurous navigation he brought into his country curiosities not only unseen, but unheard of before, and riches in such abundance, that, as the Scripture finely expresses it, *He made silver in Jerusalem as stones, and cedar-trees as sycamores that grew in the plains.* The metaphor is very bold and emphatical; but when we consider that it is recorded in this History, that the return of one voyage only to Ophir produced 450 talents of gold, which makes 51,328 pounds of our Troy weight, we cannot doubt of the immense profit that accrued from this commerce. It is also observable, that the queen of Sheba, or Saba, which lies in that part of Arabia before-mentioned, surprised at the reports that were spread of the magnificence of this prince, made a journey to his court on purpose to satisfy herself, whether fame had not exaggerated the fact; and from the presents she made him of 120 talents of gold, of spices in great abundance, and precious stones, we may discern the true reason of her curiosity, which proceeded from an opinion that no country could be so rich as her own. And there is another circumstance very remarkable, and which seems strongly to fortify what we have advanced in the beginning of this section; it is added, *neither were there any such spices as the queen of Sheba gave to king Solomon;* which seems to intimate, that the Arabians had penetrated farther into the Indies than even the fleets of this famous prince, and brought from thence other spices (perhaps nutmegs and cloves) than had ever been seen before. It was by his wisdom, and by his steady application to the arts of peace, all of which mutually support each other, as they are all driven on by the wheel of commerce, which supplies every want, and converts every superfluity into merchandise, that this monarch raised his subjects to a condition much superior to that of any of their neighbours, and rendered the land of Israel, while he governed it, the glory and wonder of the East. He made great acquisitions without making wars; and his successor, by making wars, lost those acquisitions. It was his policy to keep all his people employed; and, by employing them, he provided equally for the extension of their happiness, and his own power: but the following kings pursued other

VOL. III.

measures, and other consequences attended them. The trade of Judea sunk almost as suddenly as it rose, and in process of time they lost those ports on the Red Sea, upon which their Indian commerce depended.

The whole trade of the universe became then, as it were, the patrimony of the Phœnicians and the Egyptians. The latter monopolized that of the Indies, and, together with her corn and manufactures, brought such a prodigious balance of wealth continually into the country, as enabled the ancient monarchs of Egypt to compals all those memorable works that in spite of time and barbarous conquerors remain the monuments of their wisdom and power, and are like to remain so as long as the world subsists. The Phœnicians drew from Egypt a great part of those rich commodities and valuable manufactures which they exported into all the countries between their own and the Mediterranean sea; they drew likewise a vast resort to their own cities, even from countries at a great distance; and we need only look into the prophets Isaiah and Ezekiel in order to be convinced, that these governments, founded on trade, were infinitely more glorious and more stable than those that were erected by force. All this we find likewise confirmed by profane histories; and by comparing these, it is evident, that the industry of the inhabitants of this small country triumphed over all obstacles, procured the greatest plenty in a barren soil, and immense riches, where, without industry, there must have been the greatest indigence. It is true, that old Tyre was destroyed by Nebuchadnezzar, but not till she had flourished for ages; and even then she fell with dignity, and after a resistance that ruined the army of the Great Conqueror of Asia. Out of the ashes of this proud city the great spirit of its inhabitants produced a Phoenix, little, if at all, inferior in beauty to its parent. New Tyre was situated on an island; and though her bounds were very narrow, yet she became quickly the mistress of the sea, and held that supreme dominion till subdued by Alexander the Great, whom no power could resist. The struggle she made, however, though unsuccessful, was great, and very much to the honour of her inhabitants: it must be owned, that the Greek hero found it more difficult to master this single place, than to overcome the whole power of Persia.

The views of the Macedonian prince were beyond comparison more extensive than his conquests; and whoever considers Alexander's plan of power, and enters into it thoroughly, will think him more a politician than he was a conqueror. He framed in his own mind an idea of universal monarchy, which it was indeed impossible to accomplish; but the very notion of it does him far greater honour than all his victories. He thought of placing his capital in Arabia; and of disposing things in such a manner, as to have commanded the most remote parts of the Indies, at the same time that he maintained a connection with the most distant countries in Europe. He was for making use of force to acquire, but he very well knew, that commerce only could preserve, an empire, that was to have no other limits than those which nature had assigned the world. He desired to be master of all; but at the same time he was willing to be

a wife and gracious master, and to place his happiness in that of his people, or rather, in making all the nations of the earth but one people. A vast, an extravagant, an impracticable scheme it was, of which he lived not long enough to draw the out-lines; but the sample he left in his new city of Alexandria sufficiently shews how just and how correct his notions were, and how true a judgment he had formed of what might be effected by those methods upon which he depended. That city, which he might be said to design with his own hand, and which was built, as it were, under his eye, became in succeeding times all that he expected, the glory of Egypt, and the centre of commerce for several ages.

While Tyre was in the height of her glory, and had no rival in the empire of the sea, she founded her noble colony of Carthage on the coast of Africa. The situation of the city was every way admirable; whether considered in the light of a capital, of a strong fortress, or of a commodious port. It was equally distant from all the extremities of the Mediterranean sea, had a very fine country behind it, and was not in the neighbourhood of any power capable of restraining its commerce or its growth. It is almost inexpressible how soon its inhabitants became not only numerous and wealthy, but potent and formidable. By degrees they extended themselves on all sides, conquered the best part of Spain, and erected there a new Carthage; the islands of Sicily and Sardinia, or at least the best part of them, submitted likewise to their yoke. But their conquests, however, were inconsiderable in extent, when compared with their navigation. On one side they stretched as far westward as Britain; and the Scilly islands, which are now so inconsiderable, were to them an Indies, the route to which they used the utmost industry to conceal. On the other hand, they discovered a great part of the coast of Africa, the Canary islands; and some there are, who believe they first found the way to America. While they confined themselves to trade, and the arts which belonged thereto, their power was continually increasing; but when industry gave way to luxury, and a spirit of ambition banished their old maxims of frugality and labour, their acquisitions remained at a stand. The Romans began to grow jealous of their naval power, which it cost them two obnoxious wars of 40 years continuance to humble. When she was at length destroyed, her very ruins were majestic; for at the beginning of the third fatal Punic war, this city contained 700,000 inhabitants alone, and had 300 cities in Africa under her dominion. Such was the empire of Carthage, raised entirely by commerce; and to which, if she had been content to have applied herself with the same steadiness in her highest prosperity as in her early beginnings, there is no doubt she had preferred her freedom much longer than she did; for as thrift, and diligence, and good faith, are the pillars of a commercial state, so when these are once shaken, it is not only natural that she should decline, but unavoidable also.

The Ptolemies, who were the successors of Alexander in Egypt, entered deeply into that hero's scheme, and reaped the benefit of his wise establishment. Ptolemy Philadelphus, by encouraging trade, made his subjects immensely rich, and himself inexpressibly

powerful. We are told by an ancient author, that he had 120 galleys of war of an enormous size, and upwards of 4000 other vessels, small and great. This would appear incredible, if other wonders were not related of him, which seem to explain and confirm these. He raised a new city on the coast of the Red Sea; he was at an immense expence in opening harbours, constructing quays, in raising inns at proper distances on the road, and in cutting a canal from sea to sea. A prince who comprehended the importance of commerce to a degree that induced him to dare such expences as these, might have what treasures, what armies, what fleets he pleased. In his time, Alexandria appeared in pomp and splendour. She owed her birth to Alexander; but it was Ptolemy, who caught a double portion of his master's spirit, which raised her to that magnificence that ages could not deface. We may guess at what she was in her glory, by what we are told was the produce of her customs, which fell little short of two millions of our money annually; and yet we cannot suppose that Ptolemy, who understood trade so well, would cramp it by high duties, or extravagant impositions. When the revenue of the prince from a single port was so great, what must have been the riches of his subjects!

But what shews us Alexandria in the highest point of light, is the credit she maintained after Egypt sunk from an empire into a province. The Romans themselves were struck with the majesty of her appearance; and though till then they had little regarded traffic, yet they were not long before they comprehended the advantages of such a port, and such a mart as Alexandria; they confirmed her privileges, they protected her inhabitants, they took every measure possible to preserve her commerce, and this with so good an effect, that she actually preserved it longer than Rome herself could preserve her power. She followed, indeed, the fortune of the empire, and became at last dependent upon Constantinople, when its founder removed thither the capital of the empire; and his successor found means to transfer also a part of the trade of Alexandria to the same place. Yet this city continued still to hold up her head, and tho' she sunk under the barbarous power of the Arabs, yet they grew polished by degrees; by degrees she recovered somewhat of her ancient pre-eminence; and though she never rose to any thing like her former lustre, yet she remained the centre of what little trade there was in the world; which is more than can be said of almost any place that has fallen under the Mohammedan power.

When the Roman empire was over-run by barbarians, and arts and sciences sunk with that power which had cultivated and protected them, commerce also visibly declined; or, to speak with greater propriety, was overwhelmed and lost. When that irruption of various nations had driven the Roman policy out of the greatest part of Europe, some straggling people, either forced by necessity, or led by inclination, took shelter in a few straggling islands that lay near the coast of Italy, and which would never have been thought worth inhabiting in a time of peace. This was in the 6th century; and at their first fixing there they had certainly nothing more in view than living in a tolerable

able state of freedom, and acquiring a subsistence as well as they could. These islands being divided from each other by narrow channels, and those channels so incumbered by shallows that it was impossible for strangers to navigate them, these refugees found themselves tolerably safe; and, uniting amongst themselves for the sake of improving their condition, and augmenting their security, they became in the 8th century a well-settled government, and assumed the form of a republic.

Simple and mean as this relation may appear, yet it is a plain and true account of the rise, progress, and establishment of the famous and potent republic of Venice. Her beginnings were indeed weak and slow; but when the foundation was once well laid, her growth was quick, and the increase of her power amazing. She extended her commerce on all sides; and taking advantage of the barbarous maxims of the Mohammedan monarchies, she drew to herself the profits of the Indian trade, and might, in some sense, be said to make Egypt a province, and the Saracens her subjects. By this means her traffic swelled beyond conception; she became the common mart of all nations; her naval power arrived at a prodigious height; and, making use of every favourable conjuncture, she stretched her conquest not only over the adjacent Terra Firma of Italy, but though the islands of the Archipelago, so as to be at once mistress of the sea, of many fair and fruitful countries, and of part of the great city of Constantinople itself. But ambition, and the desire of lordship it over her neighbours, brought upon her those evils which first produced a decay of trade, and then a declension of power. General histories indeed ascribe this to the league of Cambray, when all the great powers in Europe combined against this republic; and in truth, from that period, the sinking of her power is truly dated; but the Venetian writers very justly observe, that though this effect followed the league, yet there was another more latent, but at the same time a more effectual cause, which was, the falling off of their commerce; and they have ever since been more indebted to their wisdom than their power; to the prudent concealing of their own weakness, and taking advantage of the errors of their enemies, than to any other cause, for their keeping up that part which they still bear, and which had been lost long ago by any other nation but themselves.

At the same time that Venice rose, as it were, out of the sea, another republic was erected on the coast of Italy. There could not well be a worse situation than the narrow, marshy, unprofitable, and unwholesome islands in the Adriatic, except the rocky, barren, and inhospitable shores of Liguria, and yet as commerce raised Venice the Rich on the one, so she erected Genoa the Proud on the other. In spite of ambitious and warlike neighbours, in spite of a confined and unproducing country, and, which were still greater impediments, in spite of perpetual factions and successive revolutions, the trade of Genoa made her rich and great. Her merchants traded to all countries, and threw by carrying the commodities of the one to the other. Her fleets became formidable; and, besides the adjacent island of Corsica, she made larger

and important conquests. She fixed a colony at Caffa, and was for some time in possession of the coasts on both sides of the Black Sea. That emulation which is natural to neighbouring nations, and that jealousy which rises from the pursuit of the same mistress, commerce, begat continual wars between these rival republics; which, after many obstinate and bloody battles, were at last terminated in favour of Venice, by that famous victory of Chiozza gained by her doge Andrew Contarini, from which time Genoa never pretended to be mistress of the sea. These quarrels were fatal to both; but what proved more immediately destructive to the Genoese, was their avarice, which induced them to abandon the fair profits of trade for the sake of that vile method of acquiring wealth by usury.

But we must now look to another part of the world. In the middle age of the German empire, that is, about the middle of the 13th century, there was formed a confederacy of many maritime cities, or at least of cities not far from the sea. This confederacy solely regarded commerce, which they endeavoured to promote and extend, by interesting therein a great number of persons, and endeavouring to profit by their different views and different lights. Though the cities of Germany held the principal rank in the Teutonic Hanse, they did not however forbear associating many other cities, as well in France as in England and in the low countries; the whole, however, without hurting the authority, without prejudice to the rights, of the sovereign on whom they depended. This confederacy had its laws, its ordinances, and its judgments, which were observed with the same respect as the maritime code of the Rhodians, who, passing for the ablest seamen in all antiquity, their constitutions were observed by the Greeks and Romans. The Teutonic Hanse grew in a short time to so high a rank in power and authority by the immense riches it acquired, that princes themselves rendered it a sincere homage from principles of esteem and admiration. Those of the north principally had frequent occasion for their credit, and borrowed of them considerable sums. The grand masters of the Teutonic order, who were at that time sovereigns of Livonia, declared themselves conservators of the rights and privileges of the Hanse: all succeeded, not only to, but beyond their wishes; and Germany, charmed with their progress, looked on them with the same eyes as a curious gardener does on certain rare plants, though not of his own raising and culture. The kings of France and England granted also various privileges to the Teutonic confederacy; they exempted their vessels in case of shipwreck from all demands whatsoever from the admiralty, or from private persons; they forbade any disturbance to their navigation at all times; and even when France was at war with the emperor, or the princes of the north. In fine, during the course of those unhappy wars which were titled *Croisades*, the Hanse was signally consulted, and gave always puissant succours in money and in ships to the Christians oppressed by infidels. It is astonishing, that cities at so great a distance from each other, subject to different kings, sometimes in open war, but always jealous of their rights, should be able to confederate and live to-

gether in so strict a union. But when this union had rendered them very rich and powerful, it cannot seem at all strange, that on the one hand they grew arrogant and overbearing, took upon them not only to treat with sovereigns on the foot of equality, but even to make war with them, and more than once with success. It will, on the other hand, appear still less strange, that such behaviour as this awakened various princes to a more particular view of the dangers that such a league might produce, and the advantages that would naturally flow to their respective states, by recovering their trade thus made over, at least in some part to others, entirely to themselves; and these, in few words, were the causes of the gradual declension of the Hanſatic alliance: which, however, is not totally dissolved at this day; the cities of Lubeck, Hamburgh, and Bremen, maintaining sufficient marks of that splendor and dignity with which this confederacy was once adorned.

We must now turn our eyes to Portugal and Spain, where in the space of about 50 years there happened a train of events which gradually led on to such discoveries as changed the whole face of affairs in the commercial world, and gave to the knowledge of later ages what for some thousand years had been kept secret from all mankind, we mean a perfect and distinct notion of that terraqueous globe which they inhabit. The kingdom of Portugal was small, but well cultivated, very populous, and blessed with a variety of good ports; all which, however, had flood them in little stead, if they had not had a succession of wise princes, who, instead of involving themselves in war with their neighbours to gratify their ambition, endeavoured to extend the happiness and wealth of their subjects, and by so doing their own power, in the softer and more successful method of protecting arts and sciences, encouraging industry, and favouring trade. This, with the convenient situation of their country, in the beginning of the 15th century, prompted some lively spirits to attempt discoveries; and these, countenanced by an heroic young prince, pushed on their endeavours with such success, that step by step the coast of Africa was surveyed as far as the Cape of Good Hope, to which they gave that name. The point they had in view was a new route to the East Indies, which Vasquez de Gama happily discovered; and in a short space of time Portugal, from one of the least considerable, grew to be one of the richest powers in Europe, gained prodigious dominions in Asia and Africa, and raised a naval power superior to any thing that had been seen for many ages before.

But while this was doing, Christopher Columbus, a Genoese of great capacity, though of almost unknown original, who had been bred to the sea from his youth, and who had carefully studied what others made a trade, formed in his mind the amazing project of counteracting experience, and sailing to the Indies by a west course. He offered this project to the Portuguese, by whom it was considered and rejected as a chimera. He proposed it afterwards to other states, but with no better fortune; and at last owed the discovery of the New World to the high spirit of a heroine, the famous Isabella queen of Castile, who almost at her own expence, and with very little coun-

tenance from her husband, who yet was siled *Ferdinand and the Wife*, furnished the adventurous Columbus with that poor Squadron, with which at once, in spite of all the difficulties that the envy of his officers, and the obstinacy of his mutinous crew, threw in his way, perfected his design, and laid open a new Indies, though in reality he aimed at the discovery of the old. Neither was this noble effort of his matchless understanding defeated; for after his decease, Ferdinand Magellan, a Portuguese, proposed to the emperor Charles V. the discovery of a passage to the spice Islands by the South Seas, which was what Columbus aimed at; and though Magellan lived not to return, yet in one voyage the discovery was perfected. It is inconceivable almost how many and how great benefits accrued to Europe from these discoveries; of which, however, it is certain, that the Portuguese made a very indifferent, and the Spaniards much worse, use; the former making slaves of, and the latter rooting out, the natives. This, as it was a most ungrateful return to divine Providence for so high a blessing; so it might have been easily foreseen it would prove, as experience has shewn it did prove, highly prejudicial to their own interests, by depopulating very fine countries, which have been thereby turned into deserts; and though on their first discovery infinite treasures were returned from them, which were coined in the mints of Spain; yet, by an obstinate pursuit of this false policy, the Spanish Islands in the West Indies are now brought so low as to be scarce worth keeping. The consequences that naturally followed on the discovery of a passage by the Cape of Good Hope, and of a fourth part of the globe in the western hemisphere, were, as it has been already hinted, the cause of an entire change in the state of Europe, and produced, not only in Portugal and Spain, but in most other nations, a desire of visiting these remote parts, of establishing colonies, of setting manufactures on foot, of exporting and importing commodities; and of raising, settling, and protecting new manufactures. By this means, as the reader cannot but perceive not only particular nations brought about signal advantages to themselves, but Europe in general received a lasting and invaluable benefit: for its potentates made themselves formidable, and even terrible in those distant parts of the earth, and where their fame had hardly reached before. It is however true, that this has not been carried on as high as it might have been; for though there was room enough for every nation to have had its share, and though it might be demonstrated that the good of the whole would have contributed sufficiently to the profit of every state, the subjects of which had engaged in this traffic; yet, instead of prosecuting so natural and so equitable a measure, they have taken a quite contrary course; and by decrying, attacking, and destroying each other, have very much lessened that prodigious reverence which the Asiatics, Africans, and Americans, at first had for the inhabitants of Europe.

The naval power of the Portuguese received an incurable wound by falling under the power of the Spaniards: and though human policy would have suggested, that this alone must have raised the latter to the monopoly of commerce, and the universal dom-

nion

nion of the sea; yet the very pursuit of a design so visibly detrimental to the interest of mankind, proved very quickly their ruin also. For the Spaniards, from the natural haughtiness of their temper, misled by the boundless ambition of their princes, and endeavouring to become the lords of Europe, forced other nations in their own defence to make a much quicker progress in navigation than otherways they could have done. For the English and Dutch, who till this time seemed blind to the advantages of their situation, had their eyes opened by the injuries they received; and by degrees the passion of revenge inspired them with designs that possibly public spirit had never excited. In short, the pains taken by Spain to keep all the riches that flowed from these discoveries to herself, and the dangerous, detestable, and destructive purposes to which she applied the immense wealth that flowed in upon her from them, produced effects directly opposite to those which she proposed, and made her enemies rich, great, powerful, and happy, in proportion as her commerce dwindled away, and as her naval power sunk and crumbled to pieces merely by an improper display, an ill-managed exertion, and a wrong application of it.

It was from hence that the inhabitants of the Seven Provinces, whom her oppression had made poor, and her severities driven mad, became first free, then potent, and by degrees rich. Their distresses taught them the necessity of establishing a moderate and equal government; the mildness of that government, and the blessings which it procured to its subjects, raised their number, and elevated their hopes. The consequences became quickly visible, and in a short space of time amazing both to friends and enemies; every fishing village improved into a trading town; their little towns grew up into large and magnificent cities; their inland boroughs were filled with manufactures; and in less than half a century the distressed States of Holland became high and mighty; nay, in spite of the danger and expences which attended a war, made all that time against a superior force, these people, surrounded with enemies, loaded with taxes, exposed to personal service, and to a thousand other disadvantages, grew up to such a strength as not only made the Spaniards despair of reducing them any more under their dominion, but inclined them to wish, and at last forced them to seek, their friendship.

This, at least as far as either ancient or modern histories inform us, was the quickest and strongest of all the productions of commerce that the world has ever seen. For it is out of dispute, that the republic of the United Provinces owes her freedom, her power, and her wealth, to industry and trade intirely. The greatest part of the country is nothing less than fertile; and what is so, produces not enough to suffice the tenth part of its inhabitants for the tenth part of the year: the climate is rather tolerable than wholesome; and its havens are rather advantageous from the difficulty of entering them, than from their commodiousness in any other respect. Native commodities they have few or none; timber and maritime stores are entirely wanting; their country cannot boast so much as of a coal-mine; and yet these provinces, upon which nature has bestowed so little, in

consequence of an extensive trade, are enriched with all things. Their storehouses are full of corn, even when the harvest in corn-countries fails; there is no commodity, how bulky soever, or however scarce and hard to come at, which may not be had from their magazines. The shipping of Holland is prodigious; and to see the quantities of naval stores with which their yards and ports abound, astonishes those who are unacquainted with the vigour of that cause which produces this abundance. But above all, the populousness of this country is the greatest miracle. That men should resort to a Canaan, and desire to live in a land flowing with milk and honey, is nothing strange; but that they should make it their choice to force nature to raise palaces, lay out gardens, dig canals, plant woods, and ransack all the quarters of the earth for fruit and flowers, to produce an artificial paradise in a dead plain, or upon an ingrateful heath in the midst of fogs and standing lakes, would, in so critical an age as this, pass for a fable, if the country did not lie so near us, as to put the truth of it out of question.

§ 2. *British History.*

WE may easily conceive, that foreign commerce by the natives of this island must have been a work of time; for men think first of necessities, then of conveniences, and last of superfluities. Those who came originally from the continent might have better notions of things; but as it must be presumed that either fear or indigence drove them hither, so it is easy to apprehend that succeeding generations must for some time sink much below their ancestors, in their notions of the commodities of life; and, deriving their manners from their circumstances, become quite another sort of people. But those on the opposite continent, knowing that this island was inhabited, and having the use, though in ever so imperfect a degree, of vessels, and of foreign traffic, came over hither, and bartered their goods for the raw commodities of the Britons, till by degrees perhaps they taught the latter to make some improvement in those slight leather and wicker boats, which they used for passing their own rivers, and creeping along their coasts, till at last they ventured themselves over to Gaul, and entered upon some kind of correspondence with their neighbours. All this is so deducible from the laws of nature, that we might have divined thus much by the light of reason, if we had not the commentaries of Cæsar to guide us, and to strengthen by the authority of history the facts that might have been found out by the force of rational conjecture.

Things were precisely in this situation when the Romans invaded Britain; and there is no doubt that our ancestors falling under the power of that empire, and under its power at a time when with respect to arts and sciences it was in a most flourishing condition, was a great advantage to them; and though from their love of civil liberty, which, when under the direction of reason, is the most natural and laudable of all passions, they made a long and vigorous, and in some sense a noble and glorious resistance; yet by degrees they caught the manners and customs of their conquerors, and grew content to be happy rather than free. With learning and politeness the Romans introduced

roduced foreign commerce; and according to the nature of their policy, as they made high roads through the island, established colonies in proper places, and fixed standing camps, which were a kind of fortresses, where they thought proper; so they were no less careful with regard to marts or emporiums for the convenience of traders, and of which what they found is uncertain: but that they left many, is without question; and amongst the rest London, which is not more famous for her present extensive trade, than venerable for her unrecorded antiquity.

When the Romans unwillingly left Britain, and the Britons as unwillingly made way for the Saxons, a new deluge of barbarity overflowed this island: almost all the improvements of our civilized conquerors were defaced; and upon the establishment as it were of a new people, things were all to begin again. This necessarily took up a great deal of time; and before they were in any tolerable posture, the Saxons found themselves distressed by fresh swarms of barbarians. Yet there still remains some evidences of their having been acquainted with, inclined to, and, if their circumstances would have permitted, most certainly would have entered upon and carried foreign commerce to a great height. We have authentic testimonies, that Alfred the Great formed projects of vast discoveries to the North, as he actually sent persons of great prudence and abilities into the East; and the curiosities which they brought home were for many ages preserved in the treasury of the church of Salisbury.

As for the Danes, they were not long our masters: but as they became so by a maritime force, and as their countrymen had established themselves not only on the opposite shore of France, but in other parts of Europe; so it is reasonable to believe that they held some correspondence with them from hence; and that, if their dominion had lasted longer, this might have been better regulated, and productive of many advantages. But they had soon to do with their brethren in another way: for the Normans, men of the same race, but better established in another country, dispossessed them here; and partly under colour of right, partly by force, erected that monarchy, which, not without various alterations and changes, subsists even to our times, and to the subsistence of which, with the help of those changes and alterations, we owe that happy constitution under which we live; that universal improvement which adorn the face of our country; that domestic trade which nourishes so numerous a people, by plentifully rewarding their industry; and that extensive commerce which is at once the source of our wealth and the support of our liberty.

It cannot be expected, that in a work like this, we should attempt to trace the progress of trade through every reign, shew how it was encouraged and protected, or discountenanced and checked; what occasions were luckily seized, or what opportunities unfortunately lost. It may be sufficient for us, after what has been already said, to observe, that the opinion commonly entertained, of our having little or no trade before the reign of queen Elizabeth, is very far from being well founded.

In fact, the reign of that princess was great and

glorious, in whatever light we consider it; but it was most so in this, that, under Providence, it became great and glorious by the wisdom and prudence of the queen and her ministers. The English nation never was in so dilapidate a condition as at her accession. The crown was in debt, the treasury empty, the nation involved in a foreign war directly against her own interests, her coffers naked; in a word, without credit abroad, and without concord at home, no settled religion, the great men split into factions, and the common people distracted and dejected. Sad circumstances these! and yet from hence arose the grandeur of that reign, and the establishment of our commerce. The queen found herself obliged to act with great caution, to derive assistance from every quarter, to employ it faithfully, and to promote to the utmost of her power the welfare of her subjects, whom nothing but the public-spirit of her government could enable to grow rich enough to support the necessary expences of the crown. It was this that gave a popular turn to her councils. She encouraged her subjects to arm against the Spaniards, that they might be accustomed to the sea, and acquire that knowledge in navigation, with which, till then, they had been unacquainted. She passed many laws for the public good, erected several companies, and saw that those companies pursued the ends for which they were erected; in short, she did every thing that could be expected, during the whole course of her reign, to excite and encourage industry at home, and to enable us to make a proper figure abroad. In a word, she furnished us with stock and credit, put us upon improving our commodities and manufactures, brought the art of ship-building amongst us, filled our ports with able seamen, shewed a just respect to English merchants, reduced Ireland so as to render it beneficial to Britain, and approved our sending colonies into America; and thus the seeds of British wealth were sown in her time, though the harvest was reaped in the days of her successors. See the articles COALERY, COLONY, FISHERIES, MANUFACTURES, SHIPPING, and TRADE.

CHAP. II. PRINCIPLES of COMMERCE.

§ i. *Origin of Trade.*

THE most simple of all trade, is that which is carried on by bartering the necessary articles of subsistence. If we suppose the earth free to the first possessor, this person who cultivates it will first draw from it his food, and the surplus will be the object of barter: he will give this in exchange to any one who will supply his other wants. This naturally supposes both a surplus quantity of food produced by labour, and also free hands; for he who makes a trade of agriculture cannot supply himself with all other necessities, as well as food; and he who makes a trade of supplying the farmers with such necessities, in exchange for his surplus of food, cannot be employed in producing that food. The more the necessities of man increase, the more free hands are required to supply them; and the more free hands are required, the more surplus food must be produced by additional labour, to supply their demand.

This

This is the least complex kind of trade, and may be carried on to a greater or less extent, in different countries, according to the different degrees of the wants to be supplied. In a country where there is no money, nor any thing equivalent to it, the wants of mankind will be confined to few objects; to wit, the removing the inconveniencies of hunger, thirst, cold, heat, danger, and the like. A free man, who, by his industry, can procure all the comforts of a simple life, will enjoy his rest, and work no more: and, in general, all increase of work will cease, so soon as the demand for the purposes mentioned comes to be satisfied. There is a plain reason for this. When the free hands have procured, by their labour, wherewithal to supply their wants, their ambition is satisfied: so soon as the husbandmen have produced the necessary surplus for relieving theirs, they work no more. Here then is a natural stop put to industry, consequently to bartering.

The next thing to be examined is, how bartering grows into trade, properly so called and understood, according to the definition given of it above; how trade comes to be extended among men; how manufactures, more ornamental than useful, come to be established; and how men come to submit to labour, in order to acquire what is not absolutely necessary for them.

This, in a free society, is chiefly owing to the introduction of money, and a taste for superfluities in those who possess it.

In ancient times, money was not wanting; but the taste for superfluities not being in proportion to it, the specie was locked up. This was the case in Europe four hundred years ago. A new taste for superfluity has drawn, perhaps, more money into circulation, from our own treasures, than from the mines of the new world. The poor opinion we entertain of the riches of our fore-fathers, is founded upon the modern way of estimating wealth, by the quantity of coin in circulation, from which we conclude, that the greatest part of the specie now in our hands must have come from America.

It is more, therefore, through the taste of superfluity, than in consequence of the quantity of coin, that trade comes to be established; and it is only in consequence of trade that we see industry carry things in our days to so high a pitch of refinement and delicacy. Let us illustrate this, by comparing together the different operations of barter, sale, and commerce.

When reciprocal wants are supplied by barter, there is not the smallest occasion for money: this is the most simple of all combinations.

When wants are multiplied, bartering becomes more difficult, upon this money is introduced. This is the common price of all things: it is a proper equivalent in the hands of those who want, perfectly calculated to supply the occasions of those who, by industry, can relieve them. This operation of buying and selling is a little more complex than the former; but still we have here no idea of trade, because we have not introduced the merchant, by whose industry it is carried on.

Let this third person be brought into play, and the

whole operation becomes clear. What before we called *wants*, is here represented by the consumer; what we called *industry*, by the manufacturer; what we called *money*, by the merchant. The merchant here represents the money, by substituting credit in its place; and as the money was invented to facilitate barter, to the merchant, with his credit, is a new refinement upon the use of money. This renders it still more effectual in performing the operations of buying and selling. This operation is trade: it relieves both parties of the whole trouble of transportation, and adjusting wants to wants, or wants to money; the merchant represents by turns both the consumer, the manufacturer, and the money. To the consumer he appears as the whole body of manufacturers; to the manufacturers as the whole body of consumers; and to the one and the other class his credit supplies the use of money. This is sufficient at present for an illustration. We now return to the simple operations of money in the hands of the two contracting parties, the buyer and the seller, in order to show how men come to submit to labour in order to acquire superfluities.

So soon as money is introduced into a country, it becomes an universal object of want to all the inhabitants.

The consequence is, that the free hands of the state, who before slopt working, because all their wants were provided for, having this new object of ambition before their eyes, endeavour, by refinements upon their labour, to remove the smaller inconveniencies which result from a simplicity of manners. People, who formerly knew but one sort of clothing for all seasons, willingly part with a little money to procure for themselves different sorts of apparel properly adapted to summer and winter, which the ingenuity of manufacturers, and their desire of getting money, may have suggested to their invention.

Indeed these refinements seem more generally owing to the industry and invention of the manufacturers, (who by their ingenuity daily contrive means of softening or relieving inconveniencies, which mankind seldom perceive to be such, till the way of removing them is contrived), than to the taste of luxury in the rich, who, to indulge their ease, engage the poor to become industrious.

Let any man make an experiment of this nature upon himself, by entering into the first shop. He will no where so quickly discover his wants as there. Every thing he sees appears either necessary, or at least highly convenient; and he begins to wonder how he could have been so long without that which the ingenuity of the workman alone had invented, in order that from the novelty it might excite his desire; for perhaps when it is bought, he will never once think of it more, nor ever apply it to the use for which it at first appeared so necessary.

Here then is a reason why mankind labour though not in want. They become desirous of possessing the very instruments of luxury, which their avarice or ambition prompted them to invent for the use of others.

What has been said represents trade in its infancy, or rather the materials with which that great fabrick is built.

We have formed an idea of the wants of mankind multiplied even to luxury, and abundantly supplied by the employment of all the free hands set apart for that purpose. But if we suppose the workman himself disposing of his work, and purchasing with it food from the farmer, cloaths from the clothier; and, in general, seeking for the supply of every want from the hands of the person directly employed for the purpose of relieving it; this will not convey an idea of trade according to our definition.

Trade and commerce are an abbreviation of this long process; a scheme invented and set on foot by merchants, from a principle of gain, supported and extended among men, from a principle of general utility to every individual, rich or poor, to every society, great or small.

Instead of a pin-maker exchanging his pins with 50 different persons, for whose labour he has occasion, he sells all to the merchant for money or for credit; and, as occasion offers, he purchases all his wants, either directly from those who supply them, or from other merchants who deal with manufacturers in the same way his merchant dealt with him.

Another advantage of trade is, that industrious people in one part of the country, may supply customers in another, though distant. They may establish themselves in the most commodious places for their respective business, and help one another reciprocally, without making the distant parts of the country suffer for want of their labour. They are likewise exposed to no avocation from their work, by seeking for customers.

Trade produces many excellent advantages; it marks out to the manufacturers when their branch is under or over-stocked with hands. If it is understocked, they will find more demand than they can answer; if it is overstocked, the sale will be slow.

Intelligent men, in every profession, will easily discover when these appearances are accidental, and when they proceed from the real principles of trade.

Posts, and correspondence by letters, are a consequence of trade; by the means of which merchants are regularly informed of every augmentation or diminution of industry in every branch, in every part of the country. From this knowledge they regulate the prices they offer; and as they are many, they serve as a check upon one another, from the principles of competition.

From the current prices, the manufacturers are as well informed, as if they kept the correspondence themselves: the statesman feels perfectly where hands are wanting, and young people destined to industry, obey, in a manner, the call of the public, and fall naturally in to supply the demand.

Two great assistances to merchants, especially in the infancy of trade, are public markets for collecting the work of small dealers, and large undertakings in the manufacturing way by private hands. By these means the merchants come at the knowledge of the quantity of work in the market, as on the other hand the manufacturers learn, by the sale of the goods, the extent of the demand for them. These two things being justly known, the price of goods is easily fixed.

Public sales serve to correct the small inconveni-

encies which proceed from the operations of trade. A set of manufacturers got all together into one town, and entirely taken up with their industry, are thereby as well informed of the rate of the market as if every one of them carried thither his work, and upon the arrival of the merchant, who readily takes it off their hands, he has not the least advantage over them from his knowledge of the state of demand. This man both buys and sells in what is called *wholesale*; and from him retailers purchase, who distribute the goods to every consumer throughout the country. These last buy from wholesale merchants in every branch, that proportion of every kind of merchandize which is suitable to the demand of their borough, city, or province.

Thus all inconveniences are prevented, at some additional cost to the consumer, who must naturally reimburse the whole expence. The distance of the manufacturer, the obscurity of his dwelling, the caprice in selling his work, are quite removed; the retailer has all in his shop, and the public buys at a current price.

§ ii. *How the prices of Goods are determined by Trade.*

In the price of goods, two things must be considered as really existing, and quite different from one another; to wit, the real value of the commodity, and the profit upon alienation.

I. The first thing to be known of any manufacture, when it comes to be sold, is, how much of it a person can perform in a day, a week, a month, according to the nature of the work, which may require more or less time to bring it to perfection. In making such estimates, regard is to be had only to what, upon an average, a workman of the country in general may perform, without supposing him the best or the worst in his profession, or having any peculiar advantage or disadvantage as to the place where he works.

Hence the reason why some people thrive by their industry, and others not; why some manufactures flourish in one place, and not in another.

II. The second thing to be known, is the value of the workman's subsistence, and necessary expence, both for supplying his personal wants, and providing the instruments belonging to his profession, which must be taken upon an average as above; except when the nature of the work requires the presence of the workman in the place of consumption: for although some trades, and almost every manufacture, may be carried on in places at a distance, and therefore may fall under one general regulation as to prices; yet others there are, which, by their nature, require the presence of the workman in the place of consumption; and in that case the prices must be regulated by circumstances relative to every particular place.

III. The third and last thing to be known, is the value of the materials, that is, the first matter employed by the workman; and if the object of his industry be the manufacture of another, the same process of inquiry must be gone through with regard to the first, as with regard to the second: and thus the most complex manufactures may be at last reduced to the greatest simplicity.

These three articles being known, the price of manufacture

facture is determined. It cannot be lower than the amount of all the three, that is, than the real value; whatever it is higher, is the manufacturer's profit. This will ever be in proportion to demand, and therefore will fluctuate according to circumstances.

Hence appears the necessity of a great demand, in order to promote flourishing manufactures.

By the extensive dealings of merchants, and their constant application to the study of the balance of work and demand, all the above circumstances are known to them, and are made known to the industrious, who regulate their living and expence according to their certain profit.

Employ a workman in a country where there is little trade or industry, he proportions his price always to the urgency of your want, or your capacity to pay; but seldom to his own labour. Employ another in a country of trade, he will not impose upon you, unless perhaps you be a stranger, which supposes your being ignorant of the value; but employ the same workman in a work not usual in the country, consequently not demanded, consequently not regulated as to the value, he will proportion his price as in the first supposition.

We may therefore conclude, from what has been said, that in a country where trade has been established, manufactures must flourish, from the ready sale, the regulated price of work, and the certain profit resulting from industry. Let us next inquire into the consequences of such a situation.

§ iii. *How foreign Trade opens to an industrious People and the Consequences of it to the Merchants who set it on foot.*

THE first consequence of the situation described in the preceding section is, that wants are easily supplied, for the adequate value of the thing wanted.

The next consequence is, the opening of foreign trade, under its two denominations of passive and active. Strangers and people of distant countries, finding the difficulty of having their wants supplied at home, and the ease of having them supplied from this country, immediately have recourse to it. This is passive trade. The active is when merchants, who have executed this plan at home with success, begin to transport the labour of their countrymen into other regions, which either produce, or are capable of producing such articles of consumption, proper to be manufactured, as are most demanded at home; and consequently will meet with the readiest sale, and fetch the largest profits.

Hence then is the opening of foreign trade, under its two denominations of active and passive.

What then are the consequences of this new commerce to our merchants, who have left their homes in quest of gain abroad?

The first is, that, arriving in any new country, they find themselves in the same situation, with regard to the inhabitants, as the workman in the country of no trade, with regard to those who employ him; that is, they proportion the price of their goods to the eagerness of acquiring, or the capacity of paying, in the inhabitants, but never to their real value.

The first profits then, upon this trade, must be very considerable; and the demand from such a country

will be *high or low, great or small*, according to the spirit, not the real wants of the people: for these in all countries must first be supplied by the inhabitants themselves, before they cease to labour.

If the people of this not-trading country be abundantly furnished with commodities useful to the traders, they will easily part with them, at first, for the instruments of luxury and ease; but the great profit of the traders will insensibly increase the demand for the productions of their new correspondents; this will have the effect of producing a competition between themselves, and thereby of throwing the demand on their side. This is perpetually a disadvantage in traffic: the most unpolished nations in the world quickly perceive the effects of it; and are taught to profit by the discovery, in spite of the address of those who are the most expert in commerce.

The traders will therefore be very fond of falling upon every method and contrivance to inspire this people with a taste of refinement and delicacy. Abundance of fine presents, consisting of every instrument of luxury and superfluity, the best adapted to the genius of the people, will be given to the prince and leading men among them. Workmen will even be employed at home, to study the taste of the strangers, and to captivate their desires by every possible means. The more eager they are of presents, the more lavish the traders will be in bestowing and diversifying them. It is an animal put up to fatten, the more he eats the sooner he is fit for slaughter. When their taste for superfluity is fully formed, when the relish for their former simplicity is sophisticated, poisoned, and obliterated, then they are surely in the fetters of the traders, and the deeper they go, the less possibility there is of their getting out. The presents then will die away, having served their purpose; and if afterwards they are found to be continued, it will probably be to support the competition against other nations, who will incline to share of the profits.

If, on the contrary, this not-trading nation does not abound with commodities useful to the traders, these will make little account of trading with them, whatever their turn may be; but, if we suppose this country inhabited by a laborious people, who, having taken a taste for refinement from the traders, apply themselves to agriculture, in order to produce articles of subsistence, they will solicit the merchants to give them part of their manufactures in exchange for those; and this trade will undoubtedly have the effect of multiplying numbers in the trading nation. But if food cannot be furnished, nor any other branch of production found out to support the correspondence, the taste for refinement will soon die away, and trade will stop in this quarter.

Had it not been for the furs in those countries adjacent to Hudson's Bay, and in Canada, the Europeans never would have thought of supplying instruments of luxury to those nations; and if the inhabitants of those regions had not taken a taste for the instruments of luxury, furnished to them by the Europeans, they never would have become so indefatigable nor so dextrous hunters. At the same time we are not to suppose, that ever these Americans would have come to Europe in quest of our manufactures. It is, therefore, owing

to our merchants, that these nations are become in any degree fond of refinement ; and this taste, in all probability, will not soon exceed the proportion of the productions of their country. From these beginnings of foreign trade it is easy to trace its increase.

One step towards this, is the establishing correspondences in foreign countries ; and these are more or less necessary in proportion as the country where they are established is more or less polished or acquainted with trade. They supply the want of posts, and point out to the merchants what proportion the productions of the country bear to the demand of the inhabitants for manufactures. This communicates an idea of commerce to the not-trading nation, and they insensibly begin to fix a determined value upon their own productions, which perhaps bore no determined value at all before.

Let us trace a little the progress of this refinement in the savages, in order to show how it has the effect of throwing the demand upon the traders, and of creating a competition among them, for the productions of the new country.

Experience shews, that, in a new discovered country, merchants constantly find some article or other of its productions, which turns out to a great account in commerce ; and we see that the longer such a trade subsists, and the more the inhabitants take a taste for European manufactures, the more their own productions rise in their value, and the less profit is made by trading with them, even in cases where the trade is carried on by companies ; which is a very wise institution for one reason, that it cuts off a competition between our merchants.

This is the best means of keeping prices low in favour of the nation ; however it may work a contrary effect with respect to individuals who must buy from these monopolies.

When companies are not established, and when trade is open, our merchants, by their eagerness to profit by the new trade, betray the secrets of it, they enter into competition for the purchase of the foreign produce, and this raises prices, and favours the commerce of the most ignorant savages.

§ iv. *Consequences of the Introduction of a passive foreign Trade among a People who live in simplicity and Idleness.*

We now suppose the arrival of traders, all in one interest, with instruments of luxury and refinement, at a port in a country of great simplicity of manners, abundantly provided by nature with great advantages for commerce, and peopled by a nation capable of adopting a taste for superfluities.

The first thing the merchants do is, to expose their goods, and point out the advantages of many things, either agreeable or useful to mankind in general, such as wines, spirits, instruments of agriculture, arms, and ammunition for hunting, nets for fishing, manufactures for cloathing, and the like. The advantages of these are presently perceived, and such commodities are eagerly sought after.

The natives on their side, produce what they most esteem, generally something superfluous or ornamental. The traders after examining all circumstances,

determine the object of their demand, giving the least quantity possible in return for this superfluity, in order to impress the inhabitants with a high notion of the value of their own commodities ; but as this parsimony may do more hurt than good to their interest, they are very generous in making presents, from the principles mentioned above.

When the exchange is completed, and the traders depart, regret is commonly mutual ; the one and the other are sorry that the superfluities of the country fall short. A return is promised by the traders, and assurances are given by the natives of a better provision another time.

What are the first consequences of this revolution ?

It is evident, that, in order to supply an equivalent for this new want, more hands must be set to work than formerly. And it is evident also, that this augmentation of industry will not essentially increase numbers : Why ? Because the produce of the industry is, in this case, intended to be exported. But, if we can find out any additional consumption at home, even implied by this new trade, it will have the effect of augmenting numbers. An example will make this plain.

Let us suppose the superfluity of this country to be the skins of wild beasts, not proper for food ; the manufacture sought for, brandy. The brandy is sold for furs. He who has furs, or he who can spare time to hunt for them, will drink brandy in proportion : but there is no reason to conclude from this simple operation, that one man more in the country must necessarily be fed, or that any augmentation of agriculture must of consequence ensue from this new traffic.

But let us throw in a circumstance which may apply an additional consumption at home, and then examine the consequences.

A poor creature who has no equivalent to offer for food, who is miserable, and ready to perish for want of subsistence, goes a hunting, and kills a wolf ; he comes to a farmer with the skin, and says. You are well fed, but you have no brandy ; if you will give me a loaf, I will give you this skin, which the strangers are so fond of, and they will give you brandy. But, says the farmer, I have no more bread than what is sufficient for my own family. As for that, replies the other, I will come and dig in your ground, and you and I will settle our account as to the small-quantity I desire of you. The bargain is made ; the poor fellow gets his loaf, and lives at least ; perhaps he marries, and the farmer gets a dram. But had it not been for this dram, that is, this new want, which was purchased by the industry of this poor fellow, by what argument could he have induced the farmer to part with a loaf ?

Here the sentiment of charity is excluded. This alone is a principle of multiplication ; but as true it is, on the other hand, that could the poor fellow have got bread by begging, he would not probably have gone a hunting.

Here then it appears, that the very dawning of trade, in the most unpolished countries, implies a multiplication. This is enough to point out the first step, and to connect the subject of our present inquiries with what has been already discussed in relation to other circumstances.

So soon as all the furs are disposed of, and a taste for superfluity is introduced, both the traders and the natives will be equally interested in the advancement of industry in this country. Many new objects of profit for the first will be discovered, which the proper employment of the inhabitants, in reaping the natural advantages of their soil and climate, will make effectual. The traders will therefore endeavour to set on foot many branches of industry among the savages, and the allurements of brandy, arms, and clothing, will animate these in the pursuit of them.

When once this revolution is brought about; when those who formerly lived in simplicity become industrious; and manners put on a new face.

That is to say, we now find two trading nations instead of one, with this difference, however, that as hitherto we have supposed the merchants all in one interest, the compound demand, that is, the competition of the buyers, has been, and must still continue on the side of the natives. This is a great prejudice to their interest; but as it is not supposed sufficient to check their industry, nor to restrain their consumption of the manufactures, let us here examine a little more particularly the consequences of the principle of demand in such a situation; for although we allow, that it can never change sides, yet it may admit of different modifications, and produce different effects, as we shall presently perceive.

The merchants we suppose all in one interest, consequently there can be no competition among them; consequently no check can be put upon their raising their prices, as long as the prices they demand are complied with. So soon as they are raised to the full extent of the abilities of the natives, or of their inclination to buy, the merchants have the choice of three things, which are all perfectly in their option; and the preference to be given to the one or the other, depends entirely upon themselves, and upon the circumstances we are going to point out.

First, they may support their *high* demand; that is, not lower their price; which will preserve a high estimation of the manufactures in the opinion of the inhabitants, and render the profits upon their trade the greatest possible. This part they may possibly take, if they perceive the natives doubling their diligence, in order to become able, in time, to purchase considerable cargoes at a high value; from which supposition is implied a strong disposition in the people to become luxurious, since nothing but want of ability prevents them from complying with the highest demand: but still another circumstance must concur, to engage the merchants not to lower their price. The great proportion of the goods they seek for in return, must be found in the hands of a few. This will be the case if slavery be established; for then there must be many poor and few rich: and they are commonly the rich consumers who proportion the price they offer, rather to their desires, than to the value of the thing.

The second thing which may be done is, to open the door to a *great* demand; that is, to lower their prices. This will sink the value of the manufactures in the opinion of the inhabitants, and render profits less in proportion, although indeed, upon the voyage, the profits may be greater.

This part they will take, if they perceive the inhabitants do not incline to consume great quantities of the merchandize at a high value, either for want of abilities or inclination; and also, if the profits upon the trade depend upon a large consumption, as is the case in merchandize of a low value, and suited chiefly to the occasions of the lower sort. Such motives of expediency will be sufficient to make them neglect a high demand, and prefer a great one; and the more, when there is a likelihood that the consumption of low priced goods in the beginning may beget a taste for others of a higher value, and thus extend in general the taste of superfluity.

A third part to be taken, is the least politic, and perhaps the most familiar. It is to profit by the competition between the buyers, and encourage the rising of demand as long as possible; when this comes to a stop, to make a kind of auction, by first bringing down the prices to the level of the highest bidders, and so to descend by degrees, in proportion as demand sinks. Thus we may say with propriety, that demand commonly becomes great, in proportion as prices sink. By this operation, the traders will profit as much as possible, and sell off as much of their goods as the profits will permit.

But this plan, in a new discovered country, is not politic, as it both discovers a covetousness and a want of faith in the merchants, and also throws open the secrets of their trade to those who ought to be kept ignorant of them.

Let us next suppose, that the large profits of our merchants shall be discovered by others, who arrive at the same ports in a separate interest, and who enter into no combination which might prevent the natural effects of competition.

Let the state of demand among the natives be supposed the same as formerly, both as to height and greatness, in consequence of the operation of the different principles, which might have induced our merchants to follow one or other of the plans we have been describing; we must however still suppose, that they have been careful to preserve considerable profits upon every branch.

If we suppose the inhabitants to have increased in numbers, wealth, and taste for superfluity, since the last voyage, demand will be found rather on the rising hand. Upon the arrival of the merchants in competition with the former, both will offer to sale: but if both stand to the same prices, it is very natural to suppose, that the former dealers will obtain a preference; as, *ceteris paribus*, it is always an advantage to know and to be known. The last comers, therefore, have no other way left to counter-balance this advantage, but to lower their prices.

This is a new phenomenon: here the fall of prices is not voluntary as formerly; nor consented to from expediency; nor owing to a failure of demand, but to the influence of a new principle of commerce, to wit, a double competition, which we shall now examine.

§ v. Of double Competition.

WHEN competition is much stronger on one side of the contract than on the other, it is called *simple*.

This is the species of competition which is implied in the term *high demand*, or when it is said that *demand raises prices*.

Double competition is, when, in a certain degree, it takes place on both sides of the contract at once, or vibrates alternately from one to the other. This is what restrains prices to the adequate value of merchandize.

The great difficulty is to distinguish clearly between the principles of *demand*, and those of *competition*: here then follows the principal differences between the two, relatively to the effects they produce severally in the mercantile contract of buying and selling, which we here express shortly by the word *contract*.

Simple demand is what brings the quantity of a commodity to market. Many demand, who do not buy; many offer, who do not sell. This demand is called *great* or *small*; it is said to increase, to augment, to swell; and is expressed by these and other synonymous terms, which mark an augmentation or diminution of quantity. In this species, two people never demand the same thing, but a part of the same thing, or things quite alike.

Compound demand is the principle which raises prices, and can never make them sink; because in this case more than one demands the very same thing. It is solely applicable to the buyers, in relation to the price they offer. This demand is called *high* or *low*, and is said to rise, to fall, to mount, to sink, and is expressed by these and other synonymous terms.

Simple competition, when between buyers, is the same as *compound* or *high demand*; but differs from it in so far, as this may equally take place among sellers, which compound demand cannot; and then it works a contrary effect: it makes prices sink, and is synonymous with *low demand*: it is this competition which overturns the balance of work and demand.

Double competition is what is understood to take place in almost every operation of trade; it is this which prevents their excessive rise of prices; it is this which prevents their excessive fall. While double competition prevails, the balance is perfect, trade and industry flourish.

The capital distinction, therefore, between the terms *demand* and *competition* is, that *demand* is constantly relative to the buyers; and when money is not the price, as in barter, then it is relative to that side upon which the greatest *competition* is found.

We therefore say, with regard to *prices*, demand is *high* or *low*. With regard to the *quantity of merchandize*, demand is *great* or *small*. With regard to *competition*, it is always called *great* or *small*, *strong* or *weak*.

Competition is, with equal propriety, applicable to both parties in the contract. A *competition* among buyers is a proper expression; a *competition* among sellers, who have the merchandize, is fully as easily understood, though it be not quite so striking, for reasons which an example will make plain.

You come to a fair, where you find a great variety of every kind of merchandize, in the possession of different merchants. These, by offering their goods to sale, constitute a tacit competition; every one of them wishes to sell in preference to another, and at the same time with the best advantage to himself.

The buyer begins, by cheapening at every shop. The first price asked marks the covetousness of the seller; the first price offered, the avarice of the buyer. From this operation competition begins to work its effects on both sides, and so becomes double. The principles which influence this operation are now to be deduced.

It is impossible to suppose the same degree of eagerness, either to buy or to sell, among several merchants; because the degree of eagerness is exactly in proportion to their view of profit; and as these must necessarily be influenced and regulated by different circumstances, that buyer, who has the best prospect of selling again with profit, obliges him, whose prospect is not so good, to content himself with less; and that seller, who has bought to the best advantage, obliges him, who has paid dearer for the merchandize, to moderate his desire of gain.

It is from these principles, that competition among buyers and sellers must take place. This is what confines the fluctuation of prices within limits which are compatible with the reasonable profits of both buyers and sellers; for we must constantly suppose the whole operation of buying and selling to be performed by merchants; the buyer cannot be supposed to give so high a price as that which he expects to receive, when he distributes to the consumers, nor can the seller be supposed to accept of a lower than that which he paid to the manufacturer. This competition is properly called *double*, because of the difficulty to determine upon which side it stands; the same merchant may have it in his favour upon certain articles, and against him upon others; it is continually in vibration, and the arrival of every post may less or more pull down the heavy scale.

In every transaction between merchants, the profit resulting from the sale must be exactly distinguished from the value of the merchandize. The first may vary, the last never can. It is this profit alone which can be influenced by competition; and it is for that reason we find such uniformity every where in the prices of goods of the same quality.

The competition between sellers does not appear so striking as that between buyers; because he who offers to sale, appears only passive in the first operation; whereas the buyers present themselves one after another; they make a demand when the merchandize is refused to one at a certain price, a second either offers more, or does not offer all: but so soon as another seller finds his account in accepting the price the first had refused, then the first enters into competition, providing his profits will admit his lowering the first price, and thus competition takes place among the sellers, until the profits upon their trade prevent prices from falling lower.

In all markets this competition is varying, though insensibly, on many occasions; but in others the vibrations are very perceptible. Sometimes it is found strongest on the side of the buyers; and in proportion as this grows, the competition between the sellers diminishes. When the competition between the former has raised prices to a certain standard, it comes to a stop; then the competition changes sides, and takes place among the sellers, eager to profit of the highest price. This makes prices fall, and according as they fall,

fall, the competition among the buyers diminishes. They still wait for the lowest period. At last it comes; and then perhaps some new circumstance, by giving the balance a kick, disappoints their hopes. If therefore it ever happens, that there is but one interest upon one side of the contract, as in the example in the former section, where we supposed the sellers united, you perceive, that the rise of the price, occasioned by the competition of the buyers, and even its coming to a stop, could not possibly have the effect of producing any competition on the other side; and therefore, if prices come afterwards to sink, the fall must have proceeded from the prudential considerations of adapting the price to the faculties of those who, from the height of it, had withdrawn their demand.

From these principles of competition, the forestalling of markets is made a crime, because it diminishes the competition which ought to take place between different people, who have the same merchandize to offer to sale. The forestaller buys up all, with an intention to sell with more profit, as he has by that means taken other competitors out of the way, and appears with a single interest on one side of the contract, in the face of many competitors on the other. This person is punished by the state, because he has prevented the price of the merchandize from becoming justly proportioned to the real value; he has robbed the public, and enriched himself; and in the punishment he makes restitution. Here occur two questions to be resolved, for the sake of illustration.

Can competition among buyers possibly take place, when the provision made is more than sufficient to supply the quantity demanded? On the other hand, can competition take place among the sellers, when the quantity demanded exceeds the total provision made for it?

We think it may in both cases; because in the one and the other, there is a competition implied on one side of the contract, and the very nature of this competition implies a possibility of its coming on the other, provided separate interests be found upon both sides. But to be more particular:

1. Experience shews, that however justly the proportion between the demand and the supply may be determined in fact, it is still next to impossible to discover it exactly, and therefore the buyers can only regulate the prices they offer, by what they may reasonably expect to sell for again. The sellers, on the other hand, can only regulate the prices they expect, by what the merchandize has cost them when brought to market. We have already shewn, how, under such circumstances, the several interests of individuals affect each other, and make the balance vibrate.

2. The proportion between the supply and the demand is seldom other than *relative* among merchants, who are supposed to buy and sell, not from necessity, but from a view to profit. What we mean by *relative* is, that their demand is *great* or *small*, according to prices; there may be a great demand for grain at 35 s. *per* quarter, and no demand at all for it at 40 s.; that is, among merchants.

It is essential to attend to the smallest circumstance in matters of this kind. The circumstance we mean, is the difference we find in the effect of competition,

when it takes place purely among merchants on both sides of the contract, and when it happens, that either the consumers mingle themselves with the merchant-buyers or the manufacturers, that is, the furnishers, mingle themselves with the merchant-sellers. This combination we shall illustrate by the solution of another question, and then conclude with a few reflections upon the whole.

Can there be no case formed, where the competition upon one side may subsist, without a possibility of its taking place on the other, although there should be separate interests upon both?

The case is hardly supposable among merchants, who buy and sell with a view to profit; but it is absolutely supposable, and that is all, when the direct consumers are the buyers; when the circumstances of one of the parties is perfectly known; and when the competition is so strong upon one side, as to prevent a possibility of its becoming double, before the whole provision is sold off, or the demand satisfied. Let us have recourse to examples.

Grain arriving in a small quantity, at a port where the inhabitants are starving, produces so great a competition among the consumers, who are the buyers, that their necessity becomes evident; all the grain is generally bought up before prices can rise so high as to come to a stop; because nothing but want of money, that is, an impossibility of complying with the prices demanded by the merchants, can restrain them: but if you suppose, even here, that prices come naturally to a stop; or that, after some time, they fall lower, from prudential considerations; then there is a possibility of a competition taking place among the sellers, from the principles above deduced. If, on the contrary, the stop is not natural, but occasioned by the interposition of the magistrate, from humanity, or the like, there will be no competition, because then the principles of commerce are suspended; the sellers are restrained on one side, and they restrain the buyers on the other. Or rather indeed, it is the magistrate, or compassion, who in a manner fixes the price, and performs the office of both buyer and seller.

A better example still may be found, in a competition among sellers; where it may be so strong as to render a commodity in a manner of no value at all, as in the case of an uncommon and unexpected draught of fish, in a place of small consumption, when no preparations have been made for salting them. There can be then no competition among the buyers; because the market cannot last, and they find themselves entirely masters, to give what price they please, being sure the sellers must accept of it, or lose their merchandize. In the first example, humanity commonly stops the activity of the principle of competition; in the other, it is stopped by a certain degree of fair dealing, which forbids the accepting of a merchandize for nothing.

In proportion therefore as the rising of prices can stop demand, or the sinking of prices can increase it, in the same proportion will competition prevent either the rise or the fall from being carried beyond a certain length: and if such a case can be put, where the rising of prices cannot stop demand, nor the lowering of prices augment it, in such cases double competition has

no effect; because these circumstances unite the most separate interests of buyers and sellers in the mercantile contract; and when upon one side there is no separate interest, there can then be no competition.

From what has been said, we may form a judgment of the various degrees of competition. A book not worth a shilling, a fish of a few pounds weight, are often sold for considerable sums. The buyers here are not merchants. When an ambassador leaves a court in a hurry, things are sold for less than the half of their value: he is no merchant, and his situation is known. When, at a public market, there are found consumers, who make their provision; or manufacturers, who dispose of their goods for present subsistence; the merchants, who are respectively upon the opposite side of the contract to these, profit of their competition; and those who are respectively upon the same side with them, stand by with patience until they have finished their business. Then matters come to be carried on between merchant and merchant, and then profits may rise and fall, in the proportion of quantity to demand; that is to say, if the provision is less than the demand, the competition among the demanders, or the rise of the price, will be in the compound proportion of the falling short of the commodity, and of the prospect of selling again with profit. It is this combination which regulates the competition, and keeps it within bounds. It can affect but the profits upon the transaction: the intrinsic value of the commodity stands immovable: nothing is ever sold below the real value; nothing is ever bought for more than it may probably bring. We mean in general. Whereas, so soon as consumers and needy manufacturers mingle in the operation, all proportion is lost. The competition between them is too strong for the merchants; the balance vibrates by jerks. In such markets merchants seldom appear: the principal objects there, are the fruits and productions of the earth, and articles of the first necessity for life, not manufactures strictly so called. A poor fellow often sells to purchase bread to eat; not to pay what he did eat while he was employed in the work he disposes of. The consumer often measures the value of what he is about to purchase, by the weight of his purse, and his desire to consume.

§ vi. Of what is called *Expense, Profit, and Loss*.

The term *expense*, when simply expressed, without any particular relation, is always understood to be relative to money. This kind is distinguished under the three heads of *private, public, and national*.

1. *Private expense* is, what a private person, or private society, lays out, either to provide articles of consumption, or something more permanent, which may be conducive to their ease, convenience, or advantage. Thus we say, a *large domestic expense*, relative to one who spends a great income. We say, a merchant has been at *great expense* for magazines, for living, for clerks, &c. but never that he has been at any in buying goods. In the same way a manufacturer may expend for building, machines, horses, and carriages, but never for the matter he manufactures. When a thing is bought, in order to be sold again, the sum employ-

ed is called money *advanced*; when it is bought not to be sold, it may be said to be *expended*.

2. *Public expense* is, the employment of that money, which has been contributed by individuals, for the current service of the state. The contribution, or gathering it together, represents the effects of many articles of *private expense*; the laying it out when collected, is *public expense*.

3. *National expense*, is what is expended out of the country; this is what diminishes national wealth. The principal distinction to be here attended to, is between public expense, or the laying out of public money, and national expense, which is the alienating the nation's wealth in favour of strangers. Thus the greatest public expense imaginable, may be no national expense; because the money may remain at home. On the other hand, the smallest public, or even private expense, may be a national expense; because the money may go abroad.

Profit and loss, is divided into *positive, relative, and compound*. *Positive profit* implies no loss to any body; it results from an augmentation of labour, industry, or ingenuity, and has the effect of swelling or augmenting the public good.

Positive loss, implies no profit to any body; it is what results from the cessation of the former, or of the effects resulting from it, and may be said to diminish the public good.

Relative profit, is what implies a loss to some body; it marks a vibration of the balance of wealth between parties, but implies no-addition to the general stock.

Relative loss, is what, on the contrary, implies a profit to some body; it also marks a vibration of the balance, but takes nothing from the general stock.

The *compound* is easily understood; it is that species of profit and loss which is partly relative, and partly positive.

§ vii. The general consequences resulting to a trading Nation, upon the opening of an active foreign Commerce.

A nation which remains passive in her commerce, is at the mercy of those who are active, and must be greatly favoured, indeed, by natural advantages, or by a constant flux of gold and silver from her mines, to be able to support a correspondence, not entirely hurtful to the augmentation of her wealth.

When we look upon the wide field which here opens to our view, we are perplexed with too great a variety of objects. In one part, we see a decent and comely beginning of industry; wealth flowing gently in, to recompense ingenuity; numbers both augmenting, and every one becoming daily more useful to another; agriculture proportionally extending itself; no violent revolutions; no exorbitant profits; no insolence among the rich; no excessive misery among the poor; multitudes employed in producing; great economy upon consumption; and all the instruments of luxury, daily produced by the hands of the diligent, going out of the country for the service of strangers; not remaining at home for the gratification of sensuality. At last the augmentations come insensibly to a stop. Then these rivers of wealth, which were in brisk circulation through the whole world, and which returned

returned to this trading nation as blood returns to the heart, only to be thrown out again by new pulsations, begin to be obstructed in their course; and flowing abroad more slowly than before, come to form stagnations at home. Thieft, impatient of restraint, soon burst out into domestic circulation. Upon this cities swell in magnificence of buildings; the face of the country is adorned with palaces, and becomes covered with groves; luxury shines triumphant in every part; inequality becomes more striking to the eye; and want and misery appear more deformed, from the contrast: even fortune grows more whimsical in her inconsistency; the beggar of the other day, now rides in his coach; and he who was born in a bed of state, is seen to die in a goal, or in an almshouse. Such are the effects of great domestic circulation.

The statesman looks about with amazement; he who was wont to consider himself as the first man in the society in every respect, perceives himself, perhaps, eclipsed by the lustre of private wealth, which avoids his grasp when he attempts to seize it. This makes his government more complex and more difficult to be carried on; he must now avail himself of art and address, as well as of power and force. By the help of cajoling and intrigues, he gets a little into debt; this lays a foundation for public credit, which, growing by degrees, and in its progress assuming many new forms, becomes, from the most tender beginnings, a most formidable monster, striking terror into those who cherished it in its infancy. Upon this, as upon a triumphant war-horse, the statesman gets astride; he then appears formidable a-new; his head turns giddy; he is choaked with the dust he has raised; and at the moment he is ready to fall, to his utter astonishment and surprise, he finds a strong monied interest, of his own creating, which, instead of swallowing him up as he apprehended, flies to his support. Through this he gets the better of all opposition, he establishes taxes, multiplies them, mortgages his fund of subsistence; either becomes a bankrupt, and rises again from his ashes; or if he be less audacious, he stands trembling and tottering for a while on the brink of the political precipice. From one or the other of these perilous situations, he begins to discover an endless path, which, after a multitude of windings, still returns into itself, and continues an equal course through this vast labyrinth.

It is now full time to leave off rhapsody, and return to reasoning and cool enquiry, concerning the more immediate and more general effects and revolutions produced by the opening of a foreign trade in a nation of industry.

The first and most sensible alteration will be an increase of demand for manufacturers, because by supplying the wants of strangers, the number of consumers will now be considerably augmented. What again will follow upon this, must depend upon circumstances.

If this revolution in the state of demand should prove too violent, the consequence of it will be to raise demand; if it should prove gradual, it will increase it. This distinction is well understood, and the consequence appears just: for, if the supply do not increase in proportion to the demand, a competition

will ensue among the demanders; which is the common effect of such sudden revolutions. If, on the other hand, a gentle increase of demand should be accompanied with a proportional supply, the whole industrious society will grow in vigour, and in wholesome stature, without being sensible of any great advantage or inconvenience; the change of their circumstances will even be imperceptible.

The immediate effects of the violent revolution will, in this example, be flattering to some, and disagreeable to others. Wealth will be found daily to augment, from the rising of prices, in many branches of industry. This will encourage the industrious classes, and the idle consumers at home will complain. We have already dwelt abundantly long upon the effect resulting from this to the lower classes of the people, in providing them with a certain means of subsistence. Let us now examine in what respect even the higher classes will be made likewise to feel the good effects of this general change, although at first they may suffer a temporary inconvenience from it.

Farmers, as has been observed, will have a greater difficulty in finding servants, who, instead of labouring the ground, will chuse to turn themselves to manufactures. This we have considered in the light of purging the lands of superfluous mouths; but every consequence in this great chain of politics draws other consequences after it, and as they follow one another, things put on different faces, which affect classes differently. The purging of the land is but one of the first; here follows another.

The desertion of the lands employed in a trifling agriculture will at first, no doubt, embarrass the farmers; but in a little time every thing becomes balanced in a trading nation, because here every industrious man must advance in prosperity, in spite of all general combinations of circumstances.

In the case before us, the relative profits upon farming must soon become greater than formerly, because of this additional expence which must affect the whole class of farmers; consequently, this additional expence, instead of turning out to be a loss to either landlord or farmer, will, after some little time, turn out to the advantage of both: because the produce of the ground, being indispensably necessary to every body, must in every article increase in its value. Thus in a short time accounts will be nearly balanced on all hands; that is to say, the same proportion of wealth will, *ceteris paribus*, continue the same among the industrious. We say among the industrious; for those who are either idle, or even negligent, will be great losers.

A proprietor of land, inattentive to the causes of his farmer's additional expence, may very imprudently suffer his rents to fall, instead of assisting him on a proper occasion, in order to make them afterwards rise the higher.

Those who live upon a determined income in money, and who are nowise employed in traffic, nor in any scheme of industry, will, by the augmentation of prices, be found in worse circumstances than before.

In a trading nation every man must turn his talents

to account, or he will undoubtedly be left behind in this universal emulation, in which the most industrious, the most ingenious, and the most frugal will constantly carry off the prize.

This consideration ought to be a spur to every body. The richest men in a trading nation have no security against poverty; we mean proportional poverty; for though they diminish nothing of their income, yet, by not increasing it in proportion to others, they lose their rank in wealth, and from the first class in which they stood they will slide insensibly down to a lower.

There is one consequence of an additional beneficial trade, which raises demand and increases wealth; but if we suppose no proportional augmentation of supply, it will prove at best but an airy dream which lasts for a moment, and when the gilded scene is passed away, numberless are the inconveniences which are seen to follow.

We shall now point out the natural consequences of this augmentation of wealth drawn from foreign nations, when the statesman remains inattentive to increase the supply both of food and manufactures, in proportion to the augmentation of mouths, and of the demand for the produce of industry.

In such a situation profits will daily swell, and every scheme for reducing them within the bounds of moderation, will be looked upon as a hurtful and unpopular measure: be it so; but let us examine the consequences.

We have said, that the rise of demand for manufactures naturally increases the value of work: now we must add, that under such circumstances, the augmentation of riches, in a country, either not capable of improvement as to the soil, or where precautions have not been taken for facilitating a multiplication of inhabitants, by the importation of subsistence, will be productive of the most calamitous consequences.

On one side, this wealth will effectually diminish the mass of the food before produced; and on the other, will increase the number of useless consumers. The first of these circumstances will raise the demand for food; and the second will diminish the number of useful free hands, and consequently raise the price of manufactures: here are shortly the outlines of this progress.

The more rich and luxurious a people are, the more delicate they become in their manner of living; if they fed on bread formerly, they will now feed on meat; if they fed on meat, they will now feed on fowl. The fane ground which feeds a hundred with bread, and a proportional quantity of animal food, will not maintain an equal number of delicate livers. Food must then become more scarce; demand for it rises; the rich are always the strongest in the market; they consume the food, and the poor are forced to starve. Here the wide door to modern distress opens; to wit, a hurtful competition for subsistence. Farther, when a people become rich, they think less of economy; a number of useless servants are hired, to become an additional dead weight on consumption; and when their starving countrymen cannot supply the extravagance of the rich so cheaply as other nations,

they either import instruments of foreign luxury, or seek to enjoy them out of their own country, and thereby make restitution of their gains.

Is it not therefore evident, that if, before things come to this pass, additional subsistence be not provided by one method or other, the number of inhabitants must diminish; although riches may daily increase by a balance of additional matter, supposed to be brought into the country in consequence of the hitherto beneficial foreign trade? This is not all. We say farther, that the beneficial trade will last for a time only. For the infallible consequence of the rise of prices at home will be, that those nations which at first consumed your manufactures, perceiving the gradual increase of their price, will begin to work for themselves; or finding out your rivals who can supply them cheaper, will open their doors to them. These again, perceiving the great advantages gained by your traders, will begin to supply the market; and since every thing must be cheaper in countries where we do not suppose the concurrence of all the circumstances mentioned above, these nations will supplant you, and be enriched in their turn.

Here comes a new revolution. Trade is come to a stop: what then becomes of all the hands which were formerly employed in supplying the foreign demands?

Were revolutions so sudden as we are obliged to represent them, all would go to wreck; in proportion as they happen by quicker or slower degrees, the inconveniences are greater or smaller.

Prices, we have said, are made to rise by competition. If the competition of the strangers was what raised them, the distress upon the manufacturers will be in proportion to the suddenness of their deserting the market. If the competition was divided between the strangers and the home-consumers, the inconveniences which ensue will be less; because the desertion of the strangers will be in some measure made up by an increase of home-consumption which will follow upon the fall of prices. And if, in the third case, the natives have been so imprudent, as not only to support a competition with the strangers, and thereby disgust them from coming any more to market, but even to continue the competition between themselves, the whole loss sustained by the revolution will be national. Wealth will cease to augment; but the inconveniences, in place of being felt by the manufacturers, will only affect the state; those will continue in affluence, extolling the generosity of their countrymen, and despising the poverty of the strangers who had enriched them.

Domestic luxury will here prove an expedient for preserving from ruin the industrious part of a people, who in subsisting themselves had enriched their country. No change will follow in their condition; they will go on with a painful assiduity to labour, and if the consequences of it become now hurtful to one part of the state, they must at least be allowed to be essentially necessary for the support of the other.

But that luxury is no necessary concomitant of foreign trade, in a nation where the true principles of it are understood, will appear very plain, from a contrast we are now going to point out, in the example

of a modern state, renowned for its commerce and frugality. The country is Holland.

A set of industrious and frugal people were assembled in a country by nature subject to many inconveniences, the moving of which necessarily employed abundance of hands. Their situation upon the continent, the power of their former masters, and the ambition of their neighbours, obliged them to keep great bodies of troops. These two articles added to the numbers of the community, without either enriching the state by their labour exported, or producing food for themselves or countrymen.

The scheme of a commonwealth was calculated to draw together the industrious; but it has been still more useful in subsisting them: the republican form of government being there greatly subdivided, vests authority sufficient in every part of it, to make suitable provision for their own subsistence; and the tie which unites them, regards only matters of public concern. Had the whole been governed by one sovereign, or by one council, this important matter never could have been effectuated.

It would be impossible for the most able minister that ever lived, to provide nourishment for a country so extended as France, or even as England, supposing these as fully peopled as Holland is: even although it should be admitted that a sufficient quantity of food might be found in other countries for their subsistence. The enterprise would be too great, abuses would multiply; the consequence would be, that the inhabitants would die for want. But in Holland the case is different, every little town takes care of its own inhabitants; and this care being the object of application and profit to so many persons, is accomplished with success.

When once it is laid down as a maxim in a country, that food must of necessity be got from abroad in order to feed the inhabitants at home, the corn-trade becomes considerable, and at the same time certain, regular, and permanent. This was the case in Holland: as the inhabitants were industrious, the necessary consequence has been, a very extraordinary multiplication; and at the same time such an abundance of grain, that, instead of being in want themselves, they often supply their neighbours. There are many examples of England's being supplied with grain from thence, and which is still more extraordinary, from the re-exportation of the very produce of its own fruitful soil.

It is therefore evident, that the only way to support industry, is to provide a supply of subsistence,

constantly proportional to the demand that may be made for it. This is a precaution indispensably necessary for preventing hurtful competition. This is the particular care of the Dutch: so long as it can be effectual, their state can fear no decline; but whenever they come to be distressed in the markets, upon which they depend for subsistence, they will sink into ruin. It is by mere dint of frugality, cheap and parsimonious living, that the navigation of this industrious people is supported. Constant employment, and an accumulation of almost imperceptible gains, fills their coffers with wealth, in spite of the large outgoings to which their own proper nourishment yearly forces them. The large profits upon industry in other countries, which are no proof of generosity, but a fatal effect of a scanty subsistence, is far from dazzling their eyes. They seldom are found in the list of competitors at any foreign port; if they have their cargo to dispose of, they wait with pleasure in their own vessels, consuming their own provisions, and at last accept of what others have left. It may be said, that many other circumstances concur in favour of the Dutch, besides the article of subsistence. Without disputing this matter, it may be observed, that if a computation be made of the hands employed in providing subsistence, and of those who are severally taken up in supplying every other want, their numbers will be found nearly to balance one another in the most luxurious countries. From this we may conclude, that the article of food, among the lower classes, must bear a very high proportion to all the other articles of their consumption; and therefore a diminution upon the price of subsistence, must be of infinite consequence to manufacturers, who are obliged to buy it. From this consideration, let us judge of the consequence of such augmentations upon the price of grain as are familiar to us; 30 or 40 *per cent.* seems nothing. Now this augmentation operates upon two-thirds, at least, of the whole expence of a labouring man: let any one who lives in tolerable affluence make the application of this to himself, and examine how he would manage his affairs if, by accidents of rains or winds, his expences were to rise 30 *per cent.* without a possibility of restraining them; for this is unfortunately the case with all the lower classes. From whence it may be concluded, that the keeping food cheap, and still more the preserving it at all times at an equal standard, is the fountain of the wealth of Holland; and that any hurtful competition in this article must beget a disorder which will affect the whole of the manufacturers of a state.

C O M

C O M

COMMERCE, a handsome town of France in the duchy of Bar, with the title of a principality, and a magnificent castle. It is seated on the river Meuse, in E. Long. 5. 24. N. Lat. 48. 20.

COMMUNION, an office in the liturgy of the church of England, appointed to be read on Ash-Wednesday, or the first day of Lent. It is substituted in the room of that *godly discipline in the primitive church*, by which, (as the introduction to the office expresses it), “such persons, as stood convicted

of notorious sins, were put to open penance, and punished in this world, that their souls might be saved in the day of the Lord; and that others, admonished by their example, might be the more afraid to offend.” This discipline, in after ages, degenerated, in the church of Rome, into a formal confession of sins upon Ash-Wednesday, and the empty ceremony of sprinkling ashes upon the heads of the people. Our reformers wisely rejected this ceremony, as mere shadow and show; and substituted this office in its room, which

Comminatory Commission. is *A denunciation of God's anger and judgment against sinners*; that the people, being apprized of God's wrath and indignation against sin, may not, through want of discipline in the church, be encouraged to follow and pursue them; but rather be moved to supply that discipline to themselves, and so to avoid being judged and condemned at the tribunal of God.

COMMUNATORY, an appellation given to whatever threatens punishment, or some penalty. Thus, in France, when an exile is enjoined not to return under pain of death, it is deemed a *communatory* penalty; since if he do return, it is not strictly executed; but a second injunction is laid on him, which is more than comminatory, and, from the day of the date thereof, imports death without remedy.

COMMINGES, a province of France, 45 miles in length, and 15 in breadth; bounded on the north by Galcony, on the south by Catalonia, on the east by Coufferrans, and on the west by Bigorra. Its principal trade consists in cattle, mules and corn. St Bertrand is the capital town.

COMMUNUTION, denotes the breaking, or rather grinding, a body to very small particles.

COMMIRE (John), a celebrated Latin poet, born at Amboise in 1625, entered into the society of the Jesuits, and taught polite literature and divinity. He died at Paris, in 1702. We have a volume of his Latin poems, and a collection of his posthumous works. His odes and fables are more particularly admired.

COMMISSARY, in the ecclesiastical law, an officer of the bishop, who exercises spiritual jurisdiction in places of a diocese so far from the Episcopal see, that the chancellor cannot call the people to the bishop's principal consistory court, without giving them too much inconvenience.

COMMISSARY-Court, in Scots law, a court originally constituted by the bishops for executing in their name an usurped jurisdiction; and was anciently called the *bishop's-court*, *curia Christianitatis*, or *consistorial court*. This court was modelled by queen Mary at the Reformation, and continues till this day. See *LAW*, Part III. N° clix. 22—26.

COMMISSARY, in a military sense, is of three sorts.

COMMISSARY-General of the Muskets, an officer appointed to muster the army, as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the musket-rolls, and to keep an exact state of the strength of the army.

COMMISSARY-General of the Stores, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

COMMISSARY-General of Provisions, an officer who has the charge of furnishing the army with provisions.

COMMISSION, in common law, the warrant or letters patent, which all persons exercising jurisdiction have to empower them to hear or determine any cause or suit, as the commission of the judges, &c.

COMMISSION of Bankruptcy, is the commission that issues from the lord chancellor, on a person's becoming a bankrupt within any of the statutes, directed to certain commissioners appointed to examine into it,

and to secure the bankrupt's lands and effects for the satisfaction of his creditors. See the article *BANKRUPT*.

The proceedings on a commission of bankruptcy may be divided, 1. Into those which affect the bankrupt himself. 2. Into those which affect his property.

1. As to those of the former kind, there must in the first place be a petition to the lord chancellor by one creditor to the amount of L. 100, or by two to the amount of L. 150, or by three or more to the amount of L. 200; upon which he grants a *commission* to such discreet persons as to him shall seem good, who are then styled commissioners of bankruptcy. The petitioners, to prevent malicious applications, must be bound in a security of L. 200, to make the party amends, in case they do not prove him a bankrupt. And if, on the other hand, they receive any money or effects from the bankrupt, as a recompense for suing out the commission, so as to receive more than their rateable dividends of the bankrupt's estate, they forfeit not only what they shall have so received, but their whole debt. When the commission is awarded and issued, the commissioners are to meet at their own expence, and to take an oath for the due execution of their commission, and to be allowed a sum not exceeding 20s. *per diem* each, at every sitting. And no commission of bankruptcy shall abate or be void on any demise of the crown.

When the commissioners have received their commission, they are first to receive proof of the person's being a trader, and having committed some act of bankruptcy; and then to declare him bankrupt if proved so; and to give notice thereof in the gazette, and at the same time to appoint three meetings. At one of these meetings an election must be made of assignees, or persons to whom the bankrupt's estate shall be assigned, and in whom it shall be vested for the benefit of the creditors; which assignees are chosen by the major part, in value, of the creditors who shall then have proved their debts; but may be originally appointed by the commissioners, and afterwards approved or rejected by the creditors: but no creditor shall be admitted to vote in the choice of assignees, whose debt, on the balance of accounts, does not amount to L. 10. And at the third meeting at farthest, which must be on the 42^d day after the advertisement in the gazette, the bankrupt, upon notice also personally served upon him, or left at his usual place of abode, must surrender himself personally to the commissioners, and must thenceforth in all respects conform to the directions of the statutes of bankruptcy; or, in default thereof, shall be guilty of felony without benefit of clergy, and shall suffer death, and his goods and estate shall be divided among his creditors.

In case the bankrupt absconds, or is likely to run away between the time of the commission issued, and the last day of surrender, he may, by warrant from any judge or justice of the peace, be apprehended and committed to the county goal, in order to be forthcoming to the commissioners, who are also empowered immediately to grant a warrant for seizing his goods and papers.

When

Commis-
sion.

When the bankrupt appears, the commissioners are to examine him touching all matters relating to his trade and effects. They may also summon before them, and examine, the bankrupt's wife, and any other person whatsoever, as to all matters relating to the bankrupt's affairs: And in case any of them shall refuse to answer, or shall not answer fully, to any lawful question, or shall refuse to subscribe such their examination, the commissioners may commit them to prison without bail, till they make and sign a full answer; the commissioners specifying in their warrant of commitment the question so refused to be answered. And any gaoler, permitting such person to escape or go out of prison, shall forfeit L. 500 to the creditors.

The bankrupt upon this examination, is bound, upon pain of death, to make a full discovery of all his estate and effects as well in expectancy as possession, and how he has disposed of the same; together with all books and writings relating thereto: and is to deliver up all in his power to the commissioner; (except the necessary apparel of himself, his wife, and his children); or, in case he conceals or embezzles any effects to the amount of L. 20, or with-holds any books or writings, with intent to defraud his creditors, he shall be guilty of felony without benefit of clergy.

After the time allowed the bankrupt for such discovery is expired, any other person voluntarily discovering any part of his estate before unknown to the assignees, shall be entitled to five *per cent.* out of the effects so discovered, and such farther reward as the assignees and commissioners shall think proper. And any trustee wilfully concealing the estate of any bankrupt, after the expiration of 42 days, shall forfeit L. 100, and double the value of the estate concealed, to the creditors.

Hitherto every thing is in favour of the creditors; and the law seems to be pretty rigid and severe against the bankrupt; but, in case he proves honest, it makes him full amends for all this rigour and severity. For, if the bankrupt hath made an ingenuous discovery, hath conformed to the directions of the law, and hath acted in all points to the satisfaction of his creditors; and if they, or four parts in five of them in number and value, (but none of them creditors for less than L. 20), will sign a certificate to that purport; the commissioners are then to authenticate such certificate under their hands and seals, and to transmit it to the lord chancellor: and he, or two judges whom he shall appoint, on oath made by the bankrupt that such certificate was obtained without fraud, may allow the same; or disallow it, upon cause shewn by any of the creditors of the bankrupt.

If no cause be shewn to the contrary, the certificate is allowed of course; and then the bankrupt is entitled to a decent and reasonable allowance out of his effects, for his future support and maintenance, and to put him in a way of honest industry. This allowance is also in proportion to his former good behaviour, in the early discovery of the decline of his affairs, and thereby giving his creditors a larger dividend. For if his effects will not pay one half of his debts, or 10s. in the pound, he is left to the discretion

Commis-
sion.

of the commissioners and assignees, to have a competent sum allowed him, not exceeding 3 *per cent.*; but if they pay 10s. in the pound, he is to be allowed 5 *per cent.*; if 12s. and 6d. then 7 $\frac{1}{2}$ *per cent.*; and if 15s. in the pound, then the bankrupt shall be allowed 10 *per cent.*; provided that such allowance do not in the first case exceed L. 200, in the second L. 250, and in the third L. 300.

Besides this allowance he has also an indemnity granted him, of being free and discharged forever from all debts owing by him at the time he became a bankrupt; even though judgment shall have been obtained against him, and he lies in prison upon execution for such debts; and, for that among other purposes, all proceedings on commission of bankrupt, are on petition, to be entered on record, as a perpetual bar against actions to be commenced upon this account: though, in general, the production of the certificate properly allowed shall be sufficient evidence of all previous proceedings. Thus the bankrupt becomes a clear man again; and, by the assistance of his allowance and his own industry, may become a useful member of the commonwealth: which is the rather to be expected, as he cannot be entitled to these benefits, but by the testimony of his creditors themselves of his honest and ingenuous disposition; and unless his failures have been owing to misfortunes, rather than to misconduct and extravagance.

2. As to the proceedings which affect the bankrupt's property.

By virtue of the statutes before-mentioned, all the personal estate and effects of the bankrupt, are considered as vested, by the act of bankruptcy, in the future assignees of his commissioners, whether they be goods in actual possession, or debts, contracts, and other choses in action; and the commissioners by their warrant may cause any house or tenement of the bankrupt to be broke open, in order to enter upon and seize the same. And when the assignees are chosen or approved by the creditors, the commissioners are to assign every thing over to them; and the property of every part of the estate is thereby as fully vested in them as it was in the bankrupt himself, and they have the same remedies to recover it.

The property vested in the assignees is the whole that the bankrupt had in himself, at the time he committed the first act of bankruptcy, or that has been vested in him since, before his debts are satisfied or agreed for. Therefore it is usually said, that once a bankrupt, and always a bankrupt: by which is meant, that a plain direct act of bankruptcy once committed, cannot be purged, or explained away, by any subsequent conduct, as a dubious equivocal act may be; but that, if a commission is afterwards awarded, the commission and the property of the assignees shall have a relation, or reference, back to the first and original act of bankruptcy. Inasmuch that all transactions of the bankrupt are from that time absolutely null and void, either with regard to the alienation of his property, or the receipt of his debts from such as are privy to his bankruptcy; for they are no longer his property, or his debts, but those of the future assignees. And if an execution be sued out, but not served and executed

Commis-
sion.

on the bankrupt's effects till after the act of bankruptcy, it is void, as against the assignees. But the king is not bound by this fictitious relation, nor is within the statutes of bankrupts; for if, after the act of bankruptcy committed, and before the assignment of his effects, an extent issues for the debt of the crown, the goods are bound thereby. In France this doctrine of relation is carried to a very great length; for there, every act of a merchant, for 10 days precedent to the act of bankruptcy, is presumed to be fraudulent, and is therefore void. But with us the law stands upon a more reasonable footing: for as these acts of bankruptcy may sometimes be secret to all but a few, and it would be prejudicial to trade to carry this notion to its utmost length, it is provided by stat. 19 Geo. II. c. 32. that no money paid by a bankrupt to a *bona fide*, or real, creditor, in a course of trade, even after an act of bankruptcy done, shall be liable to be refunded. Nor by stat. 1 Jac. I. c. 15. shall any debtor of a bankrupt that pays him his debt without knowing of his bankruptcy, be liable to account for it again. The intention of this relative power being only to reach fraudulent transactions, and not to distress the fair trader.

The assignees may pursue any legal method of recovering this property so vested in them, by their own authority; but cannot commence a suit in *equity*, nor compound any debts owing to the bankrupt, nor refer any matters to arbitration without the consent of the creditors, or the major part of them in value, at a meeting to be held in pursuance of notice in the gazette.

When they have got in all the effects they can reasonably hope for, and reduced them to ready money, the assignees must, within 12 months after the commission issued, give 21 days notice to the creditors of a meeting for a dividend or distribution; at which time they must produce their accounts, and verify them upon oath, if required. And then the commissioners shall direct a dividend to be made, at so much in the pound, to all creditors who have before proved, or shall then prove, their debts. This dividend must be made equally, and in a rateable proportion, to all the creditors, according to the quantity of their debts; no regard being had to the quality of them. Mortgages, indeed, for which the creditor has a real security in his own hands, are entirely safe; for the commission of bankrupt reaches only the equity of redemption. So are also personal debts, where the creditor has a chattel in his hands, or a pledge or pawn, for the payment, or has taken the debtor's lands or goods in execution. And, upon the equity of the stat. 8 An. c. 14. (which directs, that upon all executions of goods being on any premises demised to a tenant, one year's rent and no more shall, if due, be paid to the landlord) it hath also been held, that under a commission of bankrupt, which is in the nature of a statute execution, the landlord shall be allowed his arrears of rent to the same amount, in preference to other creditors, even though he hath neglected to distrein while the goods remained on the premises: which he is otherwise entitled to do for his entire rent be the quantum what it may. But otherwise

judgments and recognizances, (both which are debts of record, and therefore at other times have a priority), and also bonds and obligations by deed or special instrument, (which are called debts by specialty, and are usually the next in order) these are all put on a level with debts by mere simple contract, and all paid *pari passu*. Nay, so far is this matter carried, that, by the express provision of the statutes, debts not due at the time of the dividend made, as bonds or notes of hand, payable at a future day, shall be paid equally with the rest, allowing a discount or drawback in proportion. And insurances, and obligations upon bottomry or respondentia, *bona fide*, made by the bankrupt, though forfeited after the commission is awarded, shall be looked upon in the same light as debts contracted before any act of bankruptcy.

Within 18 months after the commission issued, a second and final dividend shall be made, unless all the effects were exhausted by the first. And if any surplus remains, after paying every creditor his full debt, it shall be restored to the bankrupt. This is a case which sometimes happens to men in trade, who involuntarily, or at least unwarily, commit acts of bankruptcy, by absconding and the like, while their effects are more than sufficient to pay their creditors. And if any suspicious or malevolent creditor will take the advantage of such acts, and sue out a commission, the bankrupt has no remedy, but must quietly submit to the effects of his own imprudence: except that, upon satisfaction made to all the creditors, the commission may be superseded. This case may also happen when a knave is desirous of defrauding his creditors, and is compelled, by a commission, to do them that justice which otherwise he wanted to evade. And therefore, though the usual rule is, that all interest on debts carrying interest shall cease from the time of issuing the commission, yet in case of a surplus left after payment of every debt, such interest shall again revive, and be chargeable on the bankrupt or his representatives.

COMMISSION of Lunacy, issues out of the court of chancery, whether a person represented to be a lunatic, be so or not. See LUNACY.

COMMISSION-Officers. See OFFICERS.

COMMISSION, in commerce. See FACTORAGE.

COMMISSIONER, a person authorized by commission, letters patent, or other lawful warrant, to examine any matters, or execute any lawful commission.

COMMISSIONER in the General Assembly of the church of Scotland. See GENERAL ASSEMBLY.

COMMISSIONERS of the Customs. See CUSTOMS.

COMMISSIONERS of Excise. See EXCISE.

COMMISSIONERS of the Navy. See NAVY.

Lords COMMISSIONERS of the Treasury. See TREASURY and EXCHEQUER.

COMMISSURE, **COMMISSURA**, a term used by some authors, for the small meat's or interstices of bodies; or the little clefts between the particles; especially when those particles are broadish and flat, and lie contiguous to one another, like thin plates or lamellæ. See PORE. The word literally signifies a *joining*, or connecting of one thing to another.

Commis-
sion.

Commis-
sure
Commo-
dore.

COMMISSURE, in architecture, &c. denotes the joint of two stones; or, the application of the surface of the one to that of the other. See MASONRY.

Among anatomists, *commis sure* is sometimes also used for a future of the cranium, or skull. See SUTURE.

COMMITMENT, in criminal law, is the sending to prison a person who hath been guilty of any crime. This takes place where the offence is not bailable, or the party cannot find BAIL; must be by proper warrant, containing the cause of the commitment; and continues till put an end to by the course of law, (see TRIAL); imprisonment being intended only for safe custody, and not for punishment, (see ARRESTMENT and BAIL). In this dubious interval between the commitment and trial, a prisoner ought to be used with the utmost humanity; and neither be loaded with needless fetters or subjected to other hardships than such as are absolutely requisite for the purpose of confinement only: though, what are so requisite, must too often be left to the discretion of the gaolers; who are frequently a merciless race of men, and, by being conversant in scenes of misery, steeled against any tender sensation.

COMMITMENT of Bankruptcy. See COMMISSION of Bankruptcy.

COMMITTEE, one or more persons to whom the consideration or ordering of a matter is referred, either by some court, or by the consent of parties to whom it belongs.

COMMITTEE of Parliament, a certain number of members appointed by the house, for the examination of a bill, making a report of an inquiry, process of the house, &c. See PARLIAMENT.

COMMIXION, in Scots law, is a method of acquiring property, by mixing or blending together different substances belonging to different proprietors. See LAW, Part III. N^o cxlii. 8.

COMMODATE, COMMODATUM, in the civil jurisprudence, the loan, or free concession of any thing moveable or immoveable, for a certain time, on condition of restoring again the same individual after a certain term. The *commodate* is a kind of loan: there is this difference, however, between a loan and a *commodate*, that the latter is gratis, and does not transfer the property: the thing must be returned in essence, and without impairment: so that things which consume by use, or time, cannot be objects of a *commodate*, but of a loan; in regard they may be returned in kind, though not in identity. See LAW, Part III. N^o dxxiii. 8.

COMMODIANUS (Gazeus), a Christian author in the 4th century, who wrote a work in Latin verse, intitled Instructions; the moral of which is excellent, but the verse extremely heavy. M. Davies published a fine edition of it, in 1711, at the end of Minucius Felix.

COMMODITY, in a general sense, denotes all sorts of wares and merchandizes whatsoever, that a person deals or trades in.

Staple COMMODITIES, such wares and merchandizes as are commonly and readily sold in a market, or exported abroad; being, for the most part, the proper produce, or manufacture of the country.

COMMODORE, a general officer in the British ma-

rine, invested with the command of a detachment of ships of war defined on any particular enterprise, during which time he bears the rank of brigadier-general in the army, and is distinguished from the inferior ships of his Squadron by a broad red pendant tapering towards the outer-end, and sometimes forked. The word is corrupted from the Spanish, *comendador*.

COMMODORE, is also a name given to some select ship in a fleet of merchantmen, who leads the van in time of war, and carries a light in his top to conduct the rest, and keep them together.

COMMON, COMMUNIS, something that belongs to all alike; is owned or allowed by all; and not confined to this more than that. In which sense, *common* stands opposed to *proper*, *peculiar*, &c. Thus, the earth is said to be our *common* mother; in the first, or golden age, all things were in *common*, as well as the sun and elements: the name animal is *common* to man and beast; that of substance to body and spirit.

COMMON Council. See COUNCIL.

COMMON Law, that body of law received as rules in these kingdoms, before any statute was enacted in parliament to alter the same. See LAW, Part II. n^o 36.

COMMON-PLACE Book, is a register of what things occur, worthy to be noted, in the course of a man's thinking or study, so disposed, as that, among a number of subjects any one may be easily found. The advantages of making a common-place book are many: it not only makes a man read with accuracy and attention, but induces him insensibly to think for himself, provided he considers it not so much as a register of sentiments that strike him in the course of reading, but as a register of his own thoughts upon various subjects. Many valuable thoughts occur even to men of no extraordinary genius. These, without the assistance of a common place-book, are generally lost both to himself and others. There are various methods of arranging common-place books; that of Mr Locke is as good as any that have hitherto been contrived.

The first page of the book you intend to take down their *common-place* in, is to serve as a kind of index to the whole; and to contain references to every place or matter therein: in the commodious contrivance of which index, so as it may admit of a sufficient copia or variety of materials, without any confusion, all the secret of the method consists.

In order to this, the first page, as already mentioned, or, for more room, the two first pages that front each other, are to be divided, by parallel lines, into 25 equal parts; whereof, every 5th line to be distinguished, by its colour or other circumstance. These lines are to be cut perpendicularly by others, drawn from top to bottom; and in the several spaces thereof, the several letters of the alphabet, both capital and minuscule, are to be duly wrote.

The form of the lines and divisions, both horizontal and perpendicular, with the manner of writing the letters therein, will be conceived from the following specimen; wherein, what is to be done in the book for all the letters of the alphabet, is here shewn in the first four, *A, B, C, and D*.

The index of the common-place book thus formed, matters are ready for the taking down any thing therein.

In order to this, consider to what head the thing you would enter is most naturally referred; and under which one would be led to look for such a thing: in this head, or word, regard is had to the initial letter, and the first vowel that follows it; which are the characteristic letters whereon all the use of the index depends.

Suppose (*e. gr.*) I would enter down a passage that refers to the head *beauty*; *B*, I consider, is the initial letter, and *e* the first vowel: then, looking upon the index for the partition *B*, and therein the line *e*, (which is the place for all words whose first letter is *b*, and first vowel *e*; as *beauty*, *beneficence*, *bread*, *breeding*, *blemishes*), and finding no numbers already down to direct me to any page of the book where words of this characteristic have been entered, I turn forward to the first blank page I find, (which, in a fresh book, as this is supposed to be, will be page 2^d), and here write what I have occasion for on the head *beauty*; beginning the line in the margin, and indenting all the other subservient lines, that the head may stand out and shew itself: this done, I enter the page where it is wrote, *viz.* 2, in the index in the space *B e*; from which time, the class *b e* becomes wholly in possession of the 2^d and 3^d pages, which are assigned to letters of this characteristic.

Had I found any page or number already entered in the space *B e*, I must have turned to the page, and have wrote my matter in what room was left therein: so, if after entering the passage on *beauty*, I should have occasion for *benevolence*, or the like, finding the number 2 already possessed of the space of this characteristic, I begin the passage on *benevolence* in the remainder of the page, which not containing the whole, I carry it on to page 3^d, which is also for *b e*; and add the number 3 in the index.

COMMON *Pleas*, is one of the king's courts now held constantly in Westminister-hall, but in former times was moveable.

All civil causes, as well real as personal, are, or were formerly, tried in this court, according to the strict law of the land. In personal and mixed actions it has a concurrent jurisdiction with the king's bench, but has no cognizance of pleas of the crown. The actions belonging to the court of common pleas come thither by original, as arrests and outlawries; or by privilege, or attachment for or against privileged persons; or out of inferior courts, not of record, by *pone*,

recordari, *accedas ad curiam*, writ of false judgment, &c. The chief judge of this court is called lord Chief Justice of the common pleas, who is assisted by three other judges: the other officers of the court are the *custos brevium*, who is the chief clerk; three prothonotaries, and their secondaries; the clerk of the warrants, clerk of the *essoins*, 14 filazers, 4 exigentors, a clerk of the juries, the chirographer, the clerk of the king's silver, clerk of the treasury, clerk of the seal, clerk of the outlawries, clerk of the inrolment of fines and recoveries, and clerk of the errors.

COMMON, in law, that soil, the use of which is common to this or that town or lordship. There is common of pasture for cattle; and also common of fishing; common of estovers; common of turbary, &c.

COMMON-Prayer is the liturgy in the church of England: see LITURGY. Clergymen are to use the public form of prayers prescribed by the Book of Common Prayer; and refusing to do so, or using any other public prayers, are punishable by stat. 1 Eliz. c. ii.

COMMON, in grammar, denotes the gender of nouns, which are equally applicable to both sexes: thus, *parens*, "a parent," is of the common gender.

COMMON, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures:

COMMON *Divisor*, a quantity or number which exactly divides two or more other quantities or numbers, without leaving any remainder.

COMMONALTY, the lower of the two divisions of the civil state. See CIVIL State.

The commonalty, like the nobility, are divided into several degrees: and as the lords, though different in rank, yet all of them are peers in respect of their nobility; so the commoners, though some are greatly superior to others, yet all are in law commonalty, in respect of their want of nobility.

1. The first name of dignity, next beneath a peer, was anciently that of *vidames*, *vice-domini*, or *valou-fors*: who are mentioned by our ancient lawyers, as *vir* magnæ dignitatis; and Sir Edward Coke speaks highly of them. Yet they are now quite out of use; and our legal antiquarians are not agreed upon even their original or ancient office.

2. Now, therefore, the first personal dignity, after the nobility, is a knight of the order of St George, or of the garter; first instituted by Edw. III. A.D. 1344.

3. Next, (but not till after certain official dignities, as privy-counsellors, the chancellors of the exchequer and duchy of Lancaster, the chief justice of the king's bench, the master of the rolls, and the other English judges), follows a *knicht banneret*; who indeed, by statutes

statutes 5 Richard II. stat. 2. c. 4. and 14 Richard II. c. 11. is ranked next after barons; and his precedence before the younger sons of viscounts, was confirmed to him by order of king James I. in the 10th year of his reign. But in order to entitle him to this rank, he must have been created by the king in person, in the field, under the royal banners, in time of open war; else he ranks after

4. *Baronets*; who are the next in order: which title is a dignity of inheritance, created by letters patent, and usually descendible to the issue-male. It was first instituted by king James I. A. D. 1611, in order to raise a competent sum for the reduction of the province of Ulster in Ireland; for which reason all baronets have the arms of Ulster superadded to their family-coat.

5. Next follow *knights of the Bath*; an order instituted by king Henry IV. and revived by king Geo. I. They are so called from the ceremony of bathing the knight before their creation.

6. The last of these inferior nobility are *knights bachelor*; the most ancient, though the lowest, order of knighthood amongst us: for we have an instance of king Alfred's conferring this order on his son Athelstan.

7. The above, with those enumerated under the article NOBILITY, Sir Edward Coke says, are all the names of *dignity* in this kingdom; *esquires* and *gentlemen* being only names of *worship*. But before these last the heralds rank all colonels, serjeants at law, and doctors in the three learned professions.

8. *Esquires* and *gentlemen* are confounded together by Sir Edward Coke; who observes, that every esquire is a gentleman, and a gentleman is defined to be one *qui arma gerit*, "who bears coat-armour," the grant of which adds gentility to a man's family: in like manner as civil nobility among the Romans was founded in the *ius imaginum*, or having the image of one ancestor at least who had borne some curule office. It is indeed a matter somewhat unsettled what constitutes the distinction, or who is a real esquire; for it is not an estate, however large, that confers this rank upon its owner. Camden, who was himself a herald, distinguishes them the most accurately; and he reckons up four sorts of them: 1st, The eldest sons of knights, and their eldest sons, in perpetual succession. 2^d, The eldest sons of younger sons of peers, and their eldest sons, in like perpetual succession: both which species of esquires, Sir Henry Spelman intitles *armigeri natalitii*. 3^d, Esquires created by the king's letters patent, or other investiture; and their eldest sons. 4th, Esquires by virtue of their office; as justices of the peace and others who bear any office of trust under the crown. To these may be added the esquires of the knights of the bath, each of whom constitutes three at his installation; and all foreign, nay, Irish peers; for not only these, but the eldest sons of peers of Great Britain, though frequently titular lords, are only esquires in the law, and must be so named in all legal proceedings.

9. As for *gentlemen*, says Sir Thomas Smith, they be made good cheap in this kingdom: for whosoever studieth the laws of the realm, who studieth in the universities, who professeth liberal sciences, and (to be

short) who can live idly and without manual labour, Commoner
1 Commons.
and will bear the part, charge, and countenance of a gentleman, he shall be called master, and shall be taken for a gentleman.

10. A *yeoman* is he that hath free land of 40 s. by the year; who is thereby qualified to serve on juries, vote for knights of the shire, and do any other act where the law requires one that is *probus et legalis homo*.

11. The rest of the commonalty are *tradesmen, artificers, and labourers*; who (as well as all others) must, in pursuance of the statute 1 Henry V. c. 5. be styled by the name and addition of their estate, degree or mystery, in all actions and other legal proceedings.

COMMONER, or GENTLEMAN-COMMONER, in the universities, a student entered in a certain rank.

COMMONS, or HOUSE OF COMMONS, a denomination given to the lower house of parliament. See PARLIAMENT.

The commons consist of all such men of any property in the kingdom, as have not seats in the house of lords, every one of which has a voice in parliament, either personally, or by his representatives. In a free state every man, who is supposed a free agent, ought to be, in some measure, his own governor; and therefore a branch at least of the legislative power should reside in the whole body of the people. And this power, when the territories of the state are small, and its citizens easily known, should be exercised by the people in their aggregate or collective capacity, as was wisely ordained in the petty republics of Greece, and the first rudiments of the Roman state. But this will be highly inconvenient when the public territory is extended to any considerable degree, and the number of citizens is increased. Thus when, after the social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public assemblies, it became impossible to distinguish the spurious from the real voter, and from that time all elections and popular deliberations grew tumultuous and disorderly; which paved the way for Marius and Sylla, Pompey and Cæsar, to trample on the liberties of their country, and at last to dissolve the commonwealth. In so large a state as ours, therefore, it is very wisely contrived, that the people should do that by their representatives, which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, where in all the voters are or may be easily distinguished. The counties are therefore represented by knights, elected by the proprietors of lands; the cities and boroughs are represented by citizens and burghesses, chosen by the mercantile or supposed trading interest of the nation; much in the same manner as the burghers in the diet of Sweden are chosen by the corporate towns, Stockholm sending four, as London does with us, other cities two, and some only one. The number of English representatives is 513, of Scots 45; in all 558. And every member, though chosen by one particular district, when elected and returned, serves for the whole realm. For the end of his coming thither is not particular but general; not barely to advantage his constituents, but the commonwealth; to advise his majesty, as appears from the writ of summons,

Commons
|
Communi-
cation.

mons, "de communi consilio super negotiis quibufdam arduis et urgentibus, regem, statum et defensionem regni Angliæ et ecclesiæ Anglicanæ concernentibus." And therefore he is not bound, like a deputy in the united provinces, to consult with, or take the advice of, his constituents upon any particular point, unless he himself thinks it proper or prudent to do so.

The peculiar laws and customs of the house of commons relate principally to the raising of taxes, and the elections of members to serve in parliament. See TAXES and ELECTIONS.

Doctors Commons. See COLLEGE of civilians.

Proctor of the Commons. See PROCTOR.

COMMONTY, in Scots law, sometimes signifies lands belonging to two or more common proprietors; sometimes a heath or muir though it should belong in property to one, if there has been a promiscuous possession upon it by pasturage; and the act 1695 mentions commonities belonging in property to the king and to royal boroughs. See LAW, Part III. N^o cxxxv. 16.

COMMONWEALTH. See REPUBLIC.

COMMOTE, an ancient term in Wales, denoting half a cantred, or hundred; containing 50 villages. See HUNDRED. Wales was anciently divided into three provinces; each of these subdivided into cantreds; and every cantred into two commotes or hundreds. Silvester Girald, however, tells us in his itinerary, that a commote is but a quarter of a hundred.

COMMUNES, in botany, the name of a class in Linnæus's *methodus Calycina*, consisting of plants which, like teasel and dandelion, have a calix or flower-cup common to many flowers or florets. These are the aggregate or compound flowers of other systems.

COMMUNIBUS LOCIS, a Latin term, in frequent use among philosophical, &c. writers; implying some medium, or mean relation, between several places. Dr Keil supposes the ocean to be one quarter of a mile deep, *communibus locis*, *q. d.* at a medium, or taking one place with another.

COMMUNIBUS ANNIS, has the same import with regard to years, that communibus locis has with regard to places. Mr Derham observes that the depth of rain, *communibus annis*, or one year with another, were it to stagnate on the earth, would amount in Townley in Lancashire, to 42½ inches; at Upminster in Essex, to 19½; at Zurich, 32½; at Pisa, 43½; and at Paris to 19 inches.

COMMUNICATION, in a general sense, the act of imparting something to another.

COMMUNICATION is also used for the connection of one thing with another, or the passage from one place to another: thus a gallery is a communication between two apartments.

COMMUNICATION of motion, the act whereby a body at rest is put into motion by a moving body; or, it is the acceleration of motion in a body already moving.

Lines of Communication, in military matters, trenches made to continue and preserve a safe correspondence between two forts or posts; or at a siege,

between two approaches, that they may relieve one another.

Canal of Communication. See CANAL.

COMMUNION, in matters of religion, the being united in doctrine and discipline; in which sense of the word, different churches are said to hold communion with each other.

In the primitive Christian church, every bishop was obliged, after his ordination, to send circular letters to foreign churches, to signify that he was in communion with them. The three grand communions into which the Christian church is at present divided, is that of the church of Rome, the Greek church, and the Protestant church: but originally all Christians were in communion with each other, having one common faith and discipline.

COMMUNION is also used for the act of communicating in the sacrament of the eucharist, or the Lord's supper. See RELIGION.

COMMUNION Service, in the liturgy of the church of England, the office for the administration of the holy sacrament, extracted from several ancient liturgies, as those of St Basil, St Ambrose, &c.

By the last rubric, part of this service is appointed to be read every Sunday and holiday, after the morning prayer, even though there be no communicants.

COMMUNITY, a society of men living in the same place, under the same laws, the same regulations, and the same customs.

COMMUTATION in law, the change of a penalty or punishment from a greater to a less; as when death is commuted for banishment, &c.

COMMENA (Ann) daughter of Alexis Comnenes emperor of the East; memorable for her great learning and virtue, and for her history of the life and actions of her father, which is highly esteemed. She flourished about the year 1117.

COMO, a strong and populous town of Italy, in the duchy of Milan, and in the Comasco, with a bishop's see. It was taken by the Imperialists in 1706, and is seated on a lake of the same name in E. Long. 8. 57. N. Lat. 45, 45.

Como, the lake so called, is the largest in Italy. It is situated in the duchy of Milan in the Comasco, on the confines of Swisserland and the Grisons. It is 88 miles in circumference, yet is not above 6 miles over in any part.

COMORA islands, lie between the north end of the island of Madagascar, and the coast of Zanguebar, from 10 to 15 degrees south latitude. Authors differ greatly with regard to their number, some speaking of three, others of five, and some of eight of these islands. They all abound in horned cattle, sheep, hogs, and a variety of fruits common in warm countries. They are said also to produce a kind of rice which turns of a violet colour when boiled. The most remarkable of them, and which the Europeans are best acquainted with, is the island of Johanna. See that article.

COMORIN, or CAPE COMORIN, the most southerly promontory of the bither India, lying north-west of the island of Ceylon.

COMORRA, a handsome and large town of lower Hungary, and capital of a territory of the same name.

Communi-
cation
|
Commora.

name. It is so well fortified, that the Turks could never take it. The greatest part of the inhabitants are Hungarians or Ruffians, who are very rich, and are of the Greek religion. It is seated on the river Danube, in the island of Sihut, E. Lon. 18. 25. N. Lat. 47. 50.

COMOSÆ, in botany, from *Coma*. An order of plants in the former editions of Linnæus's Fragments of a Natural Method, consisting of the spiked willow or *Spiræa frutex*, dropwort, and greater meadow-sweet. These, though formerly distinct genera, are by Linnæus collected into one, under the name of *Spiræa*. The flowers, growing in a head, resemble a bush, or tuft of hair, which probably gave rise to the epithet *Comosæ*.

COMPACT, in philosophy, is said of bodies which are of a close, dense, and heavy texture, with few pores, and those very small.

COMPACT, in a legal sense, signifies an agreement, or contract stipulated between several parties.

COMPANY, in a commercial sense, is a society of merchants, mechanics, or other traders, joined together in one common interest. The word is formed of the French *compagnie*, and that of *compagnie*, or *compagnis*, which Chifflet observes, are found in the Salique law, tit. 66, and are properly military words, understood of soldiers, who, according to the modern phrase, are comrades or mess-mates, *i. e.* lodge together, eat together, &c. of the Latin *cum* "with," and *panis* "bread." It may be added, that in some Greek authors, under the western empire, the word *Κατωσανα* occurs in the sense of *society*; but it is more probable that the Greeks borrowed it from the French or Italians.

When there are only two or three joined in this manner, it is called a partnership; the term *company* being restrained to societies consisting of a considerable number of members, associated together by a charter obtained from the prince.

The mechanics of all corporations, or towns incorporated, are thus erected into companies, which have charters of privileges and large immunities.

We shall here give some account of the principal companies of merchants, some of which trade with joint stocks, and all of them enjoy by charter many exclusive privileges. For, however injurious these companies may, at this time of day, be reckoned to the nation in general, yet it is certain, that they were the original parents of all our foreign commerce; private traders upon their own bottom being discouraged from hazarding their fortunes in foreign countries, till the methods of traffic had been settled by joint-stock companies: and from this very principle it is, that we find several nations at present endeavouring to extend their trade by the same means. The most ancient trading company, in Britain, is the Hamburgh company, originally called *merchants of the Staple*, and afterwards *merchant adventures*: they were incorporated by king Edward IV. from which time they traded with success till the reign of queen Elizabeth, who, for a further encouragement of their industry, not only confirmed, but enlarged their privileges. However, it ought to be observed, that this trade is now open to private merchants, upon paying a very small sum to the company. The company of this kind, next

Company. incorporated, was that of the Russia-merchants; who having improved their trade and commerce in those remote parts, were incorporated by Edward VI. greatly encouraged by queen Mary, and had their confirmation, with an enlargement of their privileges, from Elizabeth. This company is not very considerable at present; the trade of those parts being mostly carried on by private merchants, on paying the sum of 5*l.* to the company.

The Eastland company, formerly called merchants of Elbin, were incorporated by queen Elizabeth, and by her greatly encouraged; but, like the former company, it is now become inconsiderable, the trade of Norway and Sweden being laid open by act of parliament.

The Turkey, or Levant company, was likewise incorporated by the same prince, and its charter confirmed and enlarged by king James I. who empowered them to trade to the Levant, or eastern parts of the Mediterranean; particularly to Smyrna, Aleppo, Alexandria, Grand-Cairo, and the other parts of the Turkish dominions. But this trade is now also laid open to private merchants, upon paying a small consideration.

The next in order is the East-India company, first incorporated in the year 1600, and empowered to trade to all countries lying eastward of the cape of Good Hope. Towards the end of king William's reign, an act of parliament passed, granting all private merchants, who should raise a certain sum for the supply of the government, the privilege of trading to these parts. Accordingly, a great many subscribed, and were called the New East-India company; which soon found it necessary to unite with the old one, and trade with one joint stock: since which time, they have been styled the united East-India company; and are at present in a flourishing condition, and in possession of many considerable forts and factories on the coast of Malabar, the Coromandel-coast, the bay of Bengal, &c.

The royal African company was first erected in the year 1661, with an exclusive privilege to trade from cape Blanc, on the coast of Africa, in 20° N. Lat. as far as the cape of Good Hope. But this trade is now laid open by act of parliament.

The Eastland company, the Greenland company, the Hudson's-bay company, the South-sea company, have likewise their several charters and privileges for trading to the places from which they take their denominations.

These are the principal trading companies belonging to the crown of Great Britain; and of a similar nature are the Dutch East and West India companies, the French East and West India companies, &c.

Concerning these companies, it may be proper to remark, that however necessary they might be in the infancy of trade, they are now looked upon by most men in the light of monopolies: hence it is, that their privileges have from time to time been lessened, in order to establish an absolutely free and general trade; and experience hath shewn, that the trade of the nation has advanced in proportion as monopolies have been laid aside. Indeed, to carry on trade with distant countries, where forces and forts are to be maintained, a company with a joint stock seems necessary;

er, at least, certain duties ought to be paid by all who trade thither, towards defraying the said expences: for not to speak of the East-India, Hudson's-bay, &c. companies, the expence of maintaining whole forts must be very considerable, even the Hurky, Hamburgh, Moscow, and Eastland companies, which do not trade with a joint stock, are nevertheless obliged to be at considerable charges, in making presents to the grand signior and his ministers, maintaining consuls, &c. It would therefore be unjust that any should trade to the places within their charters, without paying the same duties toward's the company's charge, as the present adventurers pay; but then there appears to be no reason why any of the king's subjects should be barred from trading to those places, or forced to pay a great fine for admission, that are willing to pay the company's duties, and submit to their regulations and orders in other respects.

On the whole, as all restrictions of trade are found to be hurtful, nothing can be more evident than that no company whatsoever, whether they trade in a joint stock, or only under regulation, can be for the public good, except it may be easy for all or any of his majesty's subjects to be admitted into all or any of the

said companies, at any time, and for a very inconsiderable fine.

COMPANY, in military affairs, a small body of foot, commanded by a captain, who has under him a lieutenant and ensign.

The number of centinels or private soldiers in a company, may be from 50 to 80; and a battalion consists of 13 such companies, one of which is always grenadiers, and posted on the right; next them stand the eldest company, and on the left the second company; the youngest one being always posted in the centre. Companies not incorporated into regiments are called irregulars, or independent companies.

Artillery COMPANY. See ARTILLERY.

COMPANY OF SHIPS, a fleet of merchantmen, who make a charter party among themselves; the principal conditions whereof usually are, that certain vessels shall be acknowledged admiral, vice-admiral, and rear-admiral; that such and such signals shall be observed; that those which bear no guns, shall pay so much *per cent.* of their cargo; and in case they be attacked, that what damages are sustained, shall be reimbursed by the company in general. In the Mediterranean, such companies are called *confreres*.

COMPARATIVE ANATOMY

IS that branch of anatomy which considers the secondary objects, or the bodies of other animals; serving for the more accurate distinctions of several parts, and supplying the defect of human subjects.

It is otherwise called the anatomy of beasts, and sometimes zootomy; and stands in contradistinction to human anatomy, or that branch of the art which considers the human body, the primary object of anatomy. See ANATOMY.

INTRODUCTION.

¹ THE principal advantages of comparative anatomy are the following: first, it furnishes us with a sufficient knowledge of the different parts of animals, to prevent our being imposed upon by those authors who have delineated and described several parts from brutes as belonging to the human body. Secondly, it helps us to understand several passages in the ancient writers in medicine, who have taken many of their descriptions from brutes and reasoned from them. The third and great use we reap from this science, is the light it casts on several functions in the human œconomy, about which there have been so many disputes among anatomists.

² In this view it is altogether needless to insist on those parts whose use is easily understood when once their structure is unravelled; thus for instance, if we be acquainted with the action of the muscles in general, it will not be difficult to determine the use of any particular muscle, whose origin and insertion is known, if we at the same time consider the various connections of the bones to which it is fixed, and the different degree of mobility they have with respect to each other: in the same manner if we know the use of the nerves in general, we can easily assign the use

of those nerves which are distributed to any particular part. There is then no occasion for a complete osteology, myology, &c. of the several animals we shall treat of, nor need we trouble ourselves about the structure of any of the parts, unless when it serves to illustrate some of the fore-mentioned purposes.

That the first use we proposed from examining the structure of the parts in brutes is real and of consequence, is evident from looking into the works of some of the earliest and greatest masters of anatomy, who for want of human subjects have often borrowed their descriptions from other animals. The great Vesalius, although he justly reproves Galen for this fault, is guilty of the same himself, as is plain from his delineations of the kidneys, uterus, the muscles of the eye and some other parts. Nor is antiquity only to be charged with this, since in Willis's *Anatomia Cerebri* (the plates of which were revised by that accurate anatomist Dr Lower) there are several of the pictures taken from different brutes, especially the dog, besides those he owns to be such. We shall give several examples of the second use in the sequel of the work.

The animal kingdom, as well as the vegetable, contains the most surprising variety, and the descent in each is so gradual, that the little transitions and deviations are almost imperceptible. The bat and flying-squirrel, though quadrupeds, have wings to buoy themselves up in the air. Some birds inhabit the waters, and there are fishes that have wings, and are not strangers to the airy regions; the amphibious animals blend the terrestrial and aquatic together.

As there is then such a vast variety, it is not only needless but impossible to consider all of them particularly. We shall take only some of the most remarkable genera, and hope from what will be said of them

³ The variety and uniformity observable in nature.

¹ The uses of Comparative Anatomy.

² How the action of muscles is determined.

them, any of the intermediate degrees may be understood.

4
Division of animals into quadrupeds, volatiles, fishes, and insects,

In treating of quadrupeds, we shall divide them into the carnivorous, *i. e.* those that feed indifferently on animal and vegetable substances, and granivorous: as an instance of these last we shall take the ruminant kind. The fowls we shall also divide into those that feed on grain, and those that feed on flesh. The distinction we shall make in treating of fishes, shall be of those that have lungs, and those that have them not. The first indeed are with difficulty procured, and at the same time differ very little from quadrupeds. As the structure of insects is so very minute, and lends us but little assistance for the ends proposed, we purposely omit them.

In inquiring into the structure of different animals, we ought to be previously acquainted with the form of their body, manner of life, kind of food; or in short, with their natural history, which will lead us to account for the reason of their different structure, and thence explain the actions of the human body.

CHAP. I. Of Quadrupeds in general.

ALL quadrupeds have a covering of hair, wool, &c. to defend them from the injuries of the weather, which varies in thickness according to the season of the year, and difference of the climate: thus in Russia and the northern countries, the furs are very thick and warm, while the little Spanish lap-dogs, and Barbary cows, have little or no hair at all.

5
Cuticula, cutis, panniculus carnosus.

The cutis and cuticula in quadrupeds, are disposed much in the same way as the human, only more elastic; immediately under this, there is a very thin cutaneous muscular substance called *panniculus carnosus*, which is common to all quadrupeds, the porcine kind excepted; this principally covers the trunk, serving to shrivel the skin, in order to drive off insects, their tails and heads not being sufficient for this purpose, while their extremities are employed in their support and progression.

6
Whence the notion of the panniculus carnosus, &c.

It has probably been from observing some muscles of the human body, such as the *platysma myoides*, *cremaster*, and *frontales*, and the collapsed tunica cellulosa of emaciated subjects, to resemble this thin muscle, that some of the older anatomists reckoned such a panniculus among the common teguments of the human body. This Carolus Stephanus has well observed,

7
Why most quadrupeds want clavicles.

Most part of quadrupeds want clavicles, whereby their anterior extremities fall upon their chest, so as to make their thorax proportionally narrower than the human. This small distance of their anterior extremities is very necessary for their uniform progression: apes indeed and squirrels have clavicles to allow them a more full use of their extremities in climbing, but when they sit down on all-four they walk but indifferently.

CHAP. II. The Anatomy of a Dog.

WE may first observe of this animal, as indeed of most quadrupeds, that its legs are much shorter in proportion to its trunk than in man, the length of whose steps depends entirely on the length of his inferior extremities; however, to balance this, the trunk of the animal is proportionally longer and smaller, his spine more flexible, by which he is able at each step to bring his po-

sterior extremities nearer to his anterior. His common teguments are much a-kind to those of other quadrupeds, only they allow little or no passage for sweat, but when he is over-heated the superfluous matter finds an exit by the salivary glands, for he lolls out his tongue and flavers plentifully.

The pyramidal muscles are wanting, to supply which the rectus is inserted fleshy into the os pubis.

The omentum reaches down to the os pubis, which considering the posture of the animal we will find to be a wise provision, since its use is to separate an oily liquor for lubricating the guts and facilitating their peristaltic motion; so in our erect posture the natural gravity of the oil will determine it downward, but in the horizontal position of these creatures, if all the intestines were not covered, there would be no favourable derivation of the fluid to the guts lying in the posterior part of the abdomen, which is the highest; and besides, had the omentum reached much farther down in us, we had been in continual hazard of an epiplocele, which the dog is not subject to as his viscera do not press so much on the rings of the abdominal muscles. The inferior and anterior lamella of the omentum is fixed to the spleen, fundus of the stomach, pylorus, liver, &c. in the same way as the human, but the superior having no colon to pass over, goes directly to the back-bone. This serves to explain the formation of the final omentum in the human body, which is nothing but the large omentum, having lost its fat, passing over the stomach and colon, where it reassumes its pinguedo, so proceeds and is firmly attached to the liver, spine, &c. The triæ of fat are pretty regularly disposed through it, accompanying the distribution of the blood-vessels to guard them from the pressure of the super-incumbent viscera.

This animal's stomach, though pretty much resembling the human in its shape, is somewhat differently situated. It lies more longitudinal, as indeed all the other viscera do to accommodate themselves to the shape of the cavity in which they are contained, that is, its inferior orifice is much farther down with respect to the superior than the human; by this means the gross food has an easier passage into the duodenum. Again, the fundus of the human stomach, when distended, stands almost directly forwards, which is occasioned by the little omentum tying it so close down to the back-bone, &c. at its two orifices, but it not being fixed in that manner in the dog, the fundus remains always posterior: this also answers very well the shape of the different cavities, the distance betwixt the cardia and fundus being greater than that betwixt the two sides. It seems to be much larger in proportion to the bulk of the animal than the human, that it might contain a greater quantity of food at once, which was very necessary, since this animal cannot at any time get its sustenance as men do. The turbilion is not so large, nor is there any coercion forming the antrum Willisii as in the stomach of man. It is considerably thicker and more muscular than ours for breaking the cohesion of their food, which they swallow without sufficient chewing. Hence it is evident the force of the stomach is not so great as some have supposed, nor its contraction so violent; otherwise that of dogs would be undoubtedly wounded by the

[8]
Abdomen, musculi pyram.

8
Ventriculus.

sharp bones, &c. they always take down; for the contraction here is still greater than in the human stomach, which is much thinner. The rugæ of the tunica villosa are neither so large nor situated transversely as in the human, but go from one orifice to the other; the reason of which difference is, perhaps, that they might be in less danger of being hurt by the hard substances this creature frequently feeds upon; and for the same reason there is not the like coercion at their pylorus.

9
Intestines.

The intestines of this animal are proportionally much shorter than ours; for the food which these creatures mostly use, soon dissolves and then putrifies; on which account there was no occasion for a long tract of intestines, but on the contrary that it should be quickly thrown out of the body: the same is to be observed of all the carnivorous animals. The muscular coat of the intestines is also stronger than the human, to protrude the hard bones, lest they should stop somewhere in the canal.

10
Duodenum.

The valvulæ conniventes are less numerous, and in a longitudinal direction.

11
Jejunum.

The duodenum differs considerably in its situation from the human; for in man it first mounts from the pylorus upwards, backwards, and to the right-side, then passes down by the gall-bladder, and marching over the right-kidney and superior part of the psoas muscles, makes a curvature upwards, and passes over the back-bone and vena cava inferior, to the left hypochondrium, where it gets through the omentum, mesentery and mesocolon to commence jejunum, being firmly tied down all the way, the biliary and pancreatic ducts entering at its most depending part: whereas in the dog the duodenum is fixed at the pylorus to the concave surface of the liver, and hangs loose and pendulous with the mesentery backwards into the cavity of the abdomen, then turning up again is fixed to the back-bone, where it ends in the jejunum; the bile and pancreatic juice are poured into it at the most depending part; therefore the same intention seems to have been had in view in the formation of this part in both, *viz.* the giving the chyle, after the liquors of the liver and pancreas are poured into it, a disadvantageous course, that so it might be the more intimately blended with the humours before its entry into the jejunum, where the lacteals are very numerous: and this by reason of their different posture, the same design (though by a very different order of the parts), is brought about in both.

12
Intestina tenuia.

The other small guts are much the same with ours, only shorter. The great guts are also shorter and less capacious than in the human body; and we take it for a general rule, that all animals that live on vegetable food, have not only their small guts considerably longer, but also their great guts more capacious than such creatures as feed on other animals. Hence man from this form of his intestines and that of the teeth, seems to have been originally designed for feeding on vegetables, and still the most of his food is of that class.

The reason of this difference seems to be, that as animal food is not only much more easily reduced into chyle, but also more prone to putrefaction, too long a remora of the juices might occasion the worst consequences. So it was necessary that their recep-

tacles should not be too capacious, but on the contrary, being short and narrow, might conduce to the seasonable discharge of their contents. Whereas vegetable food being more difficultly dissolved and converted into an animal nature, there was a necessity for such creatures as feed on it to be provided with a long internal canal, that this food in its passage might be considerably retarded, and have time to change its indoles into one more agreeable to our nature. Besides which, there is another advantage which accrues to man in particular, from having his great guts very capacious; for as he is a rational being, and mostly employed in the functions of social life, it would have been very inconvenient, as well as unbecoming for him to be too frequently employed in such ignoble exercises, so that having this large reservoir for his fæces alvine, he can retain them for a considerable time without any trouble.

The appendix vermiformis justly enough deserves the name of an *intestinum cecum* in this subject, though in the human body it does not, and it has probably been from the largeness of this part in other animals, that the oldest anatomists came to reckon that small appendiculus in man as one of the great guts: on its internal surface we observe a great number of mucous glands.

The colon has no longitudinal ligaments, and consequently this gut is not purled up into different bags or cells as the human; nor does this intestine make any circular turn round the abdomen, but passes directly across it to the top of the os sacrum, where it gets the name of rectum.

At the extremity of the *intestinum rectum* or verge of the anus, there are found two bags or pouches which contain a most abominable fetid mucus for which the use is not known, unless it serves to lubricate the strained extremity of the rectum, and defend it against the asperity of the fæces, or to separate some liquor that might otherwise prove hurtful to their bodies. There is nothing analogous to those sacs in the human subject, unless we reckon on the mucilaginous glands that are found most frequent and largest about the lower part of the rectum.

The mesentery is considerably longer than in the human body; for in man had the mesentery been very long, the guts would have fallen down on the stomach, &c. by reason of his erect position. The fat is here disposed in the same way, and for the same reason, as in the omentum. The interstices betwixt the fat are filled with a fine membrane. Instead of a great number of glandular vassæ to be found in the human mesentery, there is only one large gland to be observed in the middle of the mesentery of a dog, which from its imagined resemblance to the pancreas and the name of its discoverers, is called *pancreas asellii*. The reason why this in man is as it were subdivided into many smaller ones, may possibly be, that as the guts of a human body are proportionally much longer than those of this creature, it would have been inconvenient to have gathered all the lactea primi generis into one place, whereas by collecting a few of these vessels into a neighbouring gland the same effect is procured much more easily.

The pancreas in man lies cross the abdomen, tied down

¹⁸
Pancræs. down by the peritoneum; but the capacity of this creature's abdomen not allowing of that situation, it is disposed more longitudinally, being tied to the duodenum which it accompanies for some way. Its duct enters the duodenum about half an inch below the others.

¹⁹
Spleen. The spleen of this animal differs from ours very much, both in figure and situation. It is much more oblong and thin, and lies more according to the length of the abdomen, like the pancreas. Though the spleen of this creature is not firmly tied to the diaphragm, (which was necessary in our erect posture to hinder it from falling downwards), yet by the animal's prone position, its posterior parts being rather higher than the anterior, it comes to be always contiguous to this muscle, and is as effectually subjected to an alternate pressure from its action as the human spleen is.

²⁰
Liver. The human liver has no fissures or divisions, unless we reckon that small one betwixt the two pylæ, where the large vessels enter: whereas in a dog and all other creatures that have a large flexion in their spine, as lions, leopards, cats, &c. the liver and lungs are divided into a great many lobes by deep sections, reaching the large blood-vessels, which in great motions of the back-bone may easily shuffle over one another, and so are in much less danger of being torn or bruised than if they were formed of one entire piece, as we really see it is in horses, cows, and such creatures as have their back-bone stiff and immoveable. There is here no ligamentum latum connecting the liver to the diaphragm, which in our situation was necessary to keep the viscus in its place; whereas in this creature it naturally gravitates forwards, and by the horizontal position of the animal is in no danger of pressing against the vena cava: the preventing of which is one use generally assigned to this ligament in man. Had the liver of the dog been thus connected to the diaphragm, the respiration must necessarily have suffered; for as we shall see afterwards, this muscle is here moveable at the centre, as well as at the sides: but in man the liver is fixed to the diaphragm, mostly at its tendinous part; that is, where the pericardium is fixed to it on the other side: so that it is in no danger of impeding the respiration, being suspended by the mediastinum and bones of the thorax. In consequence of this viscus being divided into so many lobes, it follows that the hepatic ducts cannot possibly join into one common trunk till they are quite out of the substance of the liver.

²¹
Kidneys. We come next, after having examined the chylipoietic viscera, to discourse of those organs that serve for the secretion and excretion of urine, and first of the kidneys, which in this animal are situated much in the same way as in the human subject, but have no fat on their inferior surface, where they face the abdomen, and are of a more globular form than the human. The reason of these differences will easily appear, if you compare their situation and posture in this animal with those in a man who walks erect. They are placed in this subject in the inferior part of the body, so are not subject to the pressure of the viscera, which seems to be the principal cause of the fatness of those organs in us; and perhaps may likewise be the cause of our being more subject to the stone than

other animals. Hence there is no need of any cellular substance to ward off this pressure where there would necessarily be fat collected; but the superior part of their kidneys is pretty well covered with fat, lest they should suffer any compression from the action of the ribs and spine.

In the internal structure there is still a more considerable difference; for the papillæ don't here send out single the several tubuli uriniferi, but being all united they hang down in form of a loose pendulous flap in the middle of the pelvis, and form a kind of septum medium; so that a dog has a pelvis formed within the substance of the kidney. The only thing that is properly analogous to a pelvis here, is that sac or dilatation of the ureters formed at the union of the ductulæ uriniferæ. The reason of these particularities may probably be, that the liquors of this animal, as of all those of the carnivorous kind, being much more acrid than those that live on vegetable food, its urine must incline much to an alcalescency; as indeed the smell and taste of that liquor in dogs, cats, leopards, &c. evidently shew, being fetid and pungent, and therefore not convenient to be long retained in the body. For this end it was proper, that the secreting organs should have as little impediment as possible by pressure, &c. in the performing their functions; and for that design, the mechanism of their kidneys seems to be excellently adapted: we have most elegant pictures in Eustachius of the kidneys of brutes delineated, as such, with a view to shew Vesalius's error in painting and describing them for the human.

The glandule or capsule atrabiliaræ, are thicker and rounder than the human, for the same reason as the kidneys.

The ureters are more muscular than the human, because of the favourable passage the urine has through them: they enter the bladder near its fundus.

The bladder of urine differs considerably from the human; and first in its form, which is pretty much pyramidal or pyriform: this shape of the dog's bladder is likewise common to all quadrupeds, except the ape and those of an erect posture. In men it is by no means pyriform, but has a large sac at its posterior and inferior part: this form depends entirely on the urine gravitating in our erect posture to its bottom, which it will endeavour to protrude; but as it cannot yield before, being contiguous to the os pubis, it will naturally stretch out where there is the least resistance, that is, at the posterior and lateral parts; and were it not for this sac we could not come at the bladder to extract the stone either by the lesser or lateral operation of lithotomy. Most anatomists have delineated this wrong, so that scarce any have justly painted it, excepting Mr Cowper in his Myotomia, and Mr Rully.

It has certainly been from observing it in brutes, and young children, that they have been led into this mistake. The same cause, viz. the gravity of the urine, makes the bladder of a different form in brutes; in their horizontal position the cervix, from which the urethra is continued, is higher than its fundus, the urine must therefore distend and dilate the most depending part by its weight.

As to its connection, it is fastened to the abdominal muscles by a process of the peritoneum, and that membrane

on.
brance

brane is extended quite over it; whereas in us its superior and posterior parts are only covered by it: hence in man alone the high operation of lithotomy can be performed without hazard of opening the cavity of the abdomen. Had the peritonæum been spread over the bladder in its whole extent, the weight of the viscera in our erect posture would have so bore upon it, that they would not have allowed any considerable quantity of urine to be collected there; but we must have been obliged to discharge its contents too frequently to be consistent with the functions of a social life. Whereas by means of the peritonæum the urine is now collected in sufficient quantity, the viscera not gravitating this way.

It may be taken for a general rule, that those creatures that feed upon animal food have their bladder more muscular and considerably stronger, and less capacious than those that live on vegetables, such as horses, cows, swine, &c. whose bladder of urine is perfectly membranous, and very large. This is wisely adapted to the nature of their food; for in these first, as all their juices are more acrid, so in a particular manner their urine becomes exalted, which as its remora might be of very ill consequence must necessarily be quickly expelled. This is chiefly effected by its stimulating this viscus more strongly to contract, and so discharge its contents. That a stimulus is one of the principal causes of the excretion of urine, we learn from the common saline diuretic medicines that are given, which are dissolved into the serum of the blood, and carried down by the kidneys to the bladder: the same appears likewise from the application of cantharides, or without any of these, when the parts are made more sensible, as in an excoriation of the bladder, there is a frequent desire to make water. Accordingly we find these animals evacuate their urine much more frequently than man, or any other creature that lives on vegetable food. And if these creatures, whose fluids have already a tendency to putrefaction, are exposed to heat or hunger, the liquids must for a considerable time undergo the actions of the containing vessels, and frequently perform the course of the circulation without any new supplies of food; by which the fluids becoming more and more acrid, the creature is apt to fall into feverish and putrid diseases. These causes have been thought sufficient to produce that fatal and melancholy distemper the *rabies canina, vulpina*, &c. in such animals; whereas those that feed on vegetable food seldom or never contract these diseases but by infection. That the causes commonly assigned for the *rabies canina* are insufficient to produce it in dogs and other animals of that kind, is denied in a dissertation on this disease by Dr Heysham. That heat is insufficient, he proves from the disease being totally unknown in South America, where the heat is much greater than in this country. Putrid aliment he also says is taken in great quantity by dogs without any inconvenience; and as it seems in this state to be most agreeable to them, the *rabies canina* cannot with any probability be ascribed to it. As to want of water, he observes that the disease often originates among dogs that are plentifully supplied with that element, while others long deprived of it have remained perfectly free. In short,

Dr Heysham totally denies, not only the efficacy of the causes commonly assigned for the *rabies canina*, but the nature of the distemper itself; and conjectures that the cause of it is not a *putrescency* but an *acidity* of the fluids. See (the *Ind.* x subjoined to) MEDICINE.

The spermatic vessels are much the same way disposed as in us; they are contained within the cavity of the abdomen, as the guts are within the peritonæum, which is spread over them, and from which they have a membrane like a mesentery, so hang loose and pendulous in the abdomen: whereas in us they are contained in the cellular part of the peritonæum, which is tensely stretched over them. At their passage out of the lower belly, there appears a plain perforation or holes; and from observing this in quadrupeds has arisen the false notion of hernia or rupture among authors. This opening is of no disadvantage to them, but evidently would have been to us; for, from the weight of our viscera continually gravitating upon these holes, we must have perpetually laboured under enterocœles; this they are in no hazard of, since in them this passage is at the highest part of their belly, and in their horizontal posture, the viscera cannot bear upon it: and to prevent even the smallest hazard, there is a loose pendulous femilunar flap of fat which serves two uses, as it both hinders the intestines from getting into the passage, and also the course of the fluids from being stopped in the vessels, which is secured in us by the cellular substance and tense peritonæum.

The septum medium, or conjunction of the two tunics, is the same as in men. There is next a passage quite down into the cavity, where the testicles lie. Had the same structure obtained in man, by the constant drilling down of the liquor which is secreted for the lubricating of the guts, we should always have laboured under an hydrocele; but their posture secures them from any hazard of this kind: indeed your very fat lap-dogs, who consequently have an overgrown omentum, are sometimes troubled with an epiplocele.

The scrotum is shorter and not so pendulous as the human, this it has in common with all the dog kind that want the vesiculæ seminales, who have it pretty close tucked up, that the seed at each copulation might the sooner be brought from the testes, thus in some measure supplying the place of the vesiculæ seminales; for the course of the seed through the *vasa deferentia* is thus shortened by placing the secretory vessels nearer the excretory organs. This at the same time explains the reason why this creature is so tedious in copulation.

The structure of the testicles is much the same with the human; as are likewise the corpus pyramidalis varicosum or pampiniforme, and the epididymis or excretory vessel of the testicle; the *vasa deferentia* enter the abdomen where the blood vessels come out, and passing along the upper part of the bladder, are inserted a little below the bulbous part of the urethra.

The præputium has two muscles fixed to it; one that arises from the sphincter ani, and is inserted all along the penis, and this is called *retractor præputii*, but the other, whose office is directly contrary to this, is cutaneous, and seems to take its origin from the muscles of the abdomen, or rather to be a production

of their tunica carnofa. The corpora cavernofa rife much in the fame way as the human; but thefefoon terminate, and the reft is fupplied by a triangular bone, in the inferior part of which there is a groove excavated for lodging the urethra. There are upon the penis two protuberant bulbous flefhy fubftances, at the back of which are two veins, which by the ereftores penis are compreffed in the time of coition, and the circulation being ftopped, the blood diftends the large cavernous bodies: after the penis is thus fwelled, the vagina, by its contraction, gripes it clofely, and fo the male is kept in action fome time contrary to his will; till time be given for bringing a quantity of feed fufficient to impregnate the female; and thus by that orgasmus veneris of the female organs, the want of the veficulae feminales are in fome meafure fupplied. But as it would be a very uneasy pofture for the dog to fupport himfelf folely upon his hinder feet, and for the bitch to fupport the weight of the dog for fo long a time; therefore as foon the bulbous bodies are fufficiently filled, he gets off and turns averfe to her; had then the penis been pliable as in other animals, the urethra muft of neceffity have been compreffed by this twifting, and confequently the courfe of the feed intercepted; but this is wifely provided againft by the urethra's being formed in the hollow of the bone. After the emission of the feed, the parts turn flaccid, the circulation is reftored, and the bulbous parts can be eafily extended.

38
Profrata.

The profrata feems here divided into two, which are proportionally larger than the human, and afford a greater quantity of that liquid.

39
Uterus.

The uterus of multifarious animals is little elfe but a continuation of their vagina, only feparated from it by a fmall ring or valve. From the uterus two long canals mount upon the loins, in which the fœtus's are lodged; thefe are divided into different facs, which are ftrongly conftriated betwixt each facus, yet thefe conftriations give way in the time of birth. From thefe go out the tubæ Fallopiæ; fo that the ovaria come to lodge pretty near the kidneys.

40
Diaphragm

We ought next to examine the ftructure of the thorax and its contents; but firft it may not be amifs to remark of the diaphragm in its natural fituation, that it is in general more loofe and free than the human, which is owing to its connection with the neighbouring parts in a different manner from ours; the human diaphragm is connected to the pericardium, which again by the intervention of the mediastinum is tied to the fternum, spine, &c. but here there is fome diftance between the diaphragm and pericardium. We obferve further that its middle part is much more moveable, and the tendinous parts not fo large. And indeed it was neceffary their diaphragm fhould be fomewhat loofe, they making more ufe of it in difficult refpiration than man. This we may obferve by the ftrong heaving of the flanks of an horfe or dog when out of breath; which corresponds to the rifing of the ribs in us.

41
Thorax.
42
Mammæ.

The difpofition and fituation of the mammæ vary as they bear one or more young. Thofe of the uniparous kind have them placed between the pofterior extremities, which in them is the higheft part of their bodies, whereby their young get at them without the

inconvenience of kneeling; nevertheless, when the creatures are of no great fize, and their breaft large, as in fheep, the young ones are to take this pofture. In multifarious animals they muft have a great number of nipples, that their feveral young ones may have room at the fame time, and thefe difpofed over both thorax and abdomen; and the creatures generally lie down when the young are to be fuckled, that they may give them the moft favourable fituation. From this it does not appear to be from any particular fitnefs of the veffels at certain places, for giving a proper nourifhment to the child, that the breafts are fo placed in women, as we find them, but really from that fituation being the moft convenient, both for mother and infant.

43
Sternum
Coflæ.

The fternum is very narrow, and confifts of a great number of fmall bones, moveable every way, which always happens in creatures that have a great mobility in their fpine. The ribs are freighter and by no means fo convex as the human, whereby in refpiration the motion forward will very little enlarge their thorax, which is compensated by the greater mobility of their diaphragm; fo our thorax is principally enlarged according to its breadth and depth, and theirs according to its length. The want of clavicles, and the confequent falling in of the anterior extremities upon the cheft, may contribute fomewhat to the freightnefs of the ribs.

44
Mediastinum.

The mediastinum in this creature is pretty broad, whereas the human being fo narrow has occafioned a difpute whether there be fuch a thing or not. The pericardium is not here contiguous to the diaphragm, but there is an inch of diftance betwixt them, in which place the fmall lobe of the lungs lodges, and by this means the liver, &c. of this animal, though continually preffing upon the diaphragm, yet cannot difturb the heart's motion.

45
Cor.

The heart is fited with its point almoft directly downwards, according to the creature's pofture, and is but very little inclined to the left fide. Its point is much fharper, and its fhape more conoidal than the human. Here the names of right and left ventricles are proper enough, though not fo in the human, which ought rather to be called anterior and pofterior, or fuperior, and inferior. The animal has the vena cava of a confiderable length within the thorax, having near the whole length of the heart to run over ere it gets at the finus lowerianus dexter. In men, as foon as it pierces the diaphragm, fo foon it enters the pericardium, which is firmly attached to it, and immediately gets into the finus Lowerianus; which finus in the human fubject, by the oblique fituation of the heart, is almoft contiguous to the diaphragm, and by this we difcover that feveral authors have taken their delineations of the human heart from brutes, which is eafily detected by the fhape and fituation of the heart, and long vena cava within the thorax.

46
Vena Cava.

This fituation of the heart of the creature agrees beft with the fhape of its thorax, which is lower than the abdomen.

47
Aorta afcendens improperly fo called.

The egress of the large blood-vessels from the heart is fomewhat different from the human, for here the left fubclavian comes off firft, and then a large trunk runs fome way upwards before it gives off the left carotid,

carotid, and splits into the carotid and subclavian of the right side : so that neither here, properly speaking, is there an aorta ascendens, more than in the human ; but this name has probably been imposed upon it from observing this in a cow, where indeed there is an ascending and descending aorta.

From this speciality of the distribution of the vessels of the right side, which happens, though not to so great a degree, in the human subject, we may perhaps in some measure account for the general greater strength, readiness or faculty of motion which is observable in the right arm. Upon measuring the sides of the vessels, the surface of the united trunk of the right subclavian and carotid is less than that of the left subclavian and carotid, as they are separated ; if so, the resistance to the blood must be less in that common trunk than in the left subclavian and carotid ; but if the resistance be smaller, the absolute force with which the blood is sent from the heart being equal, there must necessarily be a greater quantity of blood sent through them in a given time : and as the strength of the muscles is, *cæteris paribus*, as the quantity of blood sent into them in a given time, those of the right arm will be stronger than those of the left. Now, children being conscious of this superior strength, use the right upon all occasions ; and thus from use comes that great difference which is so observable. That this is a sufficient cause seems evident from fact ; for what a difference is there betwixt the right and the left arm of one, who has played much at tennis ? View but the arms of a blacksmith, and legs of a footman, and you'll soon be convinced of this effect arising from using them. But if by any accident the right arm is kept from action for some time, the other from being used gets the better, and those people are left-handed : for it is not to be imagined that the small odds in the original formation of the vessels should be sufficient to resist the effect of use and habit, (instances of the contrary occur every day) ; 'tis enough for our present argument, that where no means are used to oppose it, the odds are sufficient to determine the choice in favour of the right. Now because it is natural to begin with the leg corresponding to the hand we have most power of, this is what gives also a superiority to the right leg.

This difference is not peculiar to man, but is still more observable in those creatures, in whom the same mechanism does obtain in a greater degree. Do but observe a dog at a trot, how he bears forwards with his right side ; or look at him when a-scraping up any thing, and you will presently see that he uses his right much oftner than he does his left foot. Something analogous to this may be observed in horses.

The thymus of this creature is proportionably much larger than ours, whereas the glandula thyroidea is much less, and it is generally remarked that these two glands do thus always supply the place of each other : that is, in such animals as have a large thymus ; the glandula thyroidea is smaller, and *vice versa*. Hence we are naturally led to ascribe the same use to both, *viz.* the separation of a thin lymph for diluting the chyle in the thoracic duct, before it be poured into the blood ; then if we consider the different formation of the thorax in both, we shall readily account for the

variety in the bulk of these two glands. Respiration being chiefly performed in man by the widening of the chest, the lungs at every inspiration must press upon the thymus, and consequently diminish it ; but the diaphragm yielding more in the dog's inspiration, this gland is not so much pressed by the lungs and so will be larger, and hence the glandula thyroidea will be proportionably less : again, from the posture of this creature, we shall see that it was much more convenient for a dog to have the most part of the diluting lymph supplied by the thymus, since the neck being frequently in a descending posture, the lymph of the thyroid gland would have a very disadvantageous course to get to the thoracic duct : whereas in the human body, the thymus is really below the lacteal canal, where it makes its curvature before it opens into the subclavian, and consequently there is a necessity of a considerable share of the diluting liquor being furnished by the thyroid gland, which is situated much higher, so that its lymph has the advantage of a perpendicular descent.

We may here observe that the thoracic duct in a dog has no curvature before it enters the subclavian vein. The horizontal position of this animal allowing a favourable enough course to the chyle, so as not to need that turn to force its passage into the blood. The lungs of this creature are divided into more numerous lobes and deeper than they are in man, for the same reason as the liver. The left side of the thorax in this animal bears a greater proportion to the right than in man, the one being nearly as three to two, the other as four to three.

We look on it as a general rule, that all quadrupeds, as having occasion to gather their food from the ground, are provided with longer necks than man ; but as a long neck not only gives the advantage of too long a lever to the weight of the head, but also when the animal is gathering his food, makes the brain in danger of being oppressed with too great a quantity of blood, by the liquor in these arteries having the advantage of a descent, while that in the veins must remount a considerable way contrary to its own gravity ; it was therefore necessary that a part of the length of the neck should be supplied by the length of the jaws. Thus we see horses, cows, &c. who have no occasion for opening their mouths very wide, yet have long jaws. Bull dogs indeed, and such animals as have occasion for very strong jaws, must of necessity have them short ; because the longer they are, the resistance to be overcome acts with a longer lever. Another exception to this general rule, is, such animals as are furnished with something analogous to hands to convey their food to their mouths, as cats, apes, &c. The teeth of this creature plainly shew it to be of the carnivorous kind, for there are none of them made for grinding their food, but only for tearing and dividing it. Even its posterior teeth are not formed with rough broad surfaces as ours are ; but are made considerably sharper, and press over one another when the mouth is shut ; that so they may take the firmer hold of whatever comes betwixt them.

The tongue in consequence of the length of the jaws, is much longer than ours ; and as this creature feeds with his head in a depending posture, the bolus would

would always be in danger of falling out of the mouth, were it not for several prominences placed mostly at the root of the tongue, and crooked backwards in such a manner as to allow any thing to press easily down to the jaws; but to hinder its return. In some animals who feed on living creatures, these under hooks are still more conspicuous; as in several large fishes, where they are almost as large as their teeth in the forepart of their mouth, and near as firm and strong.

56
Amygdals. When we open the mouth, we see the amygdals very prominent in the posterior part of it; so that it would appear at first view, that these were inconveniently placed, as being continually exposed to injuries from the hard substances this creature swallows; but upon a more narrow scrutiny we find this provided for by two membranous capsulæ, into which the amygdals, when pressed, can escape and remove themselves from such injuries.

57
Velum pendulum palati. The velum pendulum palati, is in this creature considerably longer than in man, to prevent the food from getting into his nose; which would happen more frequently in this animal than in man, because of its situation while feeding.

58
Glottis. In this subject there is no uvula; but then the epiglottis, when pressed down, covers the whole rima entirely, and naturally continues so; there is therefore a ligament, or rather muscle, that comes from the os hyoides and root of the tongue, that is inserted into that part of the epiglottis where it is articulated with the cricoid cartilage, which serves to raise it from the rima, though not so strongly but that it may with a small force be clapt down again. If then in all such animals as have no uvula, the epiglottis is so ordered as to be capable of covering the rima entirely, and if in man the epiglottis cannot be so pressed backwards and downwards, as to shut up the glottis perfectly, but leaves a space that can be exactly filled up by the uvula, we may very reasonably conclude that the use of this part is to supply this deficiency in the epiglottis.

60
The use of the uvula in man. In the upper part of the pharynx, behind the cricoid cartilage, there is a pretty large gland to be found, which serves not only for the separation of a mucous liquor to lubricate the bolus as it passes this way, but also supplies the place of a valve, to hinder the food from regurgitating into the mouth, which it would be apt to do by reason of the descending situation of the creature's head.

61
Œsophagus. The œsophagus is formed pretty much in the same way as the human; authors indeed generally alledge, that quadrupeds have their gullet composed of a double row of spiral fibres decussing one another; but this is proper to ruminating animals, who have occasion for such a decussation of fibres. The action of these may easily be observed in a cow chewing her cud.

62
Organ of smell. The nose is generally longer than in man, and its external passage much narrower. The internal structure is also better adapted for an acute smelling, having a larger convoluted surface on which the membrana Scheideriana is spread, and this is to be observed in most quadrupeds, who have the ossa spongiosa commonly large, and these too divided into a great number of excessively fine thin lamellæ. The ele-

phant, which has a head pretty large in proportion to its body, has the greatest part of it taken up with the cavity of the nose and frontal sinusses, which last extend almost over their whole head, and leaves but a small cavity for their brains. A very nice sense of smelling was not so absolutely necessary for man, who has judgment and experience to direct him in the choice of his food; whereas brutes, who have only their senses, must have these of necessity acute, some having one sense in greater perfection than others, according to their different way of life. We not only conclude *a priori* from the large expanded membrana Scheideriana that their sense of smelling is very acute, but we find it so by cows, and horses, distinguishing so readily betwixt noxious and wholesome herbs, which they do principally by this sense.

The external ear in different quadrupeds is differently framed, but always calculated to the creature's manner of life: in shape it commonly resembles the oblique section of a cone from near the apex to the basis. Hares and such other animals as are daily exposed to insults from beasts of prey, have large ears directed backwards, their eyes warning them of any danger before; rapacious animals, on the other hand, have their ears placed directly forwards, as we see in the lion, cat, &c. The slow hounds and other animals that are designed to hear most distinctly the sounds coming from below, have their ears hanging downwards. Man again, who must equally hear sounds coming from all quarters, but especially such as are sent from about his own height, has his external ear placed in a vertical manner, somewhat turned forward. In short, where-ever we see a speciality in the make of this organ in any creature, we shall with very little reflection discover this form to be more convenient for that creature than another. There are some differences to be observed in the structure of the internal ear, in different animals; but we know so very little of the use of the particular parts of that organ in the human subject, that it is altogether impossible to assign reasons for these variations in other creatures.

All quadrupeds have at the internal canthus of the eye, a strong firm membrane with a cartilaginous edge, which may be made to cover some part of their eye, and this is greater or less in different animals, as their eyes are more or less exposed to dangers in searching after their food: this *membrana nictitans*, as it is called, is not very large in this animal; cows and horses have it so large as to cover one half of the eye like a curtain, and at the same time is transparent enough to allow abundance of the rays of light to pass through it; fishes have a cuticle always over their eyes, as they are ever in danger in that inconstant element. In this then we may also observe a sort of gradation.

All quadrupeds have a seventh muscle belonging to the eye, called *suspensorius*. It surrounds almost the whole optic nerve, and is fixed into the sclerotic coat as the others are; its use is to sustain the weight of the globe of the eye, and prevent the optic nerve being too much stretched, without obliging the four straight muscles to be in a continual contraction, which would be inconvenient. At the same time this muscle

63

Membrana nictitans.65
Musculus suspensorius.

66
Pupilla.

may be brought to assist any of the other four, by causing one particular portion of it to act at a time.

The next thing to be remarked, is the figure of the pupil, which is different in different animals, but always exactly accommodated to the creature's way of life. Man has it circular for obvious reasons; an ox has it transverse, to take in a larger view of his food; cats again have theirs somewhat perpendicular, (but can alter it pretty much) for a similar reason, and so of the rest: the pupil of different animals varies in wideness according as the internal organs of vision are more or less acute; thus cats and owls who seek their prey in the night, or in dark places (and consequently must have their eyes so formed as that a few rays of light may make a lively impression on the retina) have their pupils in day-time contracted into a very narrow space, as a great number of rays would oppress their nice organs, while in the night they dilate considerably. In the same way when the retina is inflamed, a great number of rays of light would occasion a painful sensation, therefore the pupil is contracted; on the contrary in dying people, or in a beginning amaurosis it is greatly dilated, as the eyes on such occasions are very difficultly affected, and as it were insensible.

67
Tapetum.

The posterior part of the choroid coat, which is called *tapetum*, is of different colours in different creatures. Or oxen feeding mostly on grass have this membrane of a green colour, that it may reflect upon the retina all the rays of light which come from objects of that colour, while other rays are obscured: thus the animal sees its food better than other objects. Cats and owls have their tapetum of a whitish colour, and for the same reasons have the pupil very dilatible, and their organs of vision acute; and we shall find that all animals see more or less distinctly in the dark, according as their tapetum approaches nearer to a white or black colour. Thus dogs who have it of a greyish colour distinguish objects better in the night than man, whose tapetum is dark brown, and who we believe sees worst in the dark of any creature: it being originally designed that he should rest from all kinds of employments in the night-time. The difference then of the colour of the tapetum, as indeed the fabric of any other part in different creatures, always depends on some particular advantage accruing to the animal in its peculiar manner of life from this singularity.

68
Cerebrum.

We shall now proceed to the brain, which we remark in the first place is proportionally much smaller in all quadrupeds than the human. The reason of which may be, that as those creatures for the most part seek their food with their heads in a depending posture, this situation would make it very inconvenient for the brain itself to send its animal spirits, (or its influence and energy, let that be what it will) through the nerves, so that it was necessary they should be supplied from somewhere else; and consequently there was no reason for the brain itself being of a great bulk. As a confirmation of this theory, we find that the intercostal and eight pair of nerves, which serve the vital organs in the human body, take their origin from the encephalon, which in quadrupeds come mostly from the *theca vertebrae*. Again there was no such occasion for so great a quantity of brains in those animals as in man; seeing in them all its energy is em-

ployed in their progression, while man has a great waste of spirits in the exercise of his reason and intellectual faculties. And besides all this, a great bulky brain would be inconvenient to these creatures, in so far as it would add considerably to the weight of the head, which having the advantage of a long lever to act with, would require a much greater force to support it, than now it does; for the heads of the greatest part of quadrupeds are not near so heavy as they would at first seem to be, from the *sinus frontales* being produced a great way upwards to enlarge the organs of smelling.

The pits in the anterior part of their skulls are much more conspicuous than in the human *cranium*, which may be occasioned by the depending posture of these creatures heads, while they gather their food: the brain at this time gravitating much on the bones while they are as yet soft, will gradually make impressions upon them at these places where it rises into eminences. This is prevented in man mostly by his erect posture.

The falx is not near so large in quadrupeds as in man, as they have little occasion to be on either side; and the two hemispheres of the brain are in a great measure hindered from jutting against one another in violent motions, by the brain's insinuating itself into the above-mentioned pits.

The second process of the *dura mater*, or *tentorium cerebelli superexpansum* is considerably thicker and stronger in most quadrupeds than in man, especially in such of them as are very swift of foot, as hares and rabbits, and that most when they are old. This membrane is generally ossified, that it may the more effectually keep off the weight of the superincumbent brain from the *cerebellum* in their rapid motions, which otherwise would be of bad consequence.

The olfactory nerves are very large, and justly deserve the name of *processus mammillaris*. They are hollow, and consist of a medullary and cineritious substance; and at first sight appear to be anterior ventricles of the brain produced; but in man they are small, and without any discernable cavity. The reason of this is pretty evident, if we consider how this animal's head is situated; for the lymph continually gravitating upon the inferior part of the ventricles may thus elongate and produce them: but from this very inferior part the olfactory nerves rise, and are sent immediately through the os ethmoides into the nose. Hence the ancients thinking they were continued hollow into the nose, believed they were the emanatories of the brain. In the brain of sheep, which by its firm texture is the best subject of any for searching into the structure of this part, we evidently see, that the name of the sigmoid cavities was very properly applied by the ancients to the lateral ventricles of the brain, which are really of a greater extent than they are ordinarily painted by the anatomists, reaching farther backwards and forwards again under the substance of the brain.

The nates and testes deserve this name much better here than in the human body with respect to each other. They are here also of different colours, the nates being of the colour of the cortical, and the testes of the medullary substance of the brain: whereas in man they are both of one colour. The reason of these differences,

69
Falx.

70
Processus
mammillaris.

71
Nates.
Testes.

differences, and others of the like nature to be met with, we shall not pretend to determine; for we have hitherto such an imperfect knowledge of the brain itself, that we are entirely ignorant of the various uses of its different parts; we may in general conclude, that the varying in one animal, from what it is in another, is fitted to the creature's particular way of living.

72 The rete mirabile Galeni, situated on each side of the fella turcica, about which there has been so much dispute, is more remarkable in quadrupeds than in the human subject, though it is certainly to be found there too; notwithstanding several anatomists have denied its existence. The use indeed which Galen ascribes to it is frivolous, and not well grounded; for he will have this plexus of vessels serve for checking the impetuosity of the blood in the brain; but it is evident this cannot be the use of it; if indeed the whole carotid artery had split into such small vessels as compose this network, the motion of the blood would certainly have been retarded in it; but this is not the case, for it only sends off a few small twigs to compose the plexus at its entry into the cranium; and the branches going out from this same plexus, are distributed to the neighbouring nerves: among the rest it gives some twigs to the ophthalmic branch of the fifth pair. It is this distribution of these arteries makes it so difficult to determine whether there is a communication between the intercostal and that nerve; for if you dissect the parts in a recent subject, you would at first view affirm, that there is an anastomosis; but when the carotid artery is injected, and the plexus filled with the fistule liquor, these branches, which formerly seemed to be nerves, have now the appearance of arteries by the vessels of their coats being injected.

The structure of the brain differing but very little in all quadrupeds, it will be needless to examine it in any other.

73 Chap. III. The Anatomy of a Cow.

The next species of quadrupeds we proposed to consider was the ruminant kind, of which we have an example in a cow; and accordingly shall take the fœtus of the animal in utero, that we may first remark some things that are peculiar to it in that state, and afterwards proceed to examine its viscera as a ruminant animal; first then as a fœtus.

74 The form of a cow's uterus differs from the human, in having two pretty large cornua. This is common to it with other brutes; for a bitch has two long cornua uteri; but these again differ (as being multiparous and uniparous) in this, that in the bitch's cornua the fœtuses are contained, whereas here there is only part of the secundines, being mostly the allantois with the included liquor. The muscular fibres of the uterus are more easily discovered; its internal surface has a great number of spongy, oblong, protuberant, glandular bodies fixed to it by a fine membrane: these are composed of the several large vessels of the uterus terminating here. These are very small, and sometimes not to be observed at all. In an impregnated uterus, we can easily press out of them a chylous mucilaginous liquor; they are composed of a great many processes or digituli, and deep caverns answering to as many processes and caverns of the placenta. Their resemblance

has occasioned the name of *Papillæ* to be given them; and hence it was that Hippocrates was induced to believe, that the fœtus sucked in utero. It is not easy to determine, whether the uterus grows thicker or thinner in the time of gestation. The membranes it is plain (by the stretching of the parts) must be made thinner; but then it is as evident, that the vessels are at that time enlarged, upon which principally the thickness of any part depends; so there seems to be as much gained the one way, as lost the other. The os uteri is entirely shut up by a glutinous mucilaginous substance, that is common to the females of all creatures when with young; by this the external air is excluded, which would soon make the liquors corrupt, it also prevents the inflammation of the membranes, and the hazard of abortion. By this means also the lips of the womb are kept from growing together, which otherwise they would certainly at this time do. There are mucous glands placed here to screen this gluten, which on the breaking of the membranes with the contained waters make a sapo that lubricates and washes the parts, and makes them easily yield. The first of the proper involucria of the fœtus is the chorion.

The chorion is a pretty strong firm membrane, on whose external surface are dispersed a great many red fleshy bodies of the same number, size and structure with the papillæ, with which they are mutually indented. They have been called *Golyedones* from *κολλη* cavity. This is greatly disputed by some as a name very improper, but without reason, since the surface that is connected to the papillæ is concave, though when separated it appears rather convex. To shun all dispute, they may be called properly enough *Placentule*, since they serve the same use as the placenta in women. The separation of these from the papillæ without any dilaceration seems to prove beyond a reply, that there can be here no anastomoses betwixt the vessels; on their coats run a great number of vessels, that are sent to the several placentulæ, on the external side next to the uterus; whereas in creatures that have but one placenta, as in the human subject, cats, dogs, &c. the adhesion is somewhat firmer: the placenta are likewise joined to the papillæ in the cornua uteri. We shall next give the history of the allantois.

75 The is a fine transparent membrane contiguous to the former. It is not a general involucrum of the fœtus in the mother; for it covers only a small part of the amnios: it is mostly lodged in the cornua uteri. In mares, bitches and cats, it surrounds the amnios, being every where interposed betwixt it and the chorion. In sheep and goats it is the same as in this animal; and in swine and rabbits it covers still less of the amnios. This fac is probably formed by the dilation of the urachus, which is connected at its other end to the fundus of the bladder, through which it receives its contents; and the membrane is doubled at the extremity of the canal to hinder the return of the urine back into the bladder. Its vessels are excessively fine and few, and we cannot force an injected liquor farther than the beginning of this coat. This membrane is so far analogous to the cuticula, as not to be liable to corruption, or easily irritated by acrid liquors. The existence of this membrane in women has

76 Uterus if thicker in time of gestation.

77 Chorion

78 Cotyledones.

79 Allantois.

72 rete mirabile Galeni.

74 Uterus.

75 cornua uteri.

83
The arguments for and against the human allantoidis.

has been very warmly disputed on both sides : those who are against its existence deny they could ever find it, and allowing it were so, allege, that since the urachus is impervious, as appears by our not being able to throw liquors from the bladder into it, or *vice versa*, it cannot serve the use, that is agreed by all it does serve in beasts, and therefore in the human body there is no such thing : but if we consider on the other hand, that first there seems to be the same necessity for such a reservoir in man, as in other animals. Secondly, That we actually find urine contained in the bladder of the human fœtus. Thirdly, That urine has been evacuated at the navel when the urethra was stopped, which urine without this conduit would have fallen into the cavity of the abdomen. Fourthly, That midwives do generally remark two different sorts of waters come away at the time of birth ; and lastly, That Dr Littré and Dr Hale have given in this membrane of an human subject, with all the other secundines curiously prepared, the one to the Royal Academy at Paris, the other to the Royal Society at London, by which societies their respective accounts are attested ; not to mention Verheyen, Heister, Keil, &c. who affirm their having seen it ; and Mr Albinus, that famous anatomist, professor at Leyden, is said to have shewn to his college every year a preparation of it. On all these accounts, it seems most probable, that there is such a membrane in the human body.

84
Amnios.

The third proper integument of the fœtus is the amnios ; it is thinner and firmer than the chorion ; it has numerous ramifications of the umbilical vessels spread upon it, the lateral branches of which separate a liquor into its cavity. This is the proper liquor of the amnios, which at first is in a small quantity, afterwards encreases for some months, then again decreases ; and in a cow near her time, the quantity of this liquor is not above a pound. This membrane does not enter the cornua uteri in this creature.

There are here two venæ umbilicales, but one in the human subject ; because the extreme branches coming from the several placentulæ could not unite, so soon, as they would have done, had they come all from one cake as in the human.

There is a small round fleshy body that swims in the urine of this creature, mares, &c. called *cuticula*, which is the hypomenes of the ancients. Several idle opinions and whims have been entertained as to its use ; but that seems to be still unknown, or how it is generated or nourished ; for it has no connection with the fœtus or placentule.

Having thus considered the several involucri of this animal in a fœtus state, let us next observe the specialities in its internal structure peculiar to a fœtus.

85
Vena umbilicalis.

The umbilical vein joins the vena portarum in the capsula glissoniana without sending off any branches as it does in the human subject. This vein soon after birth turns to a ligament, yet there are some instances where it has remained pervious for several years after birth, and occasioned an hemorrhage. We may next observe the duct called *canalis venosus*, going straight from the capsula glissoniana to the vena cava ; this turns also afterwards to a ligament. The umbilical arteries rise at acute angles from the internal iliacks,

whatever some may say to the contrary : these also become impervious.

The pulmonary artery coming from the right ventricle of the heart divides into two, the smallest called *canalis arteriosus* opens into the descending aorta ; the other divides into two, to serve the lung on each side. The foramen ovale is placed in the partition betwixt the right and left auricles. At the edge of this hole is fixed a membrane, which when much stretched will cover it all over, but more easily yields to a force that acts from the right auricle to the left, than from the left to the right. After what has been said, we may easily understand how the circulation is performed in a fœtus. The blood being brought from the placenta of the mother, is thrown into the capsula glissoniana, where it is intimately blended with the blood in the vena portarum : then part of this blood goes directly into the vena cava by the ductus venosus, the rest passes through the liver. First then the whole is sent from the vena cava into the right auricle, from whence part of it is sent by the foramen ovale into the left auricle ; the rest passes into the right ventricle ; then into the pulmonary artery ; then the greatest share it receives is sent immediately into the descending aorta by the canalis arteriosus ; and the remainder circulates through the lungs, and is sent back by the pulmonary veins into the left auricle ; which, with the blood brought there by the foramen ovale is sent into the left ventricle, from whence it is driven by the aorta through the body. The great design of this mechanism is, that the whole mass of blood might not pass through the collapsed lungs of the fœtus, but that part of it might pass through the foramen ovale and canalis arteriosus without circulating at all through the lungs.

This was the opinion that universally prevailed till the end of the last century, when it was violently opposed by Monsieur Mery, who is very singular in several of his opinions. He will not allow that the foramen ovale transmits blood from the right to the left auricle, but on the contrary from the left to the right ; and that for no other reason but because he observed the pulmonary artery in a fœtus longer than the aorta : Mr Winslow endeavours to reconcile these two opinions, by saying the blood may pass either way, and that it is here as it were blended ; his reason is, that on putting the heart in water, the foramen ovale transmits it any way. Mr Robault, professor of anatomy at Turin, and formerly one of Mery's scholars, strongly defends his master and criticises Mr Winslow. What he principally builds on is the appearance this foramen has in some dried preparations : this Mr Winslow won't allow as a proof. After all, the common opinion seems most probable ; and that for the following reasons : first the pulmonary artery being larger signifies nothing, since its coats are not only thinner, and will be more easily distended, but also the resistance to the blood in the pulmonary artery from the collapsed lungs is greater than the resistance to the blood in the aorta. Secondly, if we should allow any of these two uncommon opinions, we should have the right ventricle vastly more capacious than the left ; for if we suppose the foramen ovale to be capable of transmitting one half of the whole mass of blood in any given time, and the arteriosus as much in the

The circulation, how performed in a fœtus.

86
Messieurs Mery and Winslow, their opinions of examined.

87
Canalis venosus.

the same time; then, according to Mr Mery's opinion, the whole mass of blood being driven from the right ventricle into the pulmonary artery, one third passes by the canalis arteriosus into the descending aorta; two thirds passing through the lungs and returning into the left auricle, one half of it, or one third of the whole mass passes by the foramen ovale into the right auricle, and the other or the last third will be sent into the left ventricle, and thence expelled into the aorta; which third, with that from the pulmonary artery by the canalis arteriosus, circulating through the body, are returned into the right auricle, where meeting with the other third from the foramen ovale, with it are sent into the right ventricle to undergo the same course. Thus the whole mass is expelled by the right ventricle, and only one third by the left. If this was the case, why is not the right ventricle three times as large and strong as the left? Then, if according to Mr Winflow's system, the foramen ovale transmits equal quantities from both auricles, this comes to the same, as if there was no foramen ovale at all; that is to say, the whole mass going from the right auricle into the right ventricle and pulmonary artery, one third of the whole mass passes into the aorta through the canalis arteriosus, the other two thirds passing through the lungs, return to the left ventricle and auricle, to be sent through the canalis arteriosus to the right ventricle to undergo the same fate; thus the right ventricle expels the whole mass, the left only one third; but if according to the common opinion we suppose the foramen ovale to convey the blood from the right to the left auricle; then one third passes this way into the left ventricle, the other two thirds are sent by the right ventricle into the pulmonary artery, from whence one third passes by the canalis arteriosus into the aorta descendens, the other third circulates through the lungs and is returned into the left ventricle, where meeting with that from the foramen ovale, is with it expelled into the aorta; and with the one third transmitted by the canalis arteriosus returns into the auricle to run the same race as before. Thus we conclude that two thirds are expelled by each ventricle, and the whole circulates through the body; and hence they come to be of pretty equal dimensions. In all this calculation we have had no regard to the blood discharged from the umbilical vessels; but the greater quantity returned by the veins than sent out by the arteries still argues for the common opinion.

87
The kidneys.

The kidneys in the fœtus are composed of different lobes, which serves to give us an idea of the kidneys being a congeries of different glands; these lobes being kept contiguous by the external membrane are pressed by the other viscera till at length they unite.

88
The history of it as a ruminant animal.

We come now to consider the creature as a ruminant animal. There are no dentes incisores in the upper jaw, but the gums are pretty hard, their tongue rough; and they supply this defect by wrapping their tongue round a tuft of grass, or pressing it against the upper-jaw keep it stretched, and cut it with the teeth of the under-jaw; then, without chewing, throw it down into the œsophagus, which in these creatures consists of a double row of spiral fibres decussating one another. All animals which ruminate must have more

ventricles than one; some have two, some three; our present subject has no less than four. The food is carried directly down into the first, which lies upon the left-side and is the largest of all; it is called *ventriculus*, and *καλὴ* by way of eminence. It is what is called by the general name of paunch by the vulgar. There are no rugæ upon its internal surface; the food, by the force of its muscular coat, and the liquors poured in here, is sufficiently macerated, after which it is forced up hence by the œsophagus into the mouth; and there it is made very small by mastication; this is what is properly called chewing the cud, or rumination; after this it is sent down by the gullet into the second, for the œsophagus opens indifferently into both; however the creature has a power to direct it into which it will. Some tell us that the drink goes into the second; but that might be easily determined by making them drink before slaughter; the second stomach, which is the anterior and smallest, is called *κεντροφάδος reticulum*, the *bonnet* or *king's hood*. It consists of a great number of cells on its internal surface of a regular pentagonal figure, like to a honeycomb. Here the food is farther macerated, from which it is protruded into the third, called *exuvios* or *omasum*, *vulgo* the *manypilus*; because the internal surface rises up into a great many plizæ or folds, and *stratum super stratum*, according to the length of this stomach. Some of these plizæ are further produced into the stomach than others, *i. e.* first two long ones on each side, and within these, two shorter in the middle, &c. There are several glands in this stomach which is next to the *καλὴ* in bigness, and from this it passes into the fourth, whose names are *νοστρον*, *abomasium*, *caille*, or the *red*, which is the name it commonly has because of its colour. Caille signifies curdled; and hence the French have given that as a name to this fourth stomach; because any milk that is taken down by young calves from the long remora it makes here, turns acid; and by the remains of the milk before taken down, assisting, it is curdled. It is this fourth stomach with the milk curdled in it, that is commonly taken for earning of milk; (as they call it), but after the bile and pancreatic juice enter, this coagulation is not to be found, which shews the use of these liquors. There are other creatures that use the same food, that have not such a mechanism in their digestive organs; horses asses, &c. have but one stomach where grass is macerated, and a liquor for their nourishment extracted, and the remainder sent out by the anus very little altered. From this different structure of the stomach in these creatures, a ruminant animal will be served with one third less food than another of equal bulk; grassers are sufficiently acquainted with this. The reason is, that ruminating animals have many and strong digestive organs; all their food is fully prepared and almost converted into chyle; but a horse's stomach is not fitted for this, so that they require a much greater quantity of food to extract the same nourishment.

91
Intestina.

The guts of these creatures are of a considerable length in proportion to the bulk of the animal's body; and this confirms what we said formerly on the subject of the intestines of a dog, *viz.* that the length and capacity of the guts were different in different animals according to the nature of their food.

⁹²
Duodenum. The duodenum is formed here much the same way as in a dog, and the general intention kept in view; with regard to the mixture of the bile and pancreatic lymph. The great guts here hardly deserve that name, their diameter differing very little from that of the small ones; but to compensate this, they are much longer proportionally than a dog's are, being convoluted in the same way as the small guts are. The cæcum is very large.

⁹³
Spleen. The spleen differs not much either in figure or situation from that of a dog's; but it is a little more firmly fixed to the diaphragm, there not being here so much danger of this viscus being hurt in the flexions of the spine.

⁹⁴
Liver. The liver is not split into so many lobes in this creature as either in a man or dog, which depends on the small motion this creature enjoys in its spine, which made such a division needless.

⁹⁵
Bladder. Their vesica urinaria is of a pyramidal shape, and has scarce any muscular fibres. It is very large and membranaceous; for the urine of these creatures not being so acrid as that of carnivorous animals, there was no such occasion for expelling it so soon.

⁹⁶
Scrotum. Vesiculæ feminales. This creature is provided with a loose pendulous scrotum, and consequently with vesiculæ feminales. The female organs differ from those of a bitch, mostly as to the form of the cornua uteri, which are here converted in form of a snail. In this and all uniparous animals they contain only part of the fecundines; but in bitches and other multiparous animals they run straight up in the abdomen, and contain the fœtus themselves.

⁹⁷
Cor. The situation of the heart is pretty much the same with that of a dog, only its point is rather sharper; in us the heart beating continually against the ribs, and both ventricles going equally far down to the constitution of the apex it is very obtuse; but here the apex is made up only of the left ventricle, so is more acute.

⁹⁸
Aorta ascendens and descendens. The aorta in this creature is justly divided into ascending and descending, though this division is ill founded either in a dog or man; and it has certainly been from this subject that the older anatomists took

their descriptions when they made this division; for here the aorta divides into two, the ascending and descending: the descending runs upwards or forwards, according to their posture, for two or three inches, before it gives off the left subclavian; and still an inch or more before the right subclavian comes off, and yet somewhat further before it divides into the two carotids; so that the vessels that go to the anterior extremity of the right side, do still keep longer in a common trunk with the carotids than those on the left.

CHAP. IV. Of Fowls in general.

99

THE next class of animals we come to consider, are the feathered kind; which are divided into the granivorous and carnivorous. But before we go on to consider the specialties in the viscera of each kind, we must observe what both species agree in.

Fowls have a particular covering of feathers different from all other creatures, but exactly well suited to their manner of life; for it not only protects them from the injuries of the weather, but serves them in their progression through that thin aerial element, they are for the most part employed in; and as some fowls live much in the water, their feathers being continually besmeared with an oily liquor, keeps the water from soaking into their skins, and so prevents the bad effects which it would infallibly otherways produce.

Fowls have the strongest muscles in their whole body inserted into their wings; whence by the way we may observe, that it is altogether impossible for man to buoy himself up into the air like birds, even though he had proper machines in place of wings, unless he were likewise provided with muscles strong enough for moving them, which he has not.

In the next place, their wings are not placed in the middle of their bodies, but a good deal further forwards; whence it would at first view appear that their heads would be erect, and their posterior parts most depending, when raised in the air: but by stretching out their heads, which act upon the lever of a long neck, they alter their centre of gravity pretty much, and also by filling the sacs * or bladders in the inside of their

* Dr Hunter hath lately made some curious discoveries relative to these internal receptacles of air in the bodies of birds. Some of them are lodged in the fleshy parts, and some in the hollow bones; but all of them communicate with the lungs. He informs us, that the air-cells which are found in the soft parts have no communication with the cellular membrane which is common to birds as well as other animals. Some of them communicate immediately with each other, but all of them by the intervention of the lungs as a common centre. Some of them are placed in cavities, as the abdomen; others in the interstices of parts, as about the breast. The bones which receive air are of two kinds; some of them divided into innumerable cells; others hollowed out into one large canal. They may be distinguished from such as do not receive air by having less specific gravity; by being less vascular; by containing little oil; by having no marrow nor blood in their cells; by having less hardness and firmness than others; and by the passage for the air being perceivable.

The mechanism by which the lungs are fitted for conveying air to these cavities, is their being attached to the diaphragm, and connected also to the ribs and sides of the vertebrae. The diaphragm is perforated in several places by pretty large holes, allowing a free passage of air into the abdomen. To each of these holes is attached a distinct membranous bag, thin and transparent. The lungs open at their anterior part into membranous cells, which lie upon the sides of the pericardium, and communicate with the cells of the sternum. The superior parts of the lungs open into cells of a loose net-work, through which the trachea and œsophagus pass. When these cells are distended with air, it indicates passion, as in the case of the turkey-cock, pouting-pigeon, &c.

These cells communicate with others in the axilla, and under the large pectoral muscles; and those with the cavity of the os humeri, by means of small openings in the hollow surface near the head of that bone. Lastly, The posterior edges of the lungs have openings into the cells of the vertebrae, ribs, os sacrum, and other bones of the pelvis, from which the air finds a passage to the cavity of the thigh-bone.
